> *Resolved:* That within thirty days of his election, the incoming President shall appoint a Committee of three active members of the Association, whose duty it shall be to formulate such amendments to the constitution as may be deemed necessary, and to submit their report at the next semi-annual meeting of the Association; the amendments thus reported to be introduced at the semi-annual meeting, and lie over under the rules, and be considered at the next annual meeting of this Association.

The Chair announced the following committee on "Standard Methods of Wiring:" Messrs. DeCamp, Barton, Brophy, Law and Smith.

The report of the Committee on Incandescent Lamps was accepted and the Committee discharged with thanks.

---

[1] See page 235.

[2] See page 245.

The Committee on Legislation was continued.

It was agreed, on motion of Dr. Mason, that a committee of three on underground conduits and conductors be appointed to report at the next meeting.

Mr. Huntley, speaking on the subject referred to him at the last meeting, "How Can the National Electric Light Association Best Serve Central Station Interests," recommended that the advisability of having but one meeting a year be considered. He was not prepared to say that the time had arrived yet for that change, but he believed that it would soon come.

The President then introduced **Mr. Edward Weston**, who delivered a short address on "Electrical Measuring Instruments and their Methods of Use and Care."[1]

Mr. Weston was, by a rising vote, elected to honorary membership in the Association.

The President expressed his warm gratitude for the uniform courtesy and aid extended to him by the members of the Association and the Convention then adjourned *sine die*.

PRESIDENT PERRY'S RECEPTION.

The reception tendered the delegates on Wednesday evening, at Spink's Hall, by President Perry, will long be remembered as an occasion of the most perfect enjoyment by all present. It was an unqualified success from first to last.

The attendance was very large, the music and appointments of the best and the collation and vintage exquisite. The reception lasted from 8 o'clock to 11:30, and the music was furnished by the Hungarian Band from the Eden Musee, New York. The decorations were remarkably tasteful, the balcony being draped with smilax and the pillars adorned with clusters of roses and pinks. The chandeliers were decked with floral globes and bells.

The sight presented by the brilliant assemblage gathered together in the dancing and reception rooms was a beautiful and picturesque one and the galaxy of beauty was a stirring sight. President Perry made a prince of hosts and an evening of unsurpassed pleasure was spent by all.

THE RECEPTION AT THE AMERICAN ELECTRICAL WORKS.

The climax of the Convention festivities was reached in the complimentary reception Thursday evening by President Eugene F. Phillips of the American Electrical Works, at his factory on Stewart street. Owing to the increasing volume of business since the establishment of the concern, it has been found necessary to build a large addition to the five story structure, two floors of which were transformed into a brilliant hall for the guests.

The ball room covered an uninterrupted space of 146x60 feet, and much care had been taken in trimming the walls and ceiling in an artistic and attractive manner. The walls for the entire circuit were trimmed with flags wrought into butterflies, festoons and other picturesque designs, with Japanese parasols, shields and emblems set at frequent intervals. The stage occupied by the musicians was flanked by tropical plants and ferns in dense profusion. In the window recesses were set choice plants, orchids and other rare products of the conservatory. The shafting and pulleys on the ceiling were concealed beneath a drapery of bunting and violet globes depended from the spaces where the larger pulleys were hung. The hall was brilliantly lighted by hundreds of incandescent lamps, and the floor was highly polished for the dancers. Several apartments were reserved for the ladies and gentlemen as toilet, smoking and cloak rooms, and the floors leading to the ball and supper rooms were carpeted, for the protection of the ladies' costumes.

The grand march was begun at 9 o'clock, and at that time there were a company of over 400 guests, including Gov. Davis, ex-Mayors Hayward and Barker, President Perry, President Watson of the Common Council, Aldermen Winship and Fuller, Gardiner C. Sims, Hon. William A. Harris, Gen. C. H. Barney, and a number of others prominent in socal, professional and business circles. Then followed a long series of dances, in which fashionable figures predominated.

There was an intermission at midnight, and to the music of the orchestra, the company ascended to the supper hall where Gelb & Norton provided a choice collation. The dance favor was unique in design and workmanship, the covers being of drab chamois, decorated with an engraving of the works, the menu and list of committees and plan management. The reception committee was: Messrs. Marsden J. Perry, W. H. Sawyer, C. H. Barney, Allen R. Foote, E. A. Maher, A. J. De Camp, H. B. Cram, Charles W. Price, C. D. Haskins, S. A. Duncan, M. A. Knapp, C. R. Huntley, F. W. Webster, M. T. Pulsifer, C. L. Edgar, E. F. Peck, F. A. Gilbert, B. F. Hamilton, R. F. Ross, A. M. Young, H. H. Fairbanks, George C. Roe, A. D. Newton, E. D. Floyd and H. L. Luflin. The floor director was Mr. William A. Hathaway, and his aids were Messrs. P. C. Akerman, C. R. Remington, John Carroll, Lincoln V. Davis, E. Rowland Phillips, C. H. Wagenseil, Albert L. Capper, George H. Heathcote, H. A. Barker and Frank N. Phillips. The ball came to a successful termination at 2 o'clock, and the delegates retired enthusiastic in the opinion that Messrs. Phillips and Sawyer and their associates had once more exhibited perfect taste and tact as hosts and "entertainers by appointment to the electrical fraternity."

EXHIBITS.

Washburn & Moen Manufacturing Co., of Worcester, Mass., exhibited a very handsome case containing samples of all kinds of bare iron and copper wire from No. 40 gauge up to heavy stranded cables.

Sandford Electric Protector Co., of New York, exhibited a few samples of their protector which is claimed to be an absolute protection against lightning and all danger from excessive currents in telephone, fire alarm, and other low tension circuits.

Charles A. Schieren & Co., of New York, exhibited a number of samples of their favorite perforated belting, specially adapted to dynamo driving. They did not show any large belts, but showed a photograph of a battery of belts recently shipped for electrical purposes, the largest one being the 72-inch double belt for the Louisiana Electric Light Company, New Orleans, La. Messrs. C. A. Schieren, Jr., Mr. E. P. Atkinson and Mr. G. H. Hamblett were in attendance.

Russell Electric Lamp Co. showed two of their new disc carbon arc lamps, which are constructed with a view to burning for a long time without removing the carbons. Their ordinary 24-hour lamp and their more recent 10-hour "Baby" lamp for store purposes, were both shown in operation and attracted a great deal of favorable comment.

The Ellis Oil Filter Co. exhibited one of their special filters for central stations for filtering the oils after usage, so that they can be used over again.

The National Pipe Bending Co., of New Haven, Conn., manufacturers of the National Feed Water Heater, were represented by Col. S. J. Fox.

The Evans Friction Cone Co., of Boston, were represented by Mr. G. F. Evans the inventor of their frictional system of driving dynamos.

Steele & Johnson Manufacturing Co., of Waterbury, Conn., were represented by Mr. Albert H. Mills, who carried around with him for the inspection of his friends a select lot of samples of brass goods for electrical purposes.

The Simplex Electrical Co. exhibited a few sample reels of the famous "Simplex" wire, and were represented at the Convention by the ever popular Dr. A. F. Mason, and Mr. A. F. Talcott.

The Buckeye Electric Co., of Cleveland, O., were represented by their Eastern representative, Mr. Louis R. Wallis, who showed samples of incandescent lamps of all voltages and candle powers.

"The Western Electrician," occupied parlor No. 2 and was represented by Mr. W. A. Kreidler, John B. O'Hara, W. H. Temple and C. M. G. Paine. Mr. Kreidler had in his current issue achieved the unique distinction of carrying six pages from one advertiser.

Henry F. Jenks, of Pawtucket, R. I., exhibited one of his new improved drilling and tapping machines, which is specially adapted to the manufacture of electrical goods.

The Washington Electric Conduit Co., of Washington, D. C., exhibited samples of their glazed terra-cotta conduit, which has been extensively used for telephone and electric light purposes.

H. W. Johns Manufacturing Co., of New York, were represented by Mr. J. R. Burdick, who has been recently appointed to take charge of their Vulcabeston department, and all applications of their material for electrical purposes.

The Union Electric Manufacturing Co, Bridgeport, Conn., were represented by Mr. John M. Orford, who distributed a number of small cards printed on which were a number of strong claims, pertinently put, for the new switch, a sample of which Mr. Orford showed, though he carefully avoided showing the working parts. It is predicted that this switch will yet revolutionize the switch business, and if it accomplishes all that is claimed for it on the card mentioned above, there should be a large demand for it amongst the live members of the electrical fraternity.

The Clark Electric Co., of 192 Broadway, issued a very tasteful card, presenting in relief a view of one of the company's arc lamps mounted in an ornamental chandelier for interior lighting. Their fixtures are artistic in design and handsome in finish. A very valuable feature of the Clark lamp is that it can be operated from either arc or incandescent circuit. This gives them a wide application, as the running of arc lamps on incandescent circuits is deservedly becoming very popular.

---

[1] See page 244.

The Electric Merchandise Co., of Chicago, made a handsome exhibit in parlor 1 of their raw hide pinions, now so well and widely known as a *sine qua non* for street railways. They were ably represented by W. R. Mason, general manager of the company, and his versatile assistant, Mr. D. B. Dean, traveling representative.

The Insulite Mfg. Co., of New York, represented by Mr. Thos. Roebuck, showed their new "Insulite socket." The simplicity with which this socket is wired, and its positive insulation, particularly recommend it.

Mr. E. L. Powers, proprietor of our esteemed contemporary, *Electrical Industries*, Chicago, looked after the interest of his paper in a very thorough manner, and was assisted by Mr. E. E. Wood.

"The Electrical Review," of New York, was well represented by its staff as follows: Mr. Chas. W. Price, Mr. S. L. Coles, Mr. H. T. Richard, Mr. W. I. Barker, of Boston, and Mr. Geo. C. Maynard,, of Washington.

The American Electrical Works, Providence, had their headquarters in parlor 10, where every delegate was made welcome and presented with a box of candy. Upon opening this, however, and when about to enjoy the dainty caramel, he found himself met with a toughness as of their insulation, which prevented him luckily from swallowing the sermon contained inside. They also made a handsome exhibit in Union Hall. They were represented by Mr. Eugene F. Phillips, president; Mr. W. H. Sawyer, secretary; Mr. W. A. Hathaway, Mr. P. C. Ackerman, N. Y. agent, and Mr. John Carroll, secretary and treasurer of the Canadian company.

Mr. Myron A. Knapp, of the Knapp Electrical Works, Chicago, was out in force, and as usual surrounded by a host of friends.

The Electrical Supply Co., of Chicago, were represented at the meeting by Mr. Franklin S. Terry, manager, and Mr. Chas. Wirt, who displayed their new specialties and looked after everybody in their usual accomplished manner.

The American Oil Co., of Providence, exhibited samples of their dynamo, cylinder, and engine oil. Mr. J. C. Davis, treasurer, is looking after the interests of the company.

Mr. C. S. Van Nuis, perhaps better known by the classic name of "Ajax," made a handsome display of his Ajax switches and also the new lightning arrester, which, from personal observation, we may describe as a dazzling success.

Mr. L. E. Razee, of Boston, who deals largely in electrical supplies, was on hand.

Alexander, Barney & Chapin made a most comprehensive exhibit of their lines of supplies and new specialties. Their historic exhibit attracted the attention and commendation of all.

The E. S. Greeley Co., of New York, exhibited their high grade testing instruments, steam and electric railway and light supplies. Mr. F. A. Magee was on deck as usual looking after their interests, and Mr. Chas. P. Frey, their electrician, was with him.

The New York Insulated Wire Co. exhibited their well-known Grimshaw wires and cables. J. W. Godfrey, the manager, was on the ground looking after the "Nation's Choice."

The Crescent Insulated Wire and Cable Co., of Trenton, N. J., were represented by Mr. C. Edward Murray, president, and Mr. Thos. D. Reed, manager. They are making a new insulation having a process and special machinery for weaving a glass insulation on to the copper.

The Bryant Electric Co. had a handsome exhibit of their well-known switches and sockets.

Mr. George Cutter, of Chicago, the "electrical specialist" of the West, was right there, and had a most attractive exhibit of numerous good things, among them shades, railway trolley hangers, pole tops, the new globe holders and self-supporting arc lamp pulleys, and last, but by no means least, some of those prolifically fetching and enticing dodgers, such as the sleeping bull frog, the outcome of Mr. Cutter's fertile genius.

The Forest City Electric Works, Geneva, O., exhibited a 1,000 ampere double pole jaw switch of special construction, which is known as the Cleveland Duplex. Mr. Cleveland was showing up the merits of his switches.

The Engineering and Equipment Co., New York, showed samples of their indurated fibre pipe for conduits, which has been extensively used for this purpose. Mr. C. H. Sewall represented the company, assisted by Mr. Perrine, of Brooklyn.

The Illinois Electric Material Co., with their new catalogue reached every one's heart, and Mr. Ernest L. Clark, the secretary of the company, was around, and showed samples of their supplies and specialties, which he described in his typically graphic manner.

The Eureka Tempered Copper Co., of North East, Pa., made a fine display of tempered copper for all kinds of purposes. Mr. A. L. Daniels, noted for his genial qualities, had charge of the exhibit, and was assisted by Mr. N. Bushnell. The tensile strength of tempered copper is stated as 84,689 pounds to the square inch as compared with 19,872 pounds to the square inch of ordinary copper.

Mr. L. E. Wilcox, of L. E. Wilcox & Co., New Haven, Conn., showed the new speed wire stricker, which attracted lots of attention.

The Safety Insulated Wire & Cable Co., represented by Mr. W. G. Sellers, general agent, and Mr. Requa, general manager, exhibited coils and samples of their "Safety" seamless wires and cables for inside and line work.

The Standard Paint Co. had a display of "P & B" in many of its applications. The fine insulating and preservative qualities are known everywhere. Ralph L. Shainwald, president, and F. S. De Ronde were on hand.

The Phœnix Glass Co., of New York, made an elegant exhibit of their globes and shades for electric lighting. Mr. E. H. Peck represented them ably.

The Thermal Electric Co., of Gloucester, Mass., showed their multiple thermal cut-out.

The Jenney Electric Motor Co., of Indianapolis, was represented by Mr. Chas. D. Jenney, whose work in the electrical field has been of long standing and of the best. He exhibited one 3 h. p. and one 1 h. p., 500 volt machine, and a ¾ h. p. 110 volt motor. Their excellent work and beautifully smooth running attracted many favorable comments.

The Sperry Electric Co., of Chicago, had a most attractive show, and were represented by Mr. C. E. Gregory. A triple carbon lamp, a single carbon lamp, and the Sperry regulators were shown in operation.

The National Electric Protector Co., of New York, showed the Sanford electrical protector; Mr. C. E. Sanford, the inventor, was in attendance. This protector is of inestimable value for protecting telegraph and telephone circuits from dangerous currents.

Claflin & Kimball, Boston, New England agents of the Mather system, had a fine exhibit, in connection with that of the Parker Lamp Co., of their incandescent apparatus.

Lieut. H. K. Gilman, Mgr. of the Great Western Electric Supply Co., Chicago, was present and made a host of friends among those who now had the pleasure of greeting him in the East.

Col. J. H. Shay, of the Chas. Munson Belting Co., was right there all the time, booking orders and answering electrical conundrums. His rawhide canes vanished like smoke, and the factory is now running night and day to execute Col. Shay's promises.

The New York Insulated Wire Co. was well represented by Messrs. Place, Godfrey and Meeker. The company, through Mr. J. W. Godfrey, Gen'l Mgr., will shortly offer the trade a complete system of wire ducts for interior wiring of buildings. These tubes, or ducts, are to be known as "Vulcanoid Electric Wire Ducts." The material is said to be non-inflammable, waterproof, a perfect non-conductor, not affected by extreme heat or cold, or plaster, and pliable and smooth as glass. The compound and tubes are the invention of Mr. Geo. H. Meeker, and the system is that of Mr. A. Noll, both of the company. The reputation of the company promises that the demand for the Vulcanoid electric wire ducts will fully equal that of the celebrated Grimshaw white core wires, for the company are noted for their persistency in pushing a good thing to success.

The National Electric Co., of Philadelphia, distributed the Warrell fuse block in miniature form.

Lewisohn Bros. were represented by Mr. Rosenstamm in the copper colored suit—somebody wanted to buy him for an ingot. Mr. L. Lewisohn was also present.

The Crocker-Wheeler Motor Co. made a remarkably handsome exhibit in operation of their motors, which on account of their beautiful design, both electrically and mechanically, were commented on by all. The perfection in detail in these machines is most striking. Dr. S. S. Wheeler and Mr. G. W. LaRue were in attendance.

The Clement Mfg. Co., Northampton, Mass., exhibited something first-class and highly novel in the shape of their rubber insulated screwdrivers and plier.

The Weston Electric Instrument Co., of Newark, were represented by Mr. Edward A. Colby. Their famous testing instruments are in universal demand.

The International Okonite Co., of New York and London, Eng., had a double exhibit of attractive style and magnitude. Capt. Willard L. Candee, George T. Manson, H. Durant Cheever and T. McCoubray were all on the spot, and had a good time all round.

The Shultz Belting Co., of St. Louis, were represented by Mr. J. A. J. Shultz, president, and exhibited their noted belting and new pulley covering.

The Johns-Pratt Co., Hartford, Conn., with their vulcabeston insulation, were distributing their paper weight souvenirs. Mr. Edward B. Hatch and Mr. E. B. Williams were present.

"The Electrical Engineer" occupied parlor 7, immediately adjoining the headquarters of the Executive Committee. Besides issuing every day its regular programme of the business before the Convention, the Engineer tried a novel experiment in the shape of a complete registry in its parlor, of all in attendance, the names being posted up on racks as quickly as the arrivals occurred, together with the number of the room occupied by each guest, and other brief information. The registry was in steady use by everybody as a ready reference throughout the Convention, and the stately urbanity presiding behind the Hotel desk characterized the new departure as "a perfect Godsend." The Engineer also had the gratification of publishing the largest electrical paper of the week, namely one of 100 pages and colored supplement. It received innumerable congratulations on the swiftness and sureness with which it had attained this position among a group of technical journals well known for their ability and enterprise.

"The Electrical World" made a bold bid for popularity by a big display and a "full page" style of hospitality. On Wednesday evening, it gave a very delightful and unconventontial "free and easy" in its parlor, with Mr. Johnston as master of the ceremonies, Mr. Fred Royce as guard of the exit, and Mr. Outcault as star raconteur "for this occasion only." The piano was also called into frequent requisition, and was tuned quite often by Mr. G. M. Phelps and other guests. The flow of wit and wine was without parellel at the Convention, and those who participated, could do little else when they met the next afternoon, but exchange languid recollections of an event that deserves place among the Noctes Ambrosianæ of the N. E. L. A. The *World* issued, as usual, its bulletin of the meeting, with wonted fullness and accuracy, due to the painstaking efforts of the indefatigable Caldwell and De Land.

"The Electrical Age" was well represented by its entire New York staff, and made *the* success of the Convention in the souvenir line with its "Aluminum Age" medal. The medal is a very neatly executed one, the size of a dollar ; and as they were bored and had a ribbon attached, everybody wore one. In fact, the good people of Providence got the idea that the medal was the Association badge and treated every wearer accordingly with due honors. It is also said that a great many were paid out as good current coin by waggish and festive "night owls," and were presented later on at the Hotel for redemption. Be this as it may, it is certain that a Convention souvenir was never more of an instantaneous and pleasing success than this, and that the *Electrical Age* deserves a gold medal for its enterprise and originality. The souvenir was moreover extremely appropriate, seeing that it is to progress in the electrical arts that aluminum now owes its position as a useful and readily obtainable metal.

"The Electrical Review" carried off the honors of the Convention floor by its prominence in the Memorial Exercises on Decennial Day. In the absence, through sickness, of Mr. Geo. Worthington, who had been invited to speak, Mr. C. W. Price, the editor of the paper, presented a very interesting historical sketch of the work done by the *Review* in starting the Association. Before the session closed, appropriate action was taken by the passage of a resolution of sympathy with Mr. Worthington in his illness, coupled with hopes for his early recovery and reappearance in active work. At the Hotel, the *Review* occupied one of the large parlors, and received its friends in accustomed manner.

"The "A. B. C." Pole Finder.—One of the hits of the Convention was the neat little book with this suggestive name, issued by Alexander, Barney & Chapin, as a souvenir. It contained a number of sheets of prepared paper for indicating the polarity of a current. The cover was a very pretty one in green and gold.

Thomson-Houston Electric Company exhibited a number of meters for various classes of work. A 1000 volt meter for going on the primary circuit of alternating current circuits was exhibited in operation, and a three-wire direct current meter was also shown working. In another part of the building, a 50 volt meter for secondary alternating circuits was shown, and a 500-volt direct current meter for use on electric railway circuits. A Thomson-Houston motor was also shown operating the exhibit of the New England Butt Company, of Providence.

American Circular Loom Co. showed a very interesting sample of a new flexible conduit for interior work. This conduit is composed of glass beads, surrounded by a strong woven covering, and possesses a number of advantages for interior conduit work. In the exhibit a large glass tube was shown bent in the form of a U and filled with water. The flexible conduit was then strung through the glass tube immersed in the water, and wires carrying current for lights mounted on the board, were inserted in the conduit. The lamps burned all right, showing the high insulating qualities of the conduit, as well as its peculiar adaptability for wiring the inside of houses, no tees, bends or joints of any kind being required. Mr. A. T. Clark represented the company at the Convention.

The Eddy Electric Manufacturing Co., of Windsor, Conn., exhibited two of their well-known 10 horse-power 500 volt motors, and also a ½ and a 1-horse power, 110 volt motor and a 75 light dynamo. The 10 h. p. motors were both used to drive dynamos, one furnishing power to a 100 light Loomis dynamo, and the other driving the 75 light dynamo, mentioned above. The exhibit was well taken care of by Messrs. A. D. Newton and M. E. Baird.

Drake, Payson & Whittier, of Providence, agents for the Eddy motor in Rhode Island, assisted the Eddy Manufacturing Company in showing the motors, and also exhibited the Loomis dynamo, of which they are also agents. A Loomis arc lamp was also shown in operation. They also exhibited two ordinary wooden lamp poles, with Russell mast arms, one showing the top mast arm, and the other showing the side mast arm. Samples of lamp hoods in several styles were also exhibited. Drake, Payson & Whittier are also agents in the East for the Hart snap switch, and the Loomis automatic ground detector. They were well represented by all three members of the firm.

The Jewell Belting Co., of Hartford, had quite an extensive exhibit of their dynamo belting made out of the centres of hides. These belts are becoming universally popular among central station men on account of their first rate qualities. The Jewell Company exhibited everything from the rough leather to the finished belt, and showed a very fine belt 40 inches wide, manufactured for the Toledo Electric Street Railway Company, of Toledo, O., as well as a number of smaller belts. The most interesting part of this exhibit, however, was a sample of a complete butt just as it comes from the tannery, showing a measurement of over five feet of good solid leather which could be used for the belting, and showing how very particular the Jewell Company are in the selection of extra heavy hides for the dynamo belts. The Jewell Company use only the centre of the hides for dynamo belts, no matter how narrow, and one of the best trade marks which they could use, is the mark of the spine of the ox, distinctly traceable down the centre of each belt, manufactured for dynamo purposes. The Jewell Company were ably represented by Messrs. C. E. Newton, C. L. Tolles, E. L. Graves and J. H. Fitzpatrick.

T. M. Foote Regulator Co., of Boston, exhibited one of their 4 horse power patent speed regulators, which attracted considerable attention. Owing to some misunderstanding the regulator was not shown in action, but the principles involved in the construction of the machine were well explained by the representative, with the assistance of several pieces of the mechanism before being put together.

The Holtzer-Cabot Electric Co., of Boston, exhibited only one novelty in operation, their new automatic regulator and pressure indicator.

Albert & J. M. Anderson, of Boston, exhibited samples of the Boston trolley, which is now almost universally used on electric cars, and also a complete line of trolley wire insulators, trolley wire clips, line wire insulators, strain insulators, and other necessaries. Mr. Anderson, himself, carefully explained the merits of his specialties.

The New England Butt Company, of Providence, showed three of their regular type of single and double braiders, and also showed their new machine for covering magnet wire, illustrated in The Electrical Engineer of February 18th. The machines were shown in operation, getting their power from a Thomson-Houston motor installed for the purpose.

The Electric Engineering and Supply Co., of Syracuse, N. Y., exhibited a fine switch-board, with variegated globes and arrangement of lamps, and a full line of wall sockets and Crowell switches for operating the lamps. Fine samples were also shown of station switches, double pole and double throw, E. S. rosettes, key sockets for all systems, fixture spurs, plain and clamp, fixture cut-outs and ceiling rosettes without fuses. They showed also an automatic clock for extinguishing incandescent lights at any predetermined time, and also a full line of specialties for line work, and electric railroad supplies. The exhibit was in charge of Messrs. F. H. Leonard, Jr., J. L. Hinds and Percy A. Clisdell.

The Munsie Coles Subway Co., of New York, were represented by Mr. Thos. L. Coles, Jr., who showed a number of drawings of his subway and interior conduit.

The Bernstein Electric Co. exhibited a number of their series incandescent lamps and fittings, and made a special exhibit of their new current and potential meters which can be used either on direct or alternating circuits. These instruments are absolutely accurate, have no iron or steel in their construction, and are portable, possessing very little weight. Though but recently introduced, the demand for them is already unprecedented. Mr. H. B. Cram and Mr. W. C. Fish, attended the Convention and looked after the exhibit.

The Standard Electric Co., of Vermont, were represented by Mr. F. M. Ferrin.

The Parker-Russell Mining & Manufacturing Co., St. Louis, the well-known manufacturers of "Sunlight" carbons were ably represented by Mr. D. R. Russell, who held his end up in the most approved fashion. Mr. Parker was also present.

Mr. Clarence E. Stump was present with his associate of the *Street Railway Journal*, Mr. J. H. McGraw, and was received by everybody with a welcome that would probably have carried a less modest and self-possessed man clean off his feet. While many who had not seen him since his release from an irksome and thankless task, expressed their regrets that he had to a certain extent ceased to be an electrical man, they did not fail to congratulate him heartily on his connection with so admirable a paper as the *Journal* and upon the fact that in most respects he was still "one of us." Mr. Stump had the pleasure of introducing Mr. J. H. McGraw all around, and between them the whole field of Convention work and acquaintance was well covered.

Mr. E. V. Cavell, though far from well, showed the growing reach of electric light and power interests by coming all the way from Chicago to represent the *Street Railway Gazette*. His enterprise had its reward.

The C. McIntire Company, of Newark, N. J., were represented by Mr. McIntire, who had a full line of samples of his invaluable connecters with him on exhibition.

Jas. W. Queen & Co., Philadelphia, had a most extensive exhibit of their well-known testing instruments of all kinds and were represented by Mr. E. G. Willyoung.

The Crosby Electric Co., New York, showed their batteries, which are noted for their many excellent qualities. Mr. L. Walsh was in charge.

The Perkins Electric Switch Mfg. Co. had a most comprehensive exhibit of their switches, lamps, etc., which attracted its full quota of attention. Mr. E. W. Davis looked after the company's interests.

The National Electric Manufacturing Co., of Eau Claire, Wis., exhibited their excellent alternating system and the Hon. Geo. B. Shaw, general manager, was on hand to explain its salient and advantageous features. Mr. Latshaw was also in attendance.

The Connecticut Motor Co., of Plantville, Conn., showed their machines in operation. Their many merits and beautiful mechanical workmanship called forth numerous tokens of commendation.

A. N. Baeder & Co., Providence, showed their new metallic cable support.

The Consolidated Fruit Jar Co., of New Brunswick, N. J., had their specialties, fuse wire, &c., on exhibition in charge of Mr. F. P. Wisner.

Pass & Seymour, of Syracuse, N. Y., exhibited a number of their specialties in China goods for electrical work, embracing circuit breakers, rosettes, cleats, bases for switches, sockets, etc. They claim that these China goods are much stronger than those of porcelain and not at all brittle, and screw threads can readily be moulded in the material. Mr. A. P. Seymour, who looked after the interests of his company, showed also his improved carbon holders for arc lamps.

H. T. Paiste, of Philadelphia, had a handsome board on exhibition with a large variety of his well-known switches bearing his name. Particular attention was given to these switches, made of material which is specially designed for use in rooms where something ornamental as well as useful is required, and some very beautiful colors and designs were displayed.

O. S. Platt, of Bridgeport, showed a complete line of his well-known switch, and attended to the inquiries of his numerous friends and patrons in person.

The Walker Electric Co., of New York, showed their new recording meter and ammeters in operation, and Mr. G. W. Walker explained the inside workings of the machines to hosts of enquirers.

The Standard Electric Supply Company, of Boston, showed a complete line of Platt switches and Hill switches, but made a special display of the Standard measuring instruments for which they are exclusive agents. They also showed a sample case of wires and cables manufactured by J. A. Roebling's Sons' Co., of Trenton, N. J. and samples of their screw drivers with insulated handles. Mr. W. A. Stowe officiated for the Standard Company in his usual engaging manner.

The Pettingell-Andrews Co., of Boston, the New England specialists in Okonite and "K. W." goods, made a handsome display of wires, cables, cut outs, rosettes, P. A. rosettes, and in fact showed samples of almost everything required in the electric light and railway business. A reflector for the headlight of a car, was one of their most novel exhibits. Mr. F. E. Pettingell, Mr. D. A. Andrews, Mr. C. W. Price and Mr. Levi Cofren represented them at the Convention.

Gould and Watson Co., of Boston, the well-known manufacturers of moulded mica specialties, exhibited a full line of electric railway insulators, and all kinds of appliances insulated with their material. They showed an incandescent lamp fitted on one of their new waterproof sockets burning in a glass jar of water, to prove their claims to waterproofness. A full line of screw drivers manufactured by the Clement Manufacturing Company, of Northampton, Mass., and insulated by moulded mica, was also shown. Mr. E. P. Sharpe, of Boston, was in charge of the exhibit, and Mr. C. Tennant Lee was also in occasional attendance.

The American Electric Works, of Providence, showed very beautifully finished samples of everything in the shape of insulated wire, from the finest grades of magnet and annunciator wire up to large lead covered telephone cables. Flexible cord was also in abundance, and the exhibit with the reels of line wire, surmounted by coils of variegated hue of office wire, made a very attractive appearance.

The Standard Underground Cable Co., of Pittsburgh, showed some very handsome samples of their well-known underground wires and cables, and wires for aerial use. They also had a number of their No. 11 handbook for distribution, on which there was a great run, it being a perfect mine of information to the Electrical Engineer. Mr. J. W. Marsh and Mr. T. F. O'Connor were in attendance.

The B. & S. Electric Equipment Co., represented by Mr. N. Bushnell, showed a few samples of the B. & S. special "roxite" ceiling cut-out, which is perfectly acid, water, and fire-proof.

A. W. Harris Oil Co., of Providence, showed a number of samples of their oils specially manufactured for engine, valve and dynamo use. Neat little sample cases of the oils were freely given away.

The exhibits, beyond those in the hotel, were grouped in Union Hall, where, under the able direction of Gen. C. H. Barney and Mr. W. J. Hammer, a large and beautiful display was made. The Exhibition was opened with electrical honors on Tuesday evening, by the young daughter of Supt. Thomas, of the Narragansett Electric Light Co., of Providence. The Exhibition was visited by thousands of persons.

THE NEW ELECTRIC MERCHANDISE CATALOGUE.

The Electric Merchandise Company, of Adams street, Chicago, have issued their mammoth new catalogue of electric railway supplies, to which line, as is well known, they devote their entire attention.

The book is most complete in every detail and will be found of the utmost utility to every street railway man, who should not fail to secure a copy immediately, and they will find it of unsurpassed value. It is very handsomely and uniquely gotten up throughout, being replete with handsome cuts and comprehensive descriptive matter of every article. Many new new specialties of striking novelty and advantage are embodied in it. Measuring and testing instruments, regulating station apparatus, lightning arresters, switches, incandescent lamps, sockets and fittings, cut-outs, fixtures and fuse wires, insulating material, headlights, gongs, electric heaters, poles, trolleys and trolley wire insulators, centre curve insulators, pull-over brackets, wire, line construction tools, and all the other detailed portions of apparatus which go to make up the complete electric street railway. The new Brewster trolley hanger is of special interest and will probably be known as the "Scissors" trolley hanger. It works on that old-time and highly effective principle. The catalogue is replete with many valuable points on construction work, and is one of the most complete, desirable and best ever brought out.

W. F. Wheeler, electrician for The Equitable Life Insurance Company, is still in St. Louis, fitting up the company's building in that place, with electric apparatus.

TRADE NOTES AND NOVELTIES

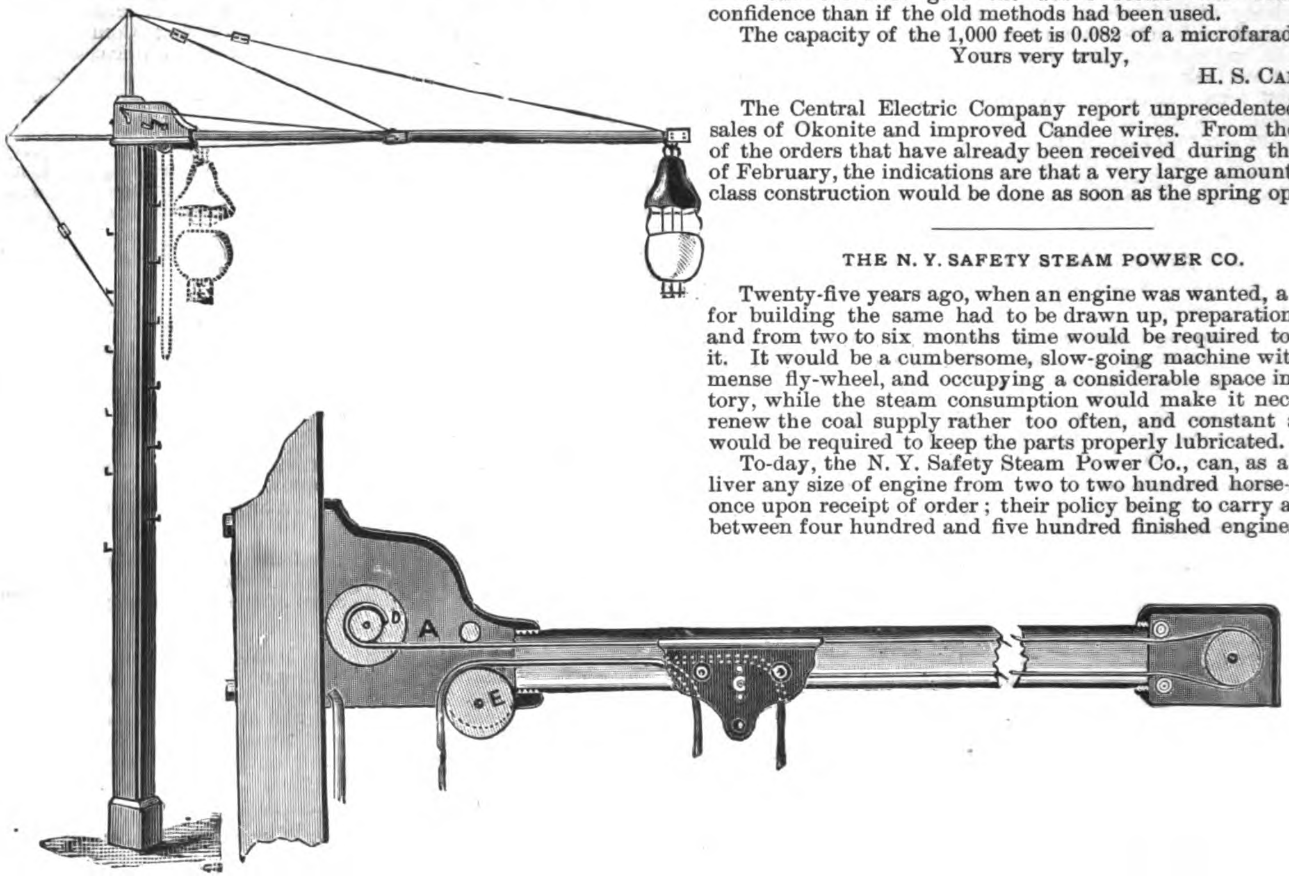
AND MECHANICAL DEPARTMENT.

"He who advertises boldly has faith in himself, in his goods and in the public."

THE RUSSELL MAST ARM.

THE accompanying illustrations, Figs. 1 and 2, represent a mast arm for suspending arc lamps over streets, public squares, etc., made by the Russell Electrical Manufacturing Company, of Providence, R. I. As will be seen, the arm is fixed, and the lamp is drawn to and from the pole by means of pulleys encased in a hollow cylinder. The arm may be attached to the top of the pole, as shown in Fig. 1, or to the side.

Fig. 2 is a lateral section of the arm, showing the carriage C the cord A and the drum D by means of which the lamp is drawn out over the street. The electric cable itself, passing over the drum E, is used to draw the lamp to the pole.



FIGS. 1 AND 2.—THE RUSSELL MAST ARM FOR SUSPENDING ARC LAMPS.

There are no visible electric wires, and all the mechanism is encased so as to be absolutely protected from snow and ice. The arms may be of any length, and by means of suspending cables, lamps may be carried into the centres of the largest public squares.

The longest arm now in use is 42 feet, and the shortest five feet. The main parts are made of extra heavy lap-weld steam pipe, the rods of either steel or the best Norway iron, and the working parts and fittings are all interchangeable, and are case hardened to prevent wear. The electric conductors are made especially for this arm by the American Electrical Works.

These arms are in use in 40 cities and towns throughout the country, and were favorably commented upon by the members of the National Electric Light Association at Providence.

THE CAMBRIDGE ACCUMULATOR is the property of the Cambridge Accumulator Company, of Boston, of which Mr. Matthew Clark is president, and Mr. Wm. A. Macleod is attorney, to whom all communications should be addressed at 62 Devonshire street, Boston, Mass. The cell is the invention of Mr. George E. Hatch, of Cambridge, Mass., who has been at work on it for about two years. It is fully covered by United States and foreign patents.

A TEST OF OKONITE.

The Central Electric Company has just received the following letter:

UNIVERSITY OF MICHIGAN, ANN ARBOR,
Feb. 12, 1891.

Physics aud Electrical Engineering.

MR. F. W. CUSHING,
Sec., Central Electric Co.,
Chicago, Ill.

Dear Sir: Some time in the latter part of 1887, the Central Electric Company sent me a coil of 1,000 ft. No. 18 B. W. G. braided Okonite wire, to be used in measuring insulation resistance. For more than six months of the time since, it has been under water in a tank. Its insulation resistance has increased, rather than the reverse.

At present, it measures 16,100 *megohms per mile* at a temperature of 17° C.

Mr. Patterson, instructor in physics in my laboratory, has devised a new and improved method of measurement, by which the percentage of error is much reduced.

I can therefore give the above result with much more confidence than if the old methods had been used.

The capacity of the 1,000 feet is 0.082 of a microfarad.

Yours very truly,
H. S. CARHART.

The Central Electric Company report unprecedentedly large sales of Okonite and improved Candee wires. From the nature of the orders that have already been received during the month of February, the indications are that a very large amount of high-class construction would be done as soon as the spring opens.

THE N. Y. SAFETY STEAM POWER CO.

Twenty-five years ago, when an engine was wanted, a contract for building the same had to be drawn up, preparations made, and from two to six months time would be required to produce it. It would be a cumbersome, slow-going machine with an immense fly-wheel, and occupying a considerable space in the factory, while the steam consumption would make it necessary to renew the coal supply rather too often, and constant attention would be required to keep the parts properly lubricated.

To-day, the N. Y. Safety Steam Power Co., can, as a rule, deliver any size of engine from two to two hundred horse-power at once upon receipt of order; their policy being to carry a stock of between four hundred and five hundred finished engines. Their engines are compact and substantial, quick-running machines, occupying little room (a 100 h. p. engine requiring but 9½ feet by 6½ feet floor space over all), noiseless in operation, fitted with automatic sight feed lubricators on every journal and pin, and requiring but half as much steam as the old style engine. They guarantee a coal consumption of between 2½ and 3 lbs. per horse power per hour for their single cylinder engines, while their compound engines show less than 2 lbs.

The class of engines referred to above are of the self-contained automatic cut-off type, and they possess advantages which recommend them highly for all industries where power is required, but more especially for electric light service, for the reason that direct connection may be made with dynamos and the most perfect regulation attained. For this reason it was thought best to employ them in the *World* building, N. Y., where they have given excellent satisfaction.

The engines are built on the system of duplication of parts, whereby, in the event of accident, a new part that will fit accurately may be obtained from the company's store at No. 30 Cortlandt street, at once upon receipt of order.

The promptness with which the N. Y. Safety Steam Power Co. can execute a contract is strongly illustrated by the following facts. A little more than a year ago, a prominent electric light company, who were using a number of these engines, met with a disastrous fire in which all the engines in their station were destroyed. An order was placed with the Power Co. for three engines aggregating six hundred horse power, and in nine days after the receipt of the order these engines were in full operation and have been running steadily ever since without a hitch. Pending the installation of this plant, three 150 h. p. Safety engines took this heavy load for the nine days without developing an overheated journal, or showing distress of any kind.

THE "H. C." PRESSURE INDICATOR AND REGULATOR.

THIS instrument, as shown in the illustration, Fig. 1, consists of a solenoid through the centre of which an armature composed of a bundle of soft iron wires moves, and is controlled by the attraction of the solenoid opposed by the force of gravity. In this way, the instrument, once set, will remain constant for an indefinite period, it not being dependent on springs whose power may change.

This instrument is arranged in connection with a circuit closing device so that when the E. M. F. rises above the standard at which the instrument is set a red danger lamp is lighted. If the E. M. F. falls below the standard a green lamp is lighted. When the pressure remains constant neither lamp burns. The object of this is obvious as the attention of the dynamo tender is called by the burning of either lamp and he can see at a glance whether the pressure is too high or too low and apply the proper remedy. The hard rubber plate carrying the solenoid and circuit closer is made to rotate upon the base so that the instrument can be set for any E. M. F. with a standard voltmeter.

An automatic device, Fig. 2, is supplied which can be used in connection with the indicator and operated by it, which, when driven either by a pulley and belt from a shaft or by an ⅛ h. p. motor, automatically throws in or out resistance, so as to bring back the normal pressure, thereby making it possible to keep the pressure constant on long feeders calculated to work under a high percentage of loss. The above apparatus is particularly designed for use in controlling the E. M. F. of a dynamo or the pressure at the lamps when run from a storage battery. This instrument is made by the Holtzer-Cabot Co., of Boston.

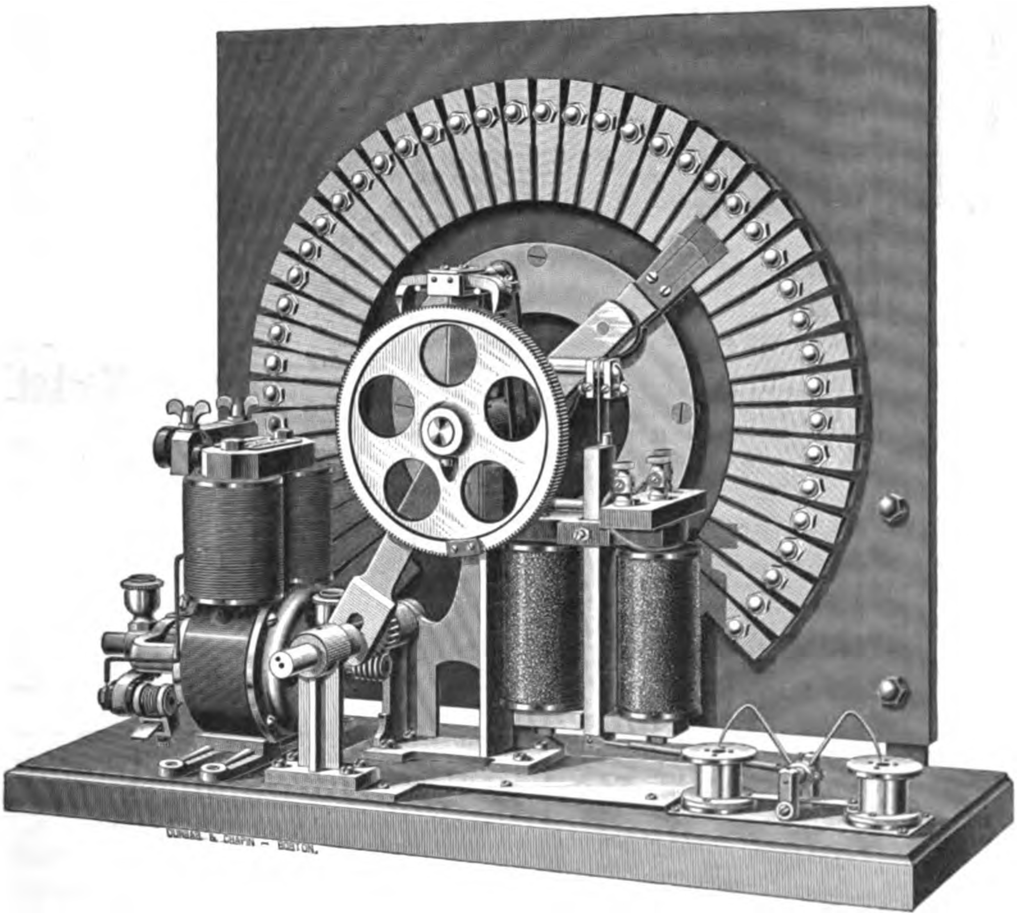


FIG. 2.—THE "H. C." AUTOMATIC PRESSURE REGULATOR FOR CONSTANT POTENTIAL CIRCUITS.

MR. DAVID PERCY, formerly engineer of the electric light plant at Scottdale, Pa., has accepted a position with the Novelty Manufacturing Company, of Allegheny City.

MR. W. L. ARNOLD, agent of the Thomson-Houston Electric Co., has secured contracts for 600 lights for the north and south end power stations of the St. Louis Cable Railroad and a 20 h. p. Thomson-Houston Motor for the Osage Mining Co., McAllister, I. T.

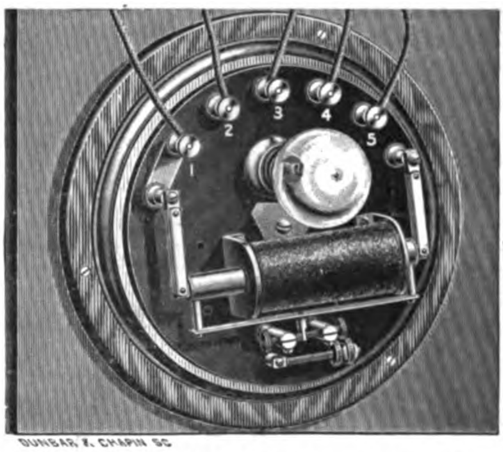

FIG. 1.—THE "H. C." PRESSURE INDICATOR.

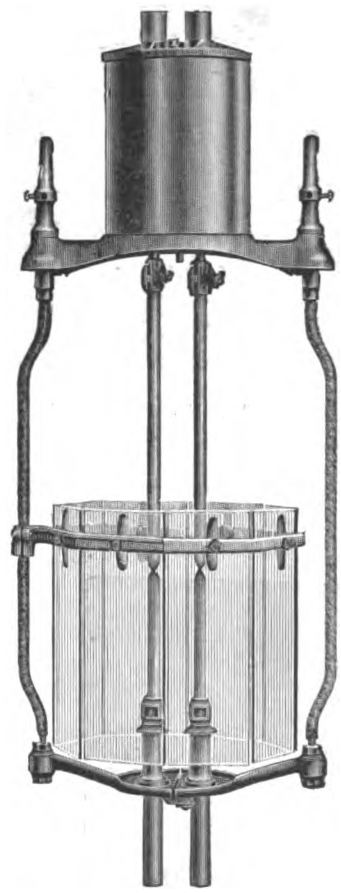
BOSTON, MASS.—Michael Creed has brought suit against Minot J. Kendall and others, to recover $10,000 damages. On July 17th, 1889, the defendants were engaged in putting up electric light poles, and had dug holes for the purpose, when a four-year old child of the plaintiff fell into one of the holes, receiving injuries which resulted in death on September 21st. This, the plaintiff asserts, was due to negligence on the part of the defendants.

The defence is a general denial.

FORT WAYNE, IND.—The suit recently brought by the Fort Wayne "Jenney" Electric Light Co. against Abner Crossman, Samuel and Simon Heavenrich, Louis Mendelssohn, Hugo Hill, Isaac Mendelssohn and Sigmund Simon, to recover on a broken contract said to have been entered into for the construction of storage batteries, has been discontinued in the Wayne circuit court.

THE GWYNN GLOBE FOR ARC LAMPS.

THE accompanying cut illustrates the Gwynn globe, which is being put on the market by the Western Electric Company, of Chicago, and New York. This globe possesses many points of superiority. It is made up of eight pieces of heavy French plate glass, securely bolted to a brass collar, which, in turn, is bolted to one side of the lamp. Being open at the top and bottom, it allows of carboning the lamp without removing the globe, and also prevents the accumulation of dirt and insects. If any plate is broken it can easily be replaced, without removing the globe from the lamp.

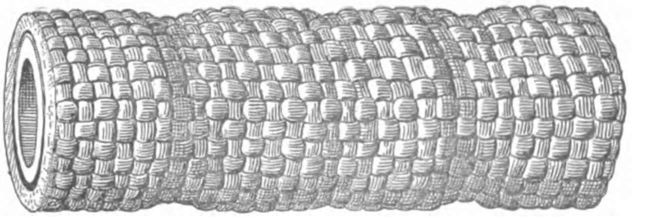


THE GWYNN GLOBE FOR ARC LAMPS.

A NEW FLEXIBLE GLASS INTERIOR CONDUIT.

WITHIN the last few years the subject of interior conduits for electric conductors has deservedly engrossed the attention of electrical engineers.

The much desired qualities in such a conduit are flexibility, insulation, and ability to resist fire, the first of these being a matter of the utmost importance, bearing directly on the cost of installation, and saving a large amount of labor. It also allows the installation of a conduit in old buildings without cutting the walls for the whole distance. The best insulator in use is glass, and if a conduit can be made of glass, and still be both waterproof and flexible, the desired end is, it is claimed, reached at once.



WRIGHT'S FLEXIBLE GLASS INTERIOR CONDUIT.

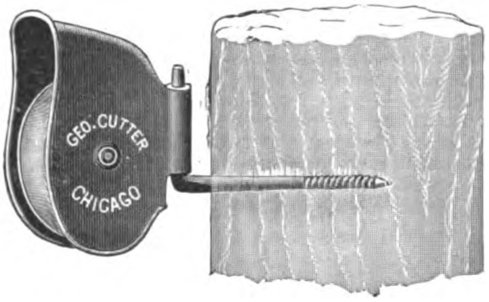
After much study, and many experiments, Mr. Alex. P. Wright, of Boston, has produced a flexible glass tube, which is said to be perfectly waterproof, and practically fireproof. It is shown in the accompanying illustration. The conduit is enclosed in a strong woven jacket, which gives it a high tensile strength, and a strong abrasion resistance, and the whole is then soaked in an insulating material. The system of connections is simple, and the cost for this item is quite small.

The American Circular Loom Co., of 620 Atlantic avenue, Boston, have undertaken the manufacture of this new conduit, which was exhibited at the Electrical Exhibition, at Providence during the Convention. There a section of it was shown connected with a lighting circuit and passing through a glass tube filled with water and bent twice at right angles in a sharp curve, thus showing the great flexibility and waterproof qualities of the conduit.

THE MORRIS SWIVEL POLE-PULLEY.

A LARGE percentage of the arc lamps used for outdoor lighting is hung from a cord passing over a pulley, and their safety must depend on the strength of this cord. Usually there is another pulley fastened to the pole, and the cord passes over this pole-pulley down to a cleat or windlass. Such a pole-pulley is, it is said, rarely found to be in line with the cord, and the result is that the rope scrapes on the edge of the pulley and wears out in a short time.

As a simple remedy for this chafing of the cord, Mr. E. P. Morris has designed a pole-pulley. As the cut shows, it is a sleet proof pulley which fits the upturned end of an ordinary pole-step and which can swing freely on this support. It is evident that such a pulley is quickly put up and will always stay in line with the cord. It can also be used as a wall-pulley, and other uses will suggest themselves to those who have found an ordinary pulley too rigid for many purposes. It is about to be put on the market by George Cutter, the "electrical specialist," of Chicago, who is also maker of the various electric railway specialties designed by Mr. Morris.



THE MORRIS SWIVEL POLE-PULLEY.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of Feb. 21, 1891, from New York, Boston and Washington; Pittsburgh, Feb. 21.

THE
Electrical Engineer.

VOL. XI. MARCH 4, 1891. No. 148.

PATTEN'S NEW ALTERNATING MOTOR.

AMONG the many ingenious arrangements for operating alternate current apparatus, devised by Mr. F. Jarvis Patten, our readers will recall one in which a three-wire system is employed. In this the outer circuits transmit, respectively, positive and negative impulses, while the neutral wire constitutes the return circuit for both. Recently, Mr. Patten has applied this system to a novel type of motor, which is shown diagrammatically in the accompanying engravings. These show, respectively, two successive positions of the armature, being in other respects identical.

The motor has two independent armature windings, each having its own commutator. There are also two separate field magnet circuits, and the circuits of each machine are so arranged that each receives the current in turn, while the other is cut out. A^1 and A^2 are the two independent Gramme rings, and F^1 and F^2, their independent magnetic circuits, respectively. The commutators are arranged in alternate groups of segments, the odd numbered groups, 1, 3, 5, 7, in each, being subdivided into segments connected to the ring winding in the ordinary way. The intermediate portions, 2, 4, 6, 8, are uncut, and all connected together as one. The brushes resting on both commutators are so arranged that their points bear upon the same line, parallel with the spindle to which both armatures are secured. From this it is evident that when the brushes bear upon the connected segments of one commutator, they bear also upon the intermediate, disconnected, segments of the other, so that one armature is short circuited, while the other is operative, and *vice versa.*

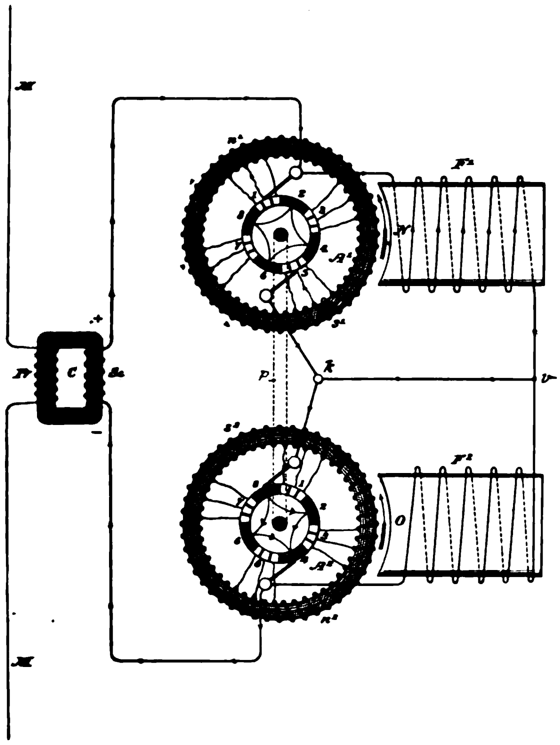

FIG. 1.—PATTEN'S NEW ALTERNATING CURRENT MOTOR.

It will be seen from Fig. 1, that the armature A^1 and its field F^1, are momentarily operated under the action of the positive current in the ordinary way, and whether the current be alternating or not, the tendency to rotation in the upper armature with respect to its field-magnet F^1 will be in the direction of the arrow, as shown, and motion will ensue. As the armatures turn upon the common spindle, shown dotted, they are eventually brought to the position shown in Fig. 2, in which the upper machine, having its brushes on the disconnected segments, is now cut out of circuit and is not operative, while the lower machine has come into a position where both its circuits, field and armature are in operation. This corresponds to the time period of a negative impulse, and these two phases of current, indicated in Fig. 1 by the single arrows and in Fig. 2 by the double arrows, indicating a reversed current, operate the two parts successively, one field and armature being operative, while the other, for the time being, is cut out of circuit, and each, for the time being, acts as an independent direct-current machine.

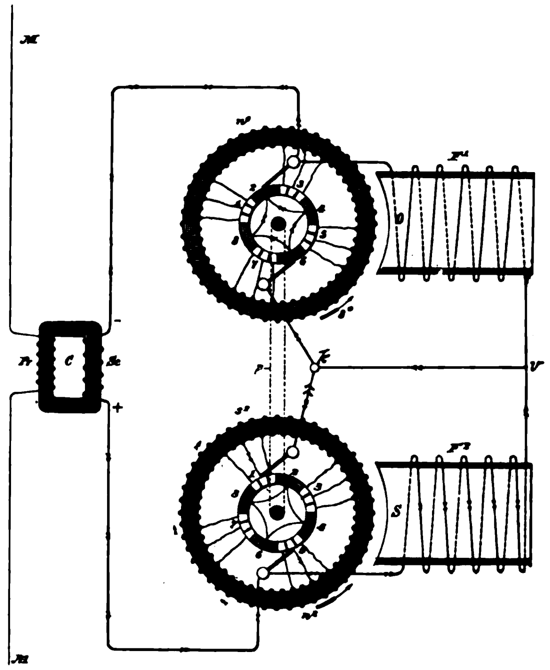

FIG. 2.—PATTEN'S NEW ALTERNATING CURRENT MOTOR.

The wire from K to V, common to both field-magnet circuits in shunt relation to their respective armatures, is one of the essential features of this system of motor-circuits. It amounts, in fact, to an application of the divided three-wire system of Mr. Patten, to the internal circuits of a motor. The armatures are connected in series relation to each other, the fields in shunt relation to their respective armatures, and each in turn made operative as the other is short-circuited. It will be seen upon examination of the circuits, that the converter secondary S C is therefore always working through the same resistance, as each machine, in turn, is cut into its circuit, while the field-magnets, after synchronous motion has been obtained, keep a constant polarity, by reason of the fact that each in turn gets a succession of positive or negative impulses, and the same holds true of the armature circuits.

THE BEACON VACUUM PUMP FOR EXHAUSTING INCANDESCENT LAMPS.

In the manufacture of incandescent lamps it is a question of the greatest interest whether non-mercurial, metallic pumps will supersede the present well-known forms in which glass and mercury are used for the production of vacua in the lamp globes. While the mercurial pumps produce excellent results when properly used, they labor under many disadvantages, among which may be mentioned the following: Extreme slowness of operation, lack of uniformity in results, the necessary investment of large amount of capital, great cost of maintenance, ill effects upon the health of the operators, and the requirement of a large amount of floor space. Nevertheless, until recently, it is only these pumps which have been found capable of producing the fineness of work required in the manufacture of incandescent lamps. The problem of producing a non-mercurial pump capable of attaining the necessary perfection in its work has been surrounded with so many difficulties, that nearly all who have given the subject attention have come to believe that the problem was practically unsolvable; very few, therefore, who were capable of dealing with so difficult a subject have given their best endeavors to it. Consequently, this field for invention has, until quite recently, been barren of results.

An ordinary knowledge of mechanics was not sufficient, evidently, to solve this problem, as the inventor was at once met by such difficulties as were offered by the porosity of metals, the impossibility of making mechanical joints and moving surfaces perfectly air-tight, as well as the difficulty of expelling all the air from the pump cylinder at every stroke of the piston, and many other difficulties too numerous to mention.

In order to counteract the porosity of the metals used in the construction of a non-mercurial metallic pump, and to render the joints and moving surfaces perfectly air-tight, it is necessary to use a sealing liquid of some kind. It is quite evident, that in order to answer its purpose, this liquid should possess certain unusual and indispensable qualifications. For instance, it must be non-corrosive, it must possess no volatile constituents, and must be a lubricator. Among the liquids furnished by nature and by the laboratory there are very few, indeed, which are not volatile to a very considerable extent. Those which are most nearly non-volatile, and which, at the same time, are non-corrosive and also lubricators, are confined principally to that class comprising the fixed oils, either animal or vegetable. But even these, in the form in which they occur, contain a greater or less amount of volatile impurities which must be eliminated, and different oils properly compounded before a liquid is obtained suitable for use in a pump for high vacua.

Furthermore, all these fixed oils absorb and carry with them a considerable amount of air and other gases. If this absorbed air is removed these liquids will, on again coming in contact with the air, re-absorb it; so that, in order to use them in high vacuum pumping, they must not only be freed from absorbed air, but must be continually kept in a deaerated state. When deaerated oil is exposed to air, though under but slight pressure, only a few seconds are necessary for so much absorption to take place that a fine vacuum would be lost by the introduction of a small quantity only of such oil into it. From this it is obvious that unless a non-mercurial metallic vacuum pump is sealed both inside and outside by a non-volatile and thoroughly deaerated liquid, no hope of success can be entertained. Mercury, it is true, does not absorb air to an appreciable extent, but it cannot be used as a sealing medium for metallic pumps, for the reason that it is not a lubricator and will amalgamate even with steel and iron under the conditions in which it exists in the cylinder of a vacuum pump, and further, it does make an air-tight joint with a metal, as it does with glass. This has been demonstrated by expensive experiments. Neither can mercury be used in combination with oil, as they form a paste when agitated together. It is not our intention here to follow through all the experimental stages leading up to a knowledge of the principles already set forth, but we will at once proceed to describe the "Beacon" vacuum pump, which, we may safely state, is the embodiment of a comprehensive understanding of the foregoing principles among many others.

We cannot at present give our readers an exact drawing of the precise form and details of the pump as it is built to-day by the Beacon Vacuum Pump and Electrical Company, of Boston, but will consider some of its most important elements which have been recently patented and which are illustrated diagrammatically in the accompanying engravings.

The method of jacketing or outside sealing of the vacuum pump by deaerated oil or other liquid, a most important feature, is shown in Fig. 1. Here A represents the inner cylinder of a vacuum pump, and A^1 the jacketing cylinder. The space S between the two cylinders is closed at all points so that no air can enter it. B represents the bottom of the cylinder proper, and B^1 the bottom of the jacketing cylinder.

The valves used consist of a valve D, serving to admit air from the chamber being exhausted; and of a second valve E, through which the air is to be expelled. The above described valves are not operated by the pressure of the air, but are provided with mechanism which causes them to act independently of the air, and at such times as the best action of the pump requires.

M is a reservoir for oil located above the spaces in and about the pump, so that the oil will flow by its gravity, unless checked, from the reservoir to the spaces to be sealed. This reservoir is connected by the pipe K^2 to a force pump K^1, and through the force pump by the pipe K to the jacketing spaces S, S^1, S^2 of the vacuum pump. The circulation of the oil being completed through the pipe L, weighted valve L^1 and pipe L^2.

In the illustration an auxiliary air-pump M^1 is shown immediately over the oil reservoir.

The mode of operation is as follows: The oil is placed in the reservoir M, thence made to fill the circulation pipes and spaces S, S^1, S^2, of the vacuum pump to be sealed. Now if the apparatus be started, the oil in the reservoir M, will be subjected to a vacuum and its embodied air will expand and rapidly leave it in a deaerated condition; as the movements go on, all of the oil in the circulation pipe and in the sealing parts will become deaerated to such a degree that no more air can be drawn from the oil, and thus the oil becomes a medium properly adapted for the purpose of sealing. If the oil in its circulation becomes, from any cause, re-aerated, as it readily absorbs air when brought in contact with it, it is again restored to its airless condition by the continued action of the vacuum in reservoir M.

The reason why the sealing or jacketing liquid in a vacuum pump must be deaerated, in order to secure success, is, as alluded to above, that if not so treated, in its gradual leakage through the walls and joints and past the moving parts of the pump, it would carry with it its absorbed air and give it out on the interior, thereby rendering the attainment of a high vacuum impossible.

We now come to the method employed of completely expelling the air from the cylinder at each stroke of the piston, the principle of which is shown in Fig. 2.

It is not a new thing to introduce a liquid into the cylinder of an air pump for the purpose of expelling the air at the termination of each stroke. Several of the large steam air pump manufacturers have used water for this purpose; but their pumps were not designed for high vacua. In pumps for the latter class of work it is essential that the air should be completely expelled from the cylinder at the end of each stroke. To accomplish this result a liquid must be used to fill the interstices under and about the piston, thereby expelling all the air. This, as shown in Fig. 2, is accomplished by forcing at each upward stroke of the piston, a quantity of the deaerated oil into the cylinder, which serves to fill all of the unoccupied space under and about the piston when it is at its lowest point, thus expelling all air; during the downward stroke of the piston all excess of oil is forced out of the cylinder into a vacuum tank, in which tank the air that has been taken up by the oil during the descent of the piston will be withdrawn, and the oil will be ready to be again forced (in its deaerated condition) back into the cylinder, from which its excess is again expelled and returned to the deaerating tank, this circulation and deaeration taking place at each stroke of the piston.

An ingenious method of making an air-tight connection between the leading pipe of the vacuum pump and the glass stems or forks by which the lamps are attached for exhaustion, is shown in Fig. 3

The Beacon pump is intended to exhaust a large number of lamps at one operation, and the question naturally arose, What will become of all these lamps if a globe should break or a sudden leak occur while they are burning on the pump and the filaments are at incandescence? The answer to this question was obvious. They would be destroyed before the hand of the operator could shut off the current. To overcome this difficulty the simple arrangement shown in Fig. 4 is employed. By it an influx of air into the vacuum system, even if very slight, opens or closes, as the case may be, through a mercurial manometer, a secondary circuit, which, operating through an electro-magnet, instantly cuts off the main current from the lamps. The operation of this device would require but a small fraction of a second and by it the danger of injuring a large number of filaments by an inadvertent break is eliminated.

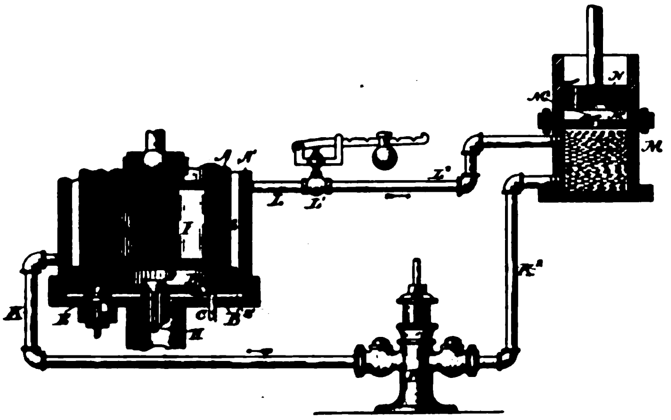

Fig. 1.—The Beacon Vacuum Pump.

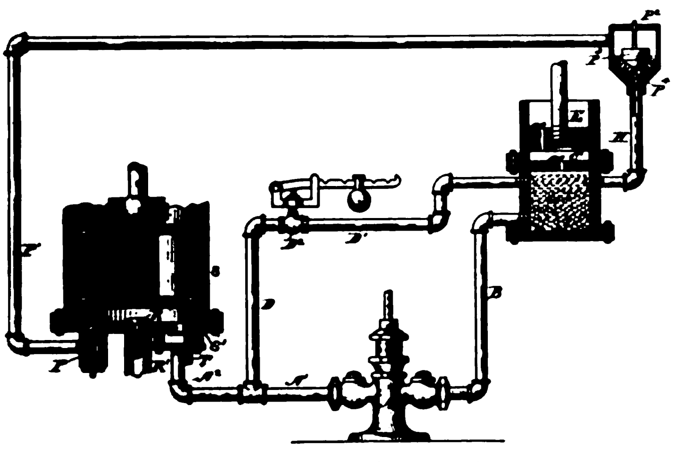

Fig. 2.—The Beacon Vacuum Pump.

Incandescent lamps exhausted on the Beacon non-mercurial pump are claimed to have some characteristics which distinguish them from those made by the mercurial process. These two kinds of lamps do not answer all tests alike. One reason for this may be explained as follows: By no process of exhaustion is the vacuum absolutely perfect. Attenuated vapor or gas of some kind always remains. With lamps exhausted by the mercurial apparatus this attenuated remainder consists of air and mercurial vapor. In those lamps exhausted upon the Beacon pump it consists of air and a certain amount of hydro-carbon vapor derived from the oil used in the pump. It is quite natural to suppose that these two kinds of lamps should respond somewhat differently to the different tests to which they are subjected. For example, what is known as the induction coil or spark test shows more color in lamps from the Beacon pump than is given by the best specimens of mercurial work. However, it is only the best specimens of mercurial work which are able to make a better showing by this test. But it should not be assumed from this that the mercurial lamps have a better vacuum, simply because they may show a trifle less color by the spark test, since the two kinds of lamps contain vapors of a different quality. This reservation of opinion is justified by the fact that, when carefully opened, under clean, dry mercury, the remaining bubble of air is smaller in the lamps from the metallic pump than in those from the mercurial pumps, except, perhaps in an occasional specimen of super-excellent mercurial work.

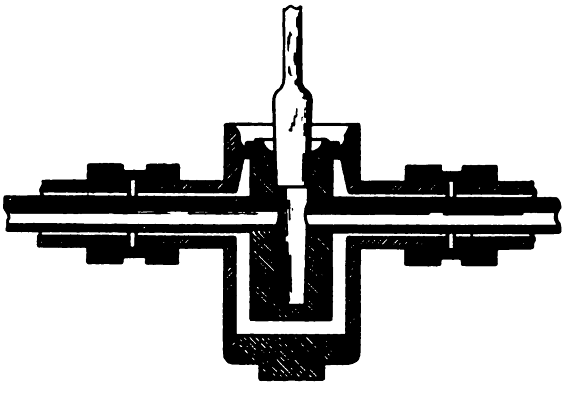

Fig. 3.—Joint of Beacon Vacuum Pump.

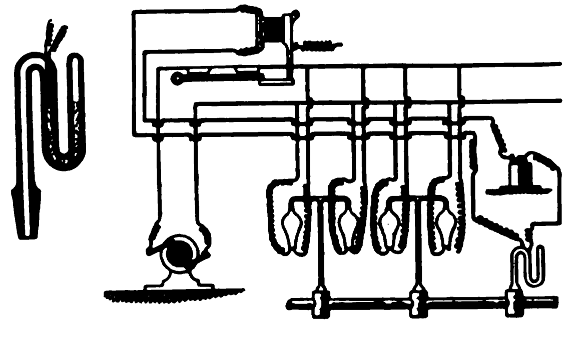

Fig. 4.—The Beacon Vacuum Pump.

Nor is this said to be the only testimony in favor of the excellence of the results obtained by the mechanical oil-sealed pump, since numberless experiments have shown that the vacuum in a lamp from the Beacon form of pump improves more rapidly on burning the lamp (leaks excepted) than in that of a mercurial origin. The experiments referred to were to open carefully, under mercury, lamps of both mercurial and metallic pump origin, which had burned from a few hours up to many hundred. Hundreds of these lamps have been so tested, and the fact brought out that whereas the mercurial lamp, after burning a considerable time, showed an average of less residual air than new lamps of the same make, lamps from the metallic pump under the same conditions showed either microscopical amounts of air remaining, or, as was very often the case, filled so completely that no residue could be observed.

Still another test by which the non-mercurial lamps are claimed to have shown their superiority is their ability to endure over-voltage. Many experiments have been tried in which lamps, some of which were exhausted mercurially and some by the metallic pump, the filaments and other portions of the lamps being of the same make, were burned above their normal voltage and intended candle power. In these tests the lamps having the non-mercurial vacuum have almost invariably out-burned their rivals. This superiority and peculiar action of the non-mercurial vacuum is attributed to the probable decomposition of the hydrocarbon vapor of the oil, its carbon depositing upon the heated filaments and the small residue of hydrogen disappearing in some way unknown. The question of the quantity of work that can be accomplished by means of the Beacon pump depends merely upon the size of the machine, which, in contradistinction to the mercurial pump, can be built of any proportions desired.

The inventors who have produced this successful pump are Mr. Adolph Berrenberg, of Somerville, and Mr. William E. Nickerson, of Cambridge, Mass. Mr. Berrenberg was the first in this connection to entertain the idea that a metallic vacuum pump could be built suitable for incandescent lamp work, and pursued his experiments for several years.

Mr. Nickerson, who is a graduate of the Massachusetts Institute of Technology, became associated in the enterprise about a year ago, and since that time many improvements have been added and many experiments performed. The Beacon Vacuum Pump Co. have a large and well-equipped factory in Boston for manufacturing their pumps and are also carrying on considerable experimental work upon incandescent lamps.

A NEW STORAGE BATTERY PLATE.

BY

Henry U. U. Currie

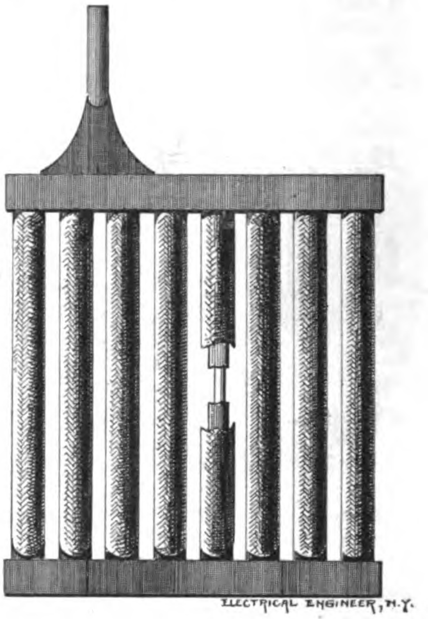
THE plate, which is illustrated in the accompanying engraving, has been devised with a view to overcoming what have hitherto proved the principal objections to storage batteries, namely, the disintegration and gradual falling away of the active material, more especially the peroxide of lead in plates constructed of this metal. There are, however, other advantages in this particular form of plate, one being the large relative amount of surface exposed to the action of the electrolyte.

The active material is in the form of a thin layer, no part of it being more than one-eighth of an inch from the internal support, while the latter is entirely encased, and therefore not exposed independently to the action of the electrolyte. In the accompanying engraving a part of the support frame is shown exposed at the top and bottom, but in the later plates all parts below the surface of the liquid are encased within the active material.

The principal feature of this form of plate, however, consists in the active material being entirely encased within a sheath or covering of asbestos tubing. The fact of this covering being in the form of a tube ensures the essential feature of strength. The asbestos is first braided in tubular form and of the required thickness. This is then cut up into lengths, eight of which are placed in a special mould, each tube, when in this mould, having a brass removable rod (of the same length as the asbestos but of considerably less diameter) passing up the centre. By means of a suitable inlet a fused salt of lead, such, for instance, as the chloride of lead, is poured into the mould and fills up the spaces intermediate between the brass rods and the asbestos tubing. The brass rods are then withdrawn, leaving the chloride of lead in a compact tubular form, the whole having an outer coating of wires or braided asbestos. The next step is that of filling the spaces lately occupied by the brass rods with pure lead or an alloy of lead and antimony, and at one and the same operation casting on a connecting bar of the same metal to hold the rods in place and to form the necessary connections.

The chloride of lead is then reduced to a state of porous lead and the plate is now ready to be fitted up and "formed." These plates after being formed can be used in conjunction with negatives of a similar type or with flat negatives of the ordinary type.

It might be supposed that the asbestos coating would introduce an appreciable resistance, but severe and continued tests have so far proved that this is not the case. Quite a number of cells, consisting of ten positives of the above described form, and eleven negatives of the ordinary flat type, have been subjected to most severe tests as regards charging and discharging and the way they maintain their E. M. F. is most remarkable. One plate, weighing about 1¾ lb., has been for some months subjected to continuous chargings and dischargings at a rate of 30 amperes and still looks "hale and hearty," and when recently tested at lower rate for capacity gave the same results as when first put up, namely, 20 ampere hours.



CURRIE'S NEW STORAGE BATTERY PLATE.

The plates have recently been greatly improved in shape, and, what is of great importance, a very simple, novel and inexpensive method of manufacturing them is now in operation.

SOLDERING GLASS TO METAL.

AT a recent meeting of the Société de Physique, M. Cailletet described a process of soldering glass and porcelain to metal. The glass tube to be soldered is first covered with a thin coating of platinum or silver, by treating it with a film of platinum chloride or silver nitrate and heating to dull red. A ring of copper is next electro-deposited on the platinised tube, which can then be soldered like any ordinary metallic tube. Solderings effected in this manner are said to be very strong. The top of a tube attached to M. Cailletet's apparatus for liquefying gases terminates in a soldered end, and successfully resists pressures of over 300 atmospheres.

THE NEW WENSTROM STREET CAR MOTOR.

AMONG the first to recognize the importance of reducing the number of gears in electric street cars was the Wenstrom Consolidated Dynamo and Motor Co., and as a result they, some time ago, adopted a slow speed motor geared direct to the driving axle of the car. The design of the new motor, which is illustrated in the accompanying engraving, Fig. 1, is due to Mr. H. F. Parshall, and while he has retained the general principles of the Wenstrom dynamo, he has so far surpassed any results heretofore obtained in this machine, that the marked superiority of the motor is fairly due to him.

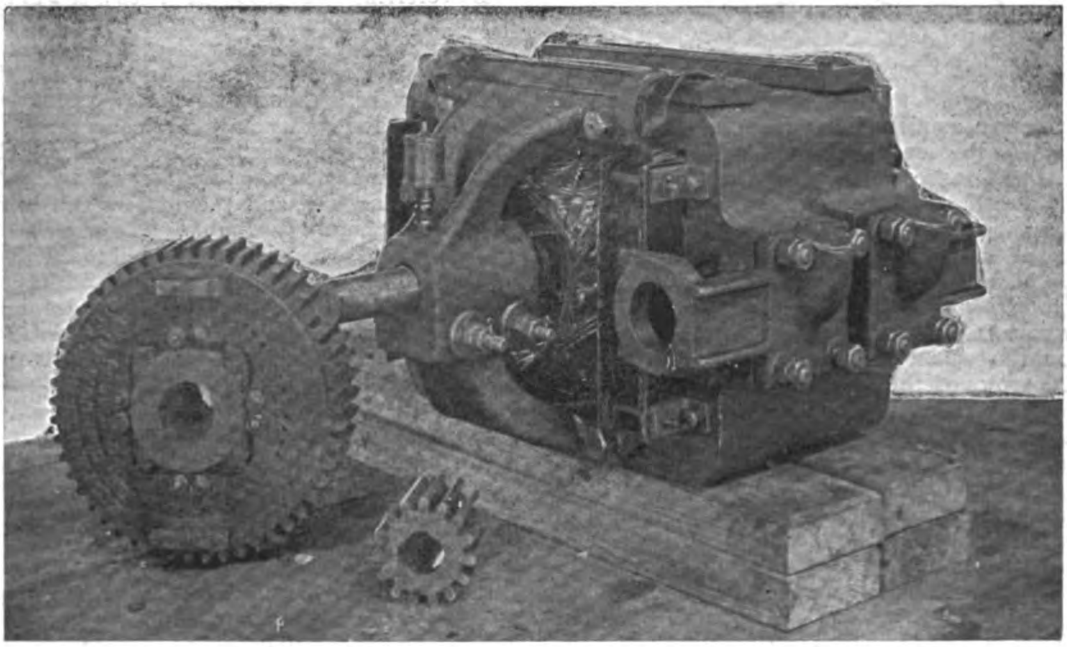


FIG. 1.—NEW WENSTROM "SLOW SPEED" CAR MOTOR.

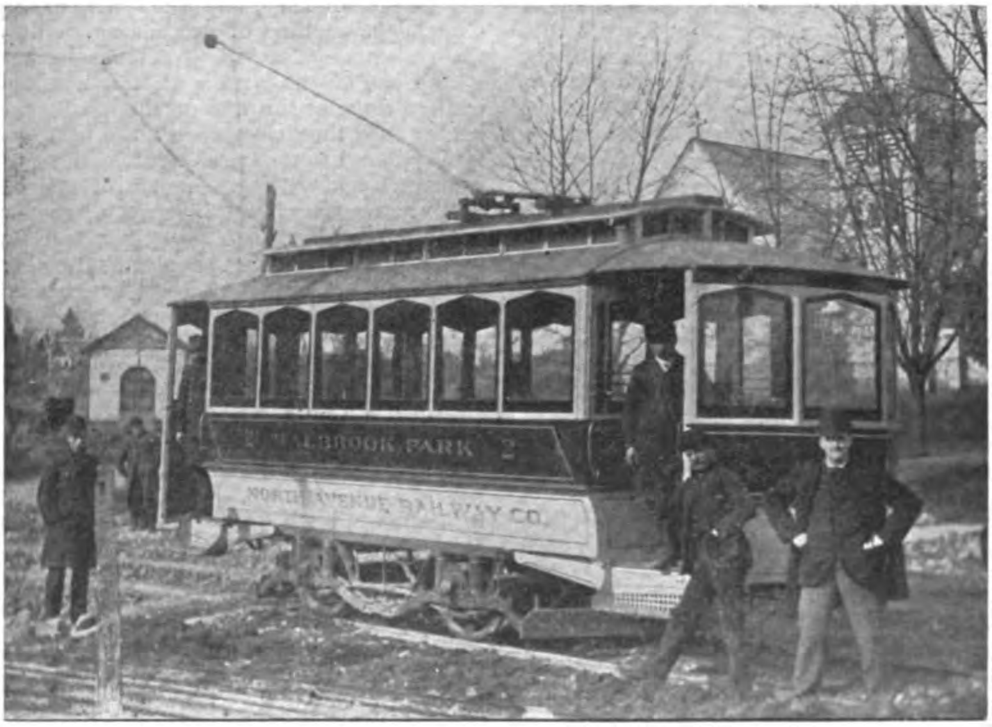

FIG. 2.—WENSTROM SINGLE MOTOR CAR, NORTH AVE. RAILWAY, BALTIMORE, MD.

The armature makes but 400 revolutions per minute, so that the necessity of a countershaft is obviated, the gearing being direct through a strong armature pinion.

The car, shown in Fig 2, has been in daily commercial operation on the North Avenue Railway, in Baltimore, for several weeks, during which time it has proven very satisfactory.

The car is equipped with but a single motor, and in a recent test made by Mr. L. N. Frederick, the superintendent of the road, he gives the following data of its performance: "The voltmeter at our power station, while the Wenstrom car is climbing our heaviest grade, which is 7 per cent., registers 490 volts, showing a loss of but 20 volts, and the amperemeter registers 20 amperes. Our car having the two motors shows a loss of 90 volts on this grade, registering 420 volts, while the amperemeter records from 40 to 60 amperes."

The car, according to Mr. Frederick, runs with less noise than an ordinary horse car, owing to the noiseless gears, and with an entire absence of a jerk on starting.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—XV.

(*Copyright, The Electrical Engineer.*)

BY

Herbert Laws Webb

THE battery power employed for resistance tests need not be high unless the length of wire to be tested, and consequently its resistance, be very great. For ordinary measurements five cells of battery are ample.

The connections being made as indicated, the ratio coils should be adjusted according to whether the resistance to be measured be high or low, and the coils should be unplugged so as to throw in circuit an amount of resistance approximately equal to the unknown resistance. The galvanometer should be shunted with the $\frac{1}{10}$ or $\frac{1}{100}$ shunt to prevent violent throws of the needle if the balance is very uneven at first. Assuming that we are working with the Post Office bridge, the battery key should now be depressed and the galvanometer key tapped lightly, and the direction of the deflection observed. It will depend upon the battery and galvanometer connections whether a movement of the spot to the left indicate too high or too low resistance in the coils, but this can readily be ascertained by varying the resistance considerably and noting the result. If the movement be at first to the left and the addition of a number of ohms result in a deflection to the right of the zero, then to the left means not enough resistance in the coils, and to the right, too much. These indications will, of course, have opposite meanings when the battery is reversed. It is usual to put the zinc or negative pole to line, but in testing a wire of any length with one end to earth it is necessary to take a number of readings with both currents, the mean of all the readings being taken as the resistance of the line. This method is required on account of the earth currents which occur in long lines connected to the earth, and which modify the apparent resistance of the wire when measured with different poles of the battery to line. In a long submarine cable having a total resistance of several thousand ohms, the difference between the resistance measured by the zinc current and the resistance measured by the copper current will be sometimes as much as one thousand ohms, but the mean of a number of readings made with each pole to line alternately, will give the correct resistance of the cable.

The battery key being held down and the galvanometer key tapped from time to time to ascertain whether to increase or diminish the adjustable resistance in circuit, the adjustment can rapidly be made by manipulating the plugs until the spot remains on the zero of the scale. When balance is nearly effected, the shunt should be decreased, and finally removed altogether, so as to obtain the maximum sensitiveness of the galvanometer in arriving at the final balance.

As a general rule in measuring the resistance of land lines, whether overhead or underground, the distant ends of two wires are joined together and the resistance of the loop is taken. The resistance of each wire is then half the resistance of the loop. This, of course, is only permissible when the two wires are of equal length and of the same diameter.

If the conductors to be measured are connected to the instruments by long leads, the resistance of the leads should be measured, their ends being connected together and the test made in the manner described above. The resistance of the leads must be deducted from the observed resistance of the wire or cable being tested.

In measuring the resistance of a long line where only one end is available, the distant end being put to earth, several readings should be made with each pole of the battery to line; the mean of the several readings will give the actual resistance of the wire. In measuring the resistance of a loop or metallic circuit, a single reading with either pole of the battery will be sufficient; no connection being made with the earth, there is no chance for earth currents to affect the readings.

By referring to Fig. 35 (see p. 195), it will be seen that the dial bridge, besides having the advantage of a greater range of resistance, is somewhat more convenient to use (where the instruments are permanently set up) than the Post Office pattern, although the latter has no equal as far as portability and compactness are concerned. With the dial bridge the ordinary battery key is used, and the battery can be turned on and kept on without the necessity of holding down a spring key, and the battery can be reversed when requisite without any trouble. The wires from the ends of the proportional coils are connected to the short circuit key of the regular set of instruments, and by means of this the galvanometer is opened and closed for observing the progress toward effecting a balance. There are fewer plugs to manipulate, and the amount of resistance can be read directly from the dials. This renders work somewhat quicker than with the Post Office bridge. A very quick acting dial bridge is made by having a revolving arm pivotted to the block in the centre of the dial, the under surface of the arm making a rubbing contact on the sectional blocks. In this way plugs are dispensed with altogether and measurements can be made with great rapidity owing to the extreme ease with which the adjustment can be made. Such an arrangement, however, is open to the objection that resistance might be introduced at the contacts owing to wear at the bearing of the revolving arm, and insufficient pressure between the lower surface of the arm and the blocks. The possible error from these causes, if the instrument is thoroughly well made, should be very small, and where very great accuracy is not absolutely essential, a bridge of this type would no doubt meet with much favor, owing to the saving of time effected by its use.

The operation of measuring the resistance of a conductor is a very simple one, and a practical example will suffice to explain the method of proceeding. We will assume that the resistance of a wire five miles long is to be measured. If the end of the wire is directly available it is connected to the bridge at the end of the proportional arm, or, if a lead is used the resistance of the lead is taken first. The lead is found to measure .36 of an ohm. The wire is then connected and a certain amount of resistance is unplugged in the coils, approximately equal to what we believe the resistance of the wire to be. This resistance being a comparatively low one, the proportional coils are unplugged in the ratio of 10 to 100, 10 in the arm next the cable and 100 in the arm next to the adjustable coils. In this way the resistance in the coils will be ten times that of the cable, and we can make the measurement with greater accuracy. The galvanometer should be shunted, as probably the first trial will not nearly give balance and there will be a rush of current through the galvanometer causing a violent deflection when the short-circuit key is opened. The key should be lightly tapped, and not held down until balance is nearly obtained. Having plugged 1,500 ohms in the adjustable coils, we find on tapping the short-circuit key that this is not enough, and more resistance is added until the deflection is lessened and finally commences to rise on the opposite side of the scale. As we approach a balance the shunt is removed, giving the maximum sensitiveness of the galvanometer. When the deflection begins to be on the opposite side of the scale the resistance in the coils is slightly decreased and balance is obtained, *i. e.*, the spot remains on the zero mark with the short-circuit held open, with 1,745 ohms resistance in the coils. The resistance of our cable is therefore 174.5 ohms; subtracting .36 ohm, the resistance of the lead, we get 174.14, and, dividing by five, we find that the conductor has a resistance per mile of 34.828 ohms.

When possible, as in measuring the resistance of wires in cables containing a number of conductors, it is better to join a pair of wires together at the distant end and take the resistance of the loop. The two ends are connected to the bridge, and the two battery wires also, all ground connections being dispensed with. The figures obtained must, of course, be halved to give the resistance of a single conductor.

A PROBLEM IN PHOTOMETRY.

BY

Rufus B. Aisey.

With reference to the "Problem in Photometry," submitted by "A. T." in The Electrical Engineer of Jan. 28th, permit me to offer the following, as possible solutions to the questions propounded.

No. 1. If in a photometer, the distance from flame to scale is used in the determination of the value of the light, the interposition of a screen with a hole in it will allow but a portion of the beams to pass the obstruction, therefore the distance from the flame to the screen would appear as the proper measurement of the power of the candle.

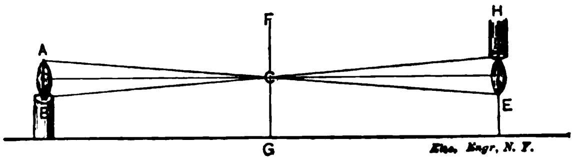

Fig. 1.

In Fig. 1, let AB represent the flame or unit, and its light projected upon a scale placed at H. If a screen, F G be interposed (which for readiness of comparison is placed midway between scale and light), the power of the candle is diminished by exactly the number of rays failing to pass the screen, which would be exactly ½, hence the light of one candle power having a screen interposed, would be reduced in intensity ½, or the distance from screen to candle, or screen to scale. If the screen were moved closer to the light, the image on the scale would be fainter, until the relative positions of the two were restored.

This may be proved by substituting for the drawing or scale, a sheet of plain unruled writing paper, folded crosswise of the sheet so as to present a square, whose centre shall coincide as closely as possible with the centre of the flame under discussion.

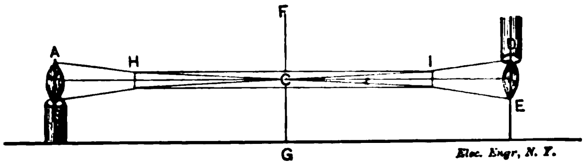

Fig. 2.

Now, letting the folded paper stand on edge, with the sides open at an angle of 45°, at any given distance from the light, and by placing another light equi-distant, the lights presumably having the same power, it will be found that the folded paper, being equally illuminated on both surfaces, presents a perfectly flat appearance, giving no indication of being interposed between the two lights. Now, if a screen be placed at a point midway between the apex of the paper and either of the lights, the reducing of the beams in parallel will necessitate a moving of both screen and light closer to the paper, until the lamp will occupy the point where the screen was first interposed, and the screen will still be midway between the paper and light, when the illumination of both sides of the paper will again be equalized, and appear as a flat surface.

In proposition 2, we seem to have an absurdity, but taken within reasonable limits, it would appear capable of the same solution or answer as proposition 1.

As an absurdity it would only be necessary to exaggerate the length of the tube until it reached both flame and scale, or to have the light-passing capacity of the tube reduced to microscopic fineness. But, while in my sketch I have somewhat exaggerated, yet I have kept within reasonable bounds.

Let H-I Fig. 2, represent the screen or tube. It is very evident that only those rays of light will be enabled to pass, which can be passed parallel to the tube, thus forming a round beam, slightly larger than the tube, upon the scale. Let us now suppose that through a suitable aperture in the centre of the length of this tube, a screen be introduced; the parallel beams are immediately made to come to an apex, and after passing their point to again diverge, until upon the scale the image is again shown as in the first proposition.

If the conditions of the question propounded were altered to make the tube begin at AB and gradually narrow to a point at C, thence expand again until it reached the scale at DE, the proposition would be answered by the conditions attached to Fig. 1, and may be also considered as answered under the same conditions in Fig. 2.

For the 3rd problem, we have entirely different conditions existing. Here a light placed in the focus of a concave or parabolic mirror has both the direct as well as the indirect rays utilized, and thereby the power of the light is increased. Now to get at a measure of this increase in power, let us substitute a double concave lens for the mirror, and place the lamp behind it; it will be found that the lamp will be in position at a point measuring the same behind the lens as before it; consequently in estimating for the distance or measurement to the scale, the measure should be taken from a point as far behind the mirror as the light is in front, which would be the radius of the mirror. Now, presuming the image of the inverted candle to be thrown upon the scale by placing a screen or diaphragm, as in Figs. 1 and 2, the proper position of the screen will be found to have been moved to a point nearer the scale, by a distance equal to the radius of the mirror. Hence, the deduction from the premises, that, to obtain a measuring point for the power of a light placed in front of a parabolic lens or mirror, a distance corresponding with the radius of the lens should be added to the distance of the lens from the scale in computing the candle power.

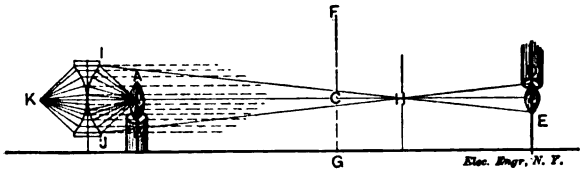

Fig. 3.

THE MEASUREMENT OF LARGE CURRENTS.

For the accurate measurement of large currents, such as are obtained from accumulators, F. Himstedt makes use of a tangent galvanometer, with two consecutive copper rings, each 1cm. broad and .4cm. thick, of radii 23.276 and 27.422 cm. respectively. These rings are connected in opposition, so that the needle is acted upon by a differential couple. The advantages of this method are that the measuring apparatus is inserted in the actual circuit, that only a single observation is required, and that no resistance measurements are necessary.

THE CARBON BRUSH FOR DYNAMOS AND MOTORS.

BY

Edgar A Sweet -

THE frenzy which has taken hold of electrical inventors is throwing many intricate devices upon the market, which keep the studious electrician of the present day up to his ears in electrical technology; of these devices many, indeed, are meritorious, possessing qualities that at once recommend them to foremost positions. But so eager are some of our inventors to rush their apparatus upon the market, in order to gain priority over others, that often the device is wanting in its most essential requirements.

We all know what the principle of dynamo machinery is—an armature moving in a magnetic field—and of the various types of this class of machinery; but they all seem to fall short in one most important point, important at least to the business manager of an electric plant, namely, the device for collecting or transmitting the current from, or to, dynamo electric machinery. There are some dynamos that would require a three-length commutator in order to offer surface enough for the collectors to carry off the enormous current generated.

A low potential current is the most difficult one to handle by means of either copper or carbon collectors, and it is impossible with the present carrying capacity of the collectors, to carry it off without more or less damage to collectors and commutators, and, in most cases, to the final destruction of both. It is thus only a question of time when every dynamo and motor must be supplied with new commutators, the collectors themselves having in the mean time been replaced many times. The causes for this trouble are various. If one tries to carry 40,000 watts on a 22,000 watt dynamo, which is too often the case, the commutator and collectors will shortly have to be replaced by new ones. If the copper wire or leaf brushes are allowed to acquire a long surface at their contact points with the commutator, sparking is sure to ensue at the brushes, and the longer they are left in this condition, the greater is the rate of destruction.

A sparking machine should be attended to immediately; the first point of attention being the brush contacts: Are they good? Are they properly set? Do they make contact upon diametrically opposite segments of the commutator? If more than one brush to a pole is used, are they at *adjacent* contacts? This, however, cannot be set down as a fixed rule. I have found by experience that one brush is not as efficient as two, or more, of the same surface contact, for giving one brush a small lead will, in many cases, stop all sparking; this is especially so with brushes that bear upon the commutator endwise, as shown in the engravings, Figs. 1 and 2, and unlike the old leaf brushes that strike the commutator at an angle of 40 degrees and are constantly working their fingers over the segments, to the final ruin of the commutator. These endwise brushes bear upon the commutator nearly at right angles with the commutator axis, and are consequently always the same in their action.

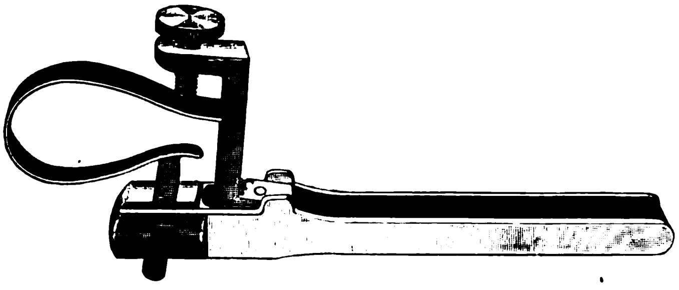

FIG. 1.—THE SWEET CARBON BRUSH.

The form of carbon brush illustrated is adapted to most forms of dynamos and motors, and, where the carrying capacity of the brush is sufficient, will give the best results. This form has been applied to dynamos where the old copper brushes could barely be kept in a running condition; dynamos generating a high potential current will take to this brush and run for years without the slightest attention. I have in mind a machine that would not cease its sparking (and this even at the high tension rings of an alternator) while running with copper wire brushes; but the application of this form of carbon brush stopped all sparking, and the machine did not, in one year's time, wear one-tenth of an inch from the one-inch carbons that were placed in the holder slip. The result was remarkable, and the commutator remains to-day as smooth as when first turned off, more than one year ago.

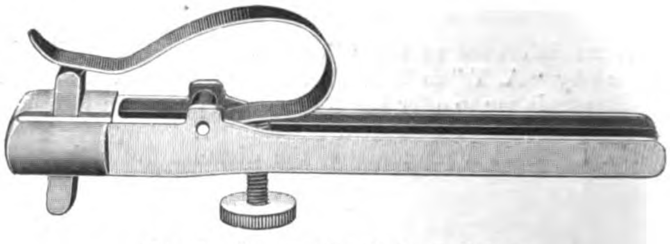

FIG. 2.—THE SWEET CARBON BRUSH.

A carbon brush that presses vertically, or nearly so, on the commutator, must, according to dynamic laws, give better results than a brush placed at an angle of 90°.

A collector is supposed to be thick enough at its commutator contact end to exactly cover one of the coil segments. The brush that bears at an angle of 90° will wear at the point of contact, drawing it out over the commutator until it covers more than one segment or coil, thus causing a short circuit of one coil in the series wound armature. Sparking will then follow; the commutator and armature will heat, not only from the sparking, but because one or more of the armature coils are partly, or wholly, short-circuited, and generating heat; and, finally, if the brush contacts grow too long, the armature will burn out.

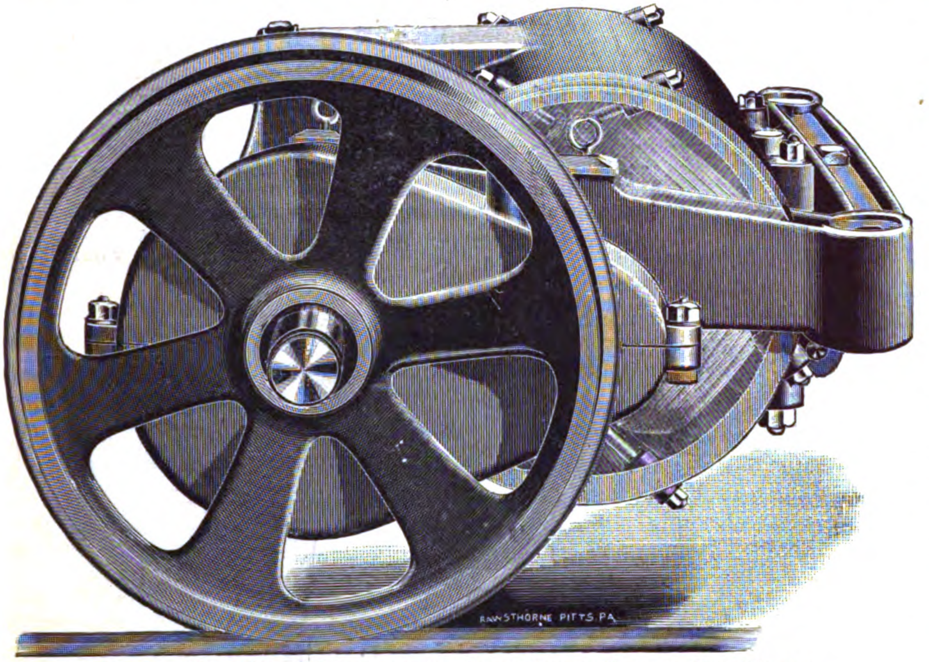
PARAMAGNETIC AND DIAMAGNETIC BODIES.

A NOVEL distinction between paramagnetic and diamagnetic bodies has been pointed out by M. P. Joubin in the current number of the *Comptes Rendus*. For those metals which obey Dulong and Petit's law of atomic heat, it is possible to calculate quantities which are proportional to the number of molecules contained in a unit volume, and hence the average distance of the molecules from each other can be compared. When these distances are examined in connection with the corresponding values for the specific resistance, it is found that the metals arrange themselves into two groups, those in one class being paramagnetic, while the remainder are diamagnetic. The two curves which represent the results graphically are found to be such that the number of molecules per unit volume is proportional to the sixth root of the specific resistance for magnetic bodies, and inversely proportional to that quantity for diamagnetic ones. A comparison of the thermo-electric powers of the metals, with the corresponding molecular numbers, yields a similar result, the metals dividing into exactly the same groups, although the shape of the curves is somewhat different, and it is significant that a comparison of the magnetic coefficients, as far as our present knowledge of these quantities renders it possible, leads to the same grouping.

MANSFIELD, PA., is one of the latest towns in western Pennsylvania to operate a central station plant of electric lighting. The Westinghouse alternating current system has been installed.

THE NEW WESTINGHOUSE SLOW SPEED MULTIPOLAR RAILWAY MOTOR.

Our readers will recall to mind that in our issue of Oct. 15, 1890, we described the Westinghouse electric street railway motor which has since gone into successful operation on a number of railroads. This motor was of the usual two-pole high speed type, requiring double reduction gears. Since then the demand for slow speed motors which gear directly to the car axle has arisen, and in keeping with the progress of electric railway work, the Westinghouse Company has now brought out a new type of motor embodying slow speed, and gearing direct from the armature to the car axle.



RAWSTHORNE PITTS PA.

Fig. 1.—The New Westinghouse Slow Speed Street Car Motor.

As will be seen in the accompanying engraving, Fig. 1, the general form of the motor is cylindrical, giving the maximum strength with a minimum amount of material, and thus reducing its weight. By eliminating sharp edges and corners, this form prevents the radiation of the lines of force, and consequent loss from external magnetism accompanied with a tendency to draw pieces of iron into the revolving armatures.

The machine, as will be seen in Fig. 2, is of the multipolar type, there being four poles. The field coils are composed of wire having exceedingly large carrying capacity, and by their low resistance adding to the efficiency of the motor. The field spools are thoroughly insulated, being as carefully wound as are machines designed to carry 1,000 or 2,000 volts. The core is of a specially soft grade of cast iron, having excellent magnetic properties. Again, the fields having narrow pole faces, reduce the reaction or demagnetizing effect of the armature on the field, and render the lead more constant, in turn reducing the liability to sparking at the commutator. Moreover, the poles being narrow, are magnetized with the least possible length of wire, which in turn offers less resistance and also increases the efficiency of the machine.

The armature is of the drum type, the core being built up of laminated grooved iron plates, so that the complete core has slots to receive the wiring. The wires being completely embedded below the surface, are not liable to injury from external causes and can have no lateral motion. They are covered above by strips of insulating material, and, when finished, the surface of the armature is perfectly smooth, so that the distance between the armature and faces of the field poles is reduced to a minimum, thereby greatly increasing the efficiency of the motor; and, should the journal bushings become worn so as to bring the surface of the armature core in contact with the fields, the wires, being below the surface, would not be injured. This method of winding is very simple, and repairs can be made by an ordinary workman. The peripheral speed of the armature is comparatively slow, as the wires move only 1,250 feet while the car passes over 1,000 feet, thus running at only about one-fourth the velocity of the high speed motor.

The commutator has been specially designed wholly for street car work, and so constructed that heating, should any occur, produces no unequal expansion, and obviates the tendency of the bars to become loose. Each bar or segment of the commutator has a bearing beneath, extending its entire length, rendering it impossible for a bar to become bent or moved out of place.

The brush holders are supported by a square oaken bar attached to the side of the frame, and are so clamped that they can be readily detached. The carbon brushes are placed in the sliding frame and press against the commutator by a pair of springs, which can be readily released for the purpose of removing the carbon and replacing it when it becomes worn. The brushes rest upon the upper part of the commutator, and, the greater part of the surface of the commutator being exposed above, it can be readily cleaned from the inside or from the outside of the car.

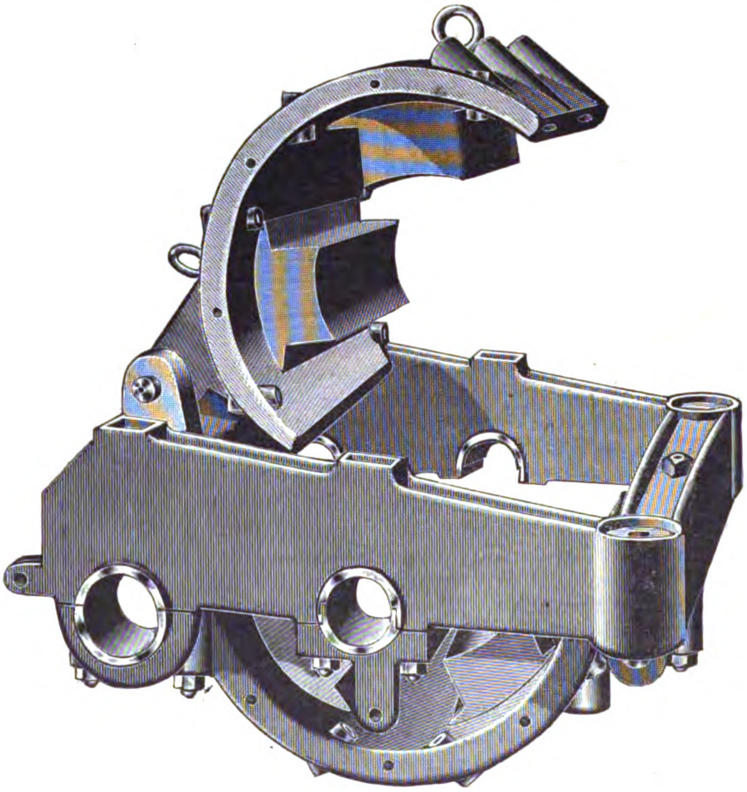


Fig. 2.—Westinghouse Street Car Motor Frame.

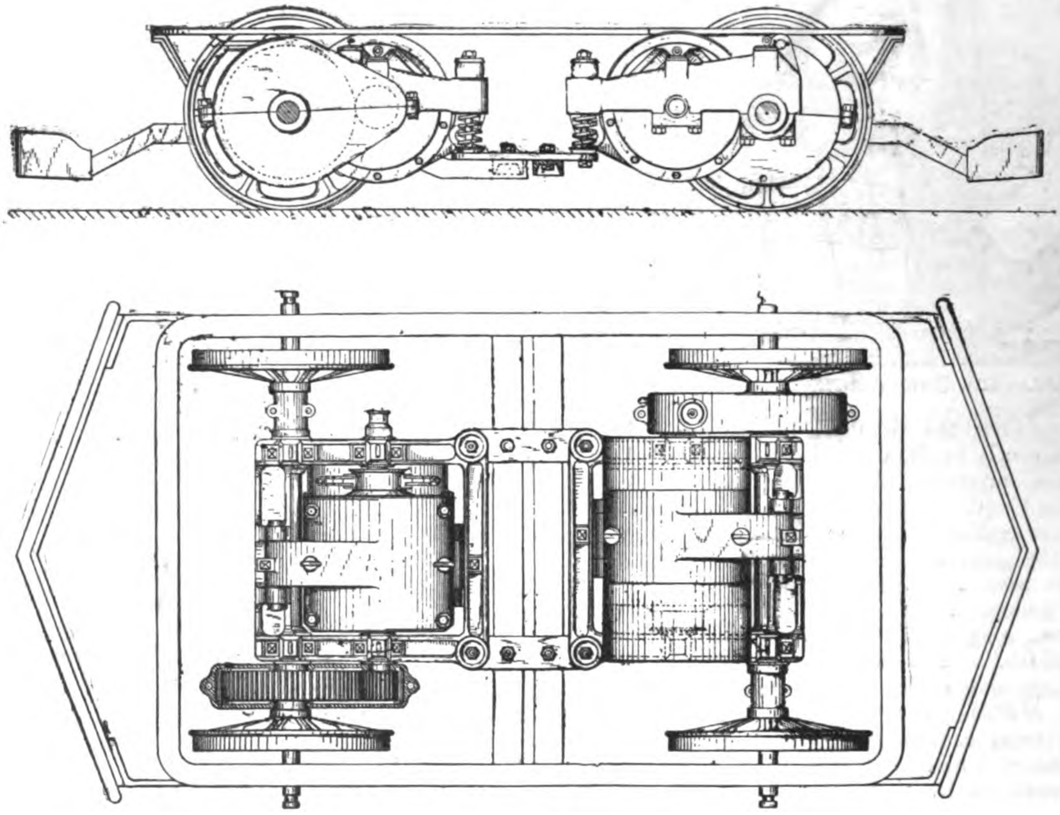
The cast iron frame on which the motor is mounted is rectangular, made in one casting, and is especially strong at points subject to the greatest strains. The frame being extended completely around the motor and suspended at both corners, the strains are distributed and the abnormal wear of the bearings is thus avoided. The frame maintains the armature and car axle always in perfect alignment, and produces a perfect meshing of the gears.

The field castings, as will be noted, are hinged and can be readily swung back, as shown in Fig. 2, thus giving easy access to the fields and armature. The lower field can be removed similarly to the upper by swinging back the lower semi-cylinder. Thus, it will be seen that any field can be removed without disturbing any other part of the motor. The armature can also be readily taken out and lowered into the pit by means of a sling, after the lower semi-cylinder has been swung back and the bushings removed, so that it is not necessary to remove the frame or body of the motor from the car truck when repairs to any one part are necessary.

The armature shaft is manufactured from the best forged steel, especially prepared, and the ends are tapered to receive the pinion which is fastened by means of a special tightening device. The advantage of this construction is that when the pinion becomes heated and expands, it is forced along the shaft, causing it always to maintain a tight fit, and also allows of its being readily removed and replaced.



Figs. 3 and 4.—Plan and Elevation of Westinghouse Motor on Truck.

The ratio of gear reduction is only 3.3 to 1. The gears are encased in cast iron housings partially filled with a lubricant. The housing prevents dust and dirt from getting into the gears, thus increasing their life and completely deadening the noise. The motor being almost entirely surrounded by iron, it is thoroughly protected, so that pans, sheet iron coverings, etc., are unnecessary. The field coils are not only protected from the outside, but from the inside by the heavy brass cap. By fastening plates on the sides by means of the holes shown in the sides of the semi-cylinders, the motor is completely shut in and thoroughly protected from rain and snow. The upper part is also shielded from water that may leak through the car floor or platform.

Figs. 3 and 4 show the motor mounted on a truck, one gear shown being encased and the other open.

THE "INFANCY" OF ELECTRICITY.

BY

John E. Sweet.

The following is a copy of a paragraph taken from an old publication, which, although the title page and date are gone from the book itself, must evidently have been printed in 1788 or 1789, as nothing in it appears to bear a later date. The work is evidently a cyclopedia of the sciences, with twenty of the large pages in text and two pages in fine steel engravings devoted to electricity:

> Since the time of this discovery, the prodigious number of electricians, experiments, and new facts have been daily produced from every corner of Europe, and other parts of the world, is almost incredible. Discoveries crowded upon discoveries; improvements upon improvements; and the science ever since that time went on with so rapid a course, and is now spreading so amazingly fast, that it seems as if the subject would be soon exhausted, and the electricians arrive at the end of their researches; but, however, the *ne plus ultra* is, in all probability, as yet at a great distance, and the young electrician has a vast field before him, highly deserving his attention, and promising further discoveries, perhaps equally, or more important than those already made.

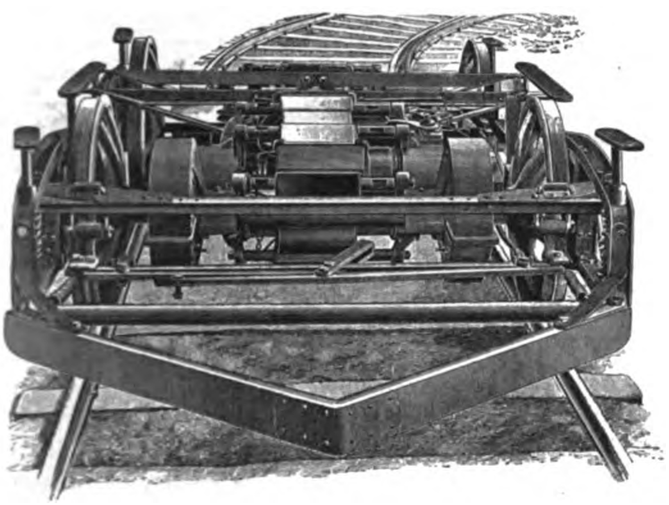
When one considers that what is said in this quotation was written probably 102 years ago, before what we now know as a battery was invented (although the word battery and electric light appears as familiar as in our present literature), the extract is highly interesting. Many other passages are about as interesting as the one quoted.

A HELMHOLTZ MEDAL.

Prof. Helmholtz will celebrate his seventieth birthday on August 31. In honor of the anniversary, a marble bust of Prof. Helmholtz will be prepared; and it is proposed that there shall be a Helmholtz Medal, to be bestowed on the most eminent German and foreign physicists. An international committee has been formed for the purpose of carrying out these schemes.

THE NEW BAXTER ELECTRIC STREET RAILWAY MOTOR.

In a recent issue we described the new slow speed, direct geared, street railway motor of the Baxter Electric Motor Co., and are now enabled to present an end view of the motor and truck. The eight-pole motor employed has a Gramme ring armature which revolves at a speed of 420 revolutions per minute when the car is running at a speed of ten miles an hour. As will be seen, the gears and pinions are enclosed in a dust and air-tight casing that is partially filled with oil, which reduces the wear to a minimum, practically renders them noiseless, and at the same time affords perfect lubrication, not only to the gears but to all bearings. This casing is virtually the frame of the motor and adds little to its dimensions or weight. To increase the efficiency of the motors and avoid torsional strains and tendency to side play, a pinion is placed on either end of the armature shaft, each meshing with a gear on the axle. The space on the shaft left available by the use of the Gramme ring armature allows of the use of the two pinions without crowding the armature. To prevent any binding in the bearings while taking curves the motors are suspended upon a universal joint. Owing to the compactness of the motors, ample space is left in the wheel base for a frame work or cradle, spring supported from the truck, which carries the resistance box, and to which the motor suspension is attached. Another important feature is the ample clearance, namely, six inches, between the lowest part of the machinery and the pavement. Both brushes are placed at the top of the commutator, so that by removing the trap door in the floor of the car they can be readily gotten at. The car is governed by a single crank lever under the control of the driver, the car going ahead or reversing in the same direction as the movement of the crank lever and the speed being exactly in proportion to the distance through which the crank is turned.



BAXTER SLOW SPEED MULTIPOLAR STREET CAR MOTOR.

HOUSETOP WIRES IN NEW YORK.

At the last meeting of the Board of Electrical Control, the Mayor introduced three important resolutions. The first requires the Subway Company to build subways where needed in all the streets to be repaved before the new pavement is laid. This is to prevent the tearing up of the pavement after it is once down.

A second resolution requires the removal of all housetop wires in districts where there are subways, within thirty days. After that time the wires will be cut down by the Department of Public Works.

The third resolution requires the removal from the streets before June 1, of all electric wires and poles in that part of the city bounded by Third and Eighth avenues, Eighth and Fifty-ninth streets, as the Mayor claims that there are sufficient subways now in that district to accommodate all the wires. After June 1, the remaining poles and wires will be taken down by the Bureau of Encumbrances.

NOTE ON THE INTENSITY OF TELEPHONIC EFFECTS.[1]

BY E. MERCADIER.

The intensity of telephonic effects depends chiefly upon the thickness of the diaphragm, its diameter, the intensity of the magnetic field, the form of this field and the induction coils.

The influence of the thickness of the diaphragm has already been investigated (vide *Comptes Rendus*, April 5th and 8th, 1889), and it has been shown that, for every telephone of a given magnetic field, there is a certain thickness of diaphragm which gives a maximum intensity.

This thickness having been found, it remains to be determined what diameter gives the best effect. The magnetic field of the core only produces a sensible effect within a limited region of the diaphragm, which is not increased by an increase of area. Such an increase, it is true, adds to the flexibility, and favors the vibration of the diaphragm, but, on the other hand, its mass is increased, and therefore more difficulty is encountered in producing these vibrations. Hence, the best diameter will vary with the intensity of the magnetic field, and, therefore, it is necessary to combine the proper thickness with the proper diameter, according to the intensity of the field at disposal. The influence of the field, however, is far from being as great as might be supposed at first sight.

Very varied experiments have been made on this subject in magnetizing the cores of soft iron of the induction coils by means of an electro-magnet, instead of fixing them, as is commonly done, at the poles of a magnet. It is thus easy to produce magnetic fields of very different intensities, by causing the current which excites the electro-magnet to vary in intensity. By working in this way it is easy to arrive at a certain limit at which the effect of the telephone does not vary sensibly, this limit being reached when the mass of the iron becomes rapidly incapable, as it were, of absorbing all the lines of force of the field, and more and more of these lines traverse the diaphragm.

This can be tested by scattering some fine iron filings upon the diaphragm, and observing that an increasing portion of the field becomes useless in the production of telephonic effects.

It is necessary, further, to observe that these effects are due to the deformations of the lines of force of the field; that these resist the deformation due to the energy of the waves arising from the voice, according as the magnetic field is more intense, and that this energy is necessarily limited. These remarks apply equally well to the telephone receiver.

It is evident that, other things being equal, the best form of field is that in which the lines of force are perpendicular to the direction of the wire in the coils. Moreover, the variations in the form of the field may be facilitated by the mobility of the field, and this can be increased up to a certain point by the mobility of the magnet and of the cores of the coils.

In summing up the foregoing facts, it seems that the following conditions are those by means of which it is possible to obtain the best results from a telephone, namely:

1. The mobility of the lines of force of the field should be favored.
2. The lines of force should be cut by the greatest possible turns of wire of the coils, and perpendicularly to their direction.
3. The thickness of the diaphragm should be diminished until it is just sufficient to absorb the greatest number of lines of force existing in its vicinity.
4. The ratio of that part of the diaphragm which comes under the influence of induction to the whole of the diaphragm should be increased.

NEW YORK SUBWAYS.

A bill has been introduced in the State Senate by Senator Roesch, of Tammany, which seeks to legalize the transfer by the Consolidated Subway Company of those of its subway conduits that are used for telephone, telegraph, and other low-tension wires to the Empire City Subway Company.

"EL EXPORTADOR AMERICANO."—This excellent and well-known trade export journal has established an electrical department, which it has placed in charge of Mr. W. H. Fleming, a well-known electrical engineer, thoroughly familiar with the Spanish market, and its electrical needs. We hope he will be able to do a great deal in opening up the trade that is undoubtedly awaiting for electrical concerns in South and Central America and the West Indies. We note an item in the paper quoting from THE ELECTRICAL ENGINEER, which it speaks of as "El principal periodico publicado en los Estados Unidos, sobre asuntos electricos y que es considerado como la mejor autoridad, en la materia." For which gracious compliment we can only say "Muchas gracias, Senor."

EDITORIAL ANNOUNCEMENTS

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, MARCH 4, 1891. No. 148.

An observer states that there is not a plant in existence having a sufficient capacity to supply one-twentieth of the demand for light and power that now exists within practical working limits of its area of distribution.—Marsden J. Perry.

RAPID TRANSIT PROBLEMS IN GREAT CITIES.

THERE are many problems that call for settlement in modern cities, but none are more important than those which relate to rapid transit. The questions touch not only the welfare of all who have to live among large populations, but of all who visit these cities on business or pleasure. They affect more particularly our newer American cities that so often grow at an astounding rate and spread over enormous areas, the percentage of increase and the extent of ground covered being entirely without precedent in the development of urban centres of Europe.

Many solutions have been offered and tried of the rapid transit problem, but it remains, and will not down. If no new departure be taken, the difficulties of city life and city government will intensify and the end will be serious and complete disorganization. It is not easy to sum up the discomfort, loss and derangement of household and business affairs caused in New York by even a slight and trivial interruption of the schedule on the elevated roads. Yet surely by this time, some plan ought to have been hit upon, aided by modern ingenuity and invention, that would render locomotion sure, safe and speedy from one boundary of the city to the other, at any hour of the day or night, in any weather, at any season of the year.

Have we reached any such point or plan? This was the topic brought before the Electric Club at its dinner last week, and, in passing, we may congratulate the club on its endeavor to deal thus with the large issues affecting the public weal. Electricity to-day leaves few provinces untouched, and there is much good work to be done in making clear the new conditions and relations it will establish. To those whose daily work lies in the development of electrical industries, every sunrise brings its fresh surprise as to the unforeseen, far reach of the new agency and art; and if it be thus with men who are keenly watching each step forward and surmising actively as to each coming opportunity, how must it be with a public to which the nomenclature and the principles are alike mysterious and esoteric? The club can prove inestimably useful as a means of enlightenment and as a platform for the free and impartial treatment of these broad topics.

The right of electricians and electrical engineers to take special interest in the rapid transit problems of great cities was well justified last Thursday, in the series of interesting letters and speeches that followed the dinner. The floor was an open one, the most diverse and opposite methods were given the chance of advocacy, and the result was a wonderfully good all round handling of the subject by experts and specialists of deserved reputation. Such a discussion could not but be of benefit, even if it but added to the information of those present; but the fact is that, without exception, every city in this country is feeling a special interest and anxiety as to the matter and is looking for advice and suggestion.

The summing up of the discussion, of which a very full report will be found in our columns this week, must be of great encouragement to the electrical engineer, for to him evidently the great majority are looking for rapid transit facilities worthy of the name. Just what those facilities shall be is determinable largely, if not wholly, by the size and peculiar circumstances of each city, but the flexibility of electrical transmission is so great that if one method will not answer, others will. For a city of the magnitude and shape of New York, the need seems to be, and is, an underground electric road clear around the city; and the exact situation here was defined by Mr. Sprague. As a further most important contribution to the rapid transit discussion, we have also printed this week Mr. Sprague's interview in the *Commercial Advertiser*, now published with authority, and accurately, for the first time in a technical paper. If our readers will read carefully this interview and the report of the dinner at the club, they will be well and fully informed on this vital question of the hour.

ELECTRIC RAILWAY WORK.

THE uninterrupted work of improvement which is going on in electric railroading is well demonstrated by glancing through our pages this week, in which we describe no less than three different forms of slow speed, direct connected motors for connecting the armature to the car axle. We think there can be no doubt as to the superiority of the single reduction gear over the double reduction driven by the high speed motor; and while the latter has done, and is doing, good service, it seems now only to be a question of time when it will be displaced by the new type. The next evolution will be no gear at all. It was no doubt this fact which Mr. F. H. Monks, general manager of the West

End Road, of Boston, had in mind, when he spoke of the caution and reserve necessary in extending electricity on the lines of his company, notwithstanding the urgent demand of the citizens for electric rapid transit. His hint was also pertinent, that our climatic conditions are such that it might be found more desirable to employ independent electric locomotives in preference to cars, each individually equipped with its own motive power.

NATIONAL WIRING RULES.

While the requirements demanded by the fire underwriters have done much to raise the standard of electric wiring work, there unfortunately still remains much to be effected in this direction. The rules thus far laid down by the various bodies of underwriters, while all tending to secure good work, vary more or less from one another, and this, we think, is a serious drawback to their general adoption. We feel convinced that a standard set of rules, issued by the proper authority, and sanctioned by the various boards of fire underwriters, will meet with general acceptance among electrical engineers, and will be hailed with delight by many who are now at a loss which rules to follow. The National Electric Light Association is preeminently the body from which such a set of rules ought to emanate, and we hope the committee appointed for that purpose will be able to report in full at the next meeting of the Association.

THE "INFANCY" OF ELECTRICITY.

The characterizing of the present state of the art of electricity as the period of its infancy so often greets our ears, that it is time to call attention once more to the fact that, far from being in its adolescence, electricity is a science which attracted a large share of attention even in the last century. Indeed, those who will take the trouble to look up the subject will find the electrical literature of the last century by no means a small one. As bearing on this point, Prof. John E. Sweet sends us an interesting communication containing an extract from a work published apparently in the last century. Strangely enough, it was thought, even at that time, that the end had been reached, and little hope was held out that further advances would be made in this branch of science. And yet, with this statement before us, who can say that the progress which will have been made a hundred years hence will not be such as to justify the calling of this, the infant age of electricity? The passage cited by Prof. Sweet is not familiar to us but reminds us very much of the utterance of Dr. Priestley, when he held that in electricity the *ne plus ultra* would never be reached.

STORAGE BATTERY CONSTRUCTION.

The variety of forms which the storage battery has taken in order to overcome the difficulties in its management and operation for long continued periods, has often been commented on; but we think we can discern novelty in the more recent forms which have been brought out. It is evidently of paramount importance that, in order to obtain uniformity of action—the lack of which is the cause of most of the troubles experienced in the past—the electrolyte and current must be able to act equally upon every part of the active material. The recent experiments of Prof. Ayrton show in a most striking manner the inequality of the action in the forms now in general use. In consequence, we see the more recent storage batteries designed with special reference to avoid this. An interesting departure in this direction is the storage battery plate due to Mr. S. C. C. Currie, which is described in another column. By the employment of an asbestos sleeve surrounding the active material, which in turn completely covers the lead of the grid, the current is obliged to pass entirely and uniformly through the active material. The tests which have already been made of cells built on this plan, certainly show remarkable results and demonstrate not only its lasting qualities, but its capability of withstanding very heavy charges and discharges without deterioration, a quality which makes it specially valuable for street railway work.

Mechanical Vacuum Pumps for Incandescent Lamps.

The manufacture of incandescent lamps on a large scale has, perhaps, done more than any industry to develop apparatus for obtaining high vacua. That the very life and efficiency of such lamps depends upon the degree and integrity of the vacuum has been so often demonstrated, that no trouble has been spared to secure this first desideratum, and the mercury pump has, up to the present day, been looked upon as the only available means for the satisfactory exhaustion of incandescent lamps. It is true that mechanical pumps have been employed to effect initial exhaustion, but the final work has, up to the present, always been accomplished by the mercury pump. The comparatively large item of expense involved in the production of the vacuum by the mercury pump seems therefore to make it eminently desirable to find, if possible, a substitute for this expensive and tedious process. Our readers will therefore be interested in the description we give elsewhere of the Beacon mechanical vacuum pump.

The Protection of Long Circuits.

The frequent interruptions of telegraph service between the large cities this winter has led to a discussion of the subject in some of the daily papers. The writers cannot see why measures are not resorted to which shall render the wires less liable to breakage than they now are. The question has been taken up by Mr. John C. Wilson, the electrical engineer, now of Boston, who, in a letter to the *Herald* of that city, says that "in no department of electrical mechanics has so little improvement or advancement been made as in the erection of lines of telegraph." To prevent these interruptions, Mr. Wilson proposes that the wires between cities should be carried along the lines of railway in light and strong aerial tunnels of glass, iron or steel, "to the inside of which the wires could be readily attached far enough apart to prevent serious inductive interference." This plan is practically the same as that proposed for city wires by Mr. A. A. Knudson, who not long ago devised an aerial conduit to hold all the wires, and to be carried along the streets on poles. Mr. Wilson believes that his cross country aerial tunnel could be made strong enough to withstand any storm. That, of course, is the main point; and the subject is one that he would do well to follow up.

AN INTERVIEW WITH MR. SPRAGUE ON UNDERGROUND ELECTRIC RAPID TRANSIT FOR N. Y.[1]

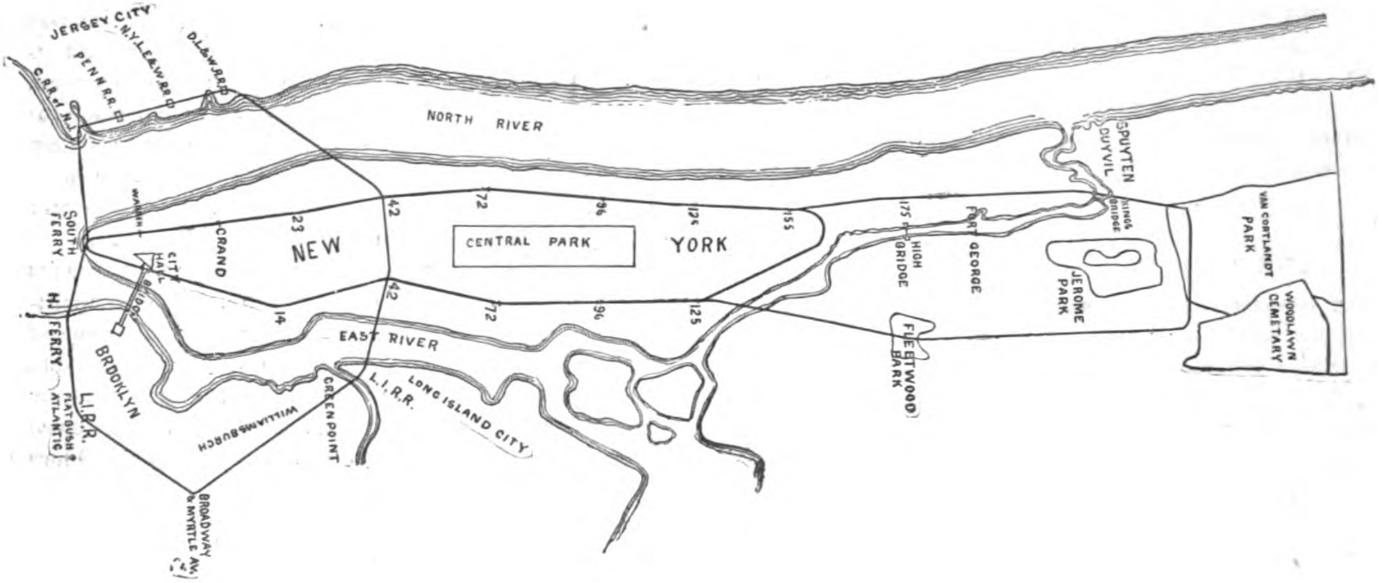
BY GEORGE HELI GUY.

MR. SPRAGUE, on being asked to give his views on the general aspect of the rapid transit question, said:—

For two years or more the question of rapid transit has easily held its position as the foremost subject demanding the immediate attention of New York. The urgent need of the city for some great improvement in its methods of communication, the eager discussion of the subject on every hand, the demand of the people as voiced by the press, by petition and by representatives, have finally made themselves felt, and we have a rapid transit bill and a commission empowered to give the necessary relief. And well it is, for New York has always been behindhand in providing for its needs.

The total annual passenger traffic—that is, the total number of persons carried in this city—has increased at the rate of over 140 per cent. in each period of ten years since 1866, and is now something over 325,000,000. At the same rate of increase it would amount in 1890 to over 500,000,000, and in 1900 to 1,255,000,000.

Rapid transit is indeed urgent, but no less important is the proper solution of a plan which shall not only meet the needs of the New York of to-day, but that greater New York to which it is our pride to look forward. The decision of the plans of such a road should be based on the broadest conception, not only of the territorial growth of the city and its surroundings, but with due regard to the changes which shall take place, when narrow streets shall give way to broad ones, when obstructions shall disappear, when permanent and perfect pavements shall be the rule, not the exception, when residences shall be replaced by business blocks, and when the most daring conceptions of architects and builders shall reach their fruition; when we shall point with pride and confidence to every municipal work.



MR. SPRAGUE'S PROPOSED SYSTEM OF RAPID TRANSIT FOR NEW YORK AND VICINITY.

To effect this would you advocate the building of the line simply on its own basis, or with regard to existing lines and outside connections?

It should be planned first of all to meet the requirements of New York city, the wants of the business and the laboring man, for women and children, for resident and visitor; to make communication as easy and as rapid as possible, not only between the residential and the business quarters of the city, but between the city and its suburbs, when such there shall be, and between the different parts of the business districts and the different parts of the residential districts; for social as well as business demands; in short, to get the most intimate communication between all parts of this city.

Such a road should not only be built in the most substantial manner, but with well-hedged privileges and franchises, which, while protecting the city in its undoubted rights, should offer the certainty of fair and equitable returns to an investor, large or small, so that its bonds and stock should be as safe and as much sought after as a government bond.

Whatever the demands of our neighbors, whatever the plans suggested for our consideration, it must not be forgotten that New York wants rapid and convenient transit now and all the time, day and night, and that of every hundred passengers on the elevated or surface roads, ninety-nine have no call to go out of New York, and are solely concerned with the best means of following their daily vocations without unnecessary loss of time.

I am not unmindful of the desirability of easy communication between New York and Brooklyn, or Long Island City, or Hoboken or Jersey City, nor the value of every connecting link commercially possible between the great trunk lines which have done so much to build up New York; but consideration of this demand should not subordinate the real issue which is before us to-day, which is: How quickest and best can the inhabitants of one part of this city get to any other part of it? The needs of New York must predominate, not the needs of its neighbors, which can properly be taken care of without sacrifice.

On what other important grounds do you advance such a view of the case?

That we may fully realize the demands of New York, it should be considered geographically. Since the annexed districts have been added, the general contour is very much like that of the stock of a fowling piece, with the breech at the Yonkers line, that is, the upper boundary of the Twenty-fourth district, the trigger-guard coming in the Twenty-third district on the east side, almost in line with the 155th street station of the elevated railroad, and the barrel end at the Battery, sixteen miles away. From the Battery to the Grand Central depot is a trifle over four miles. It is seven and a half miles to the upper end of the park, eight and a quarter to 125th street, and nine miles to the Harlem river, on the centre line of the city. Jerome Park is as far from the upper boundary as are the Bowery and Cooper Union from the Battery. One Hundred and Twenty-fifth street is the centre of New York, Central Park being entirely within the lower half. The Forty-second street depot being only one-quarter of the distance up, will, in a not very distant future, be "down town." Before 1900 its present function as a great passenger station for trunk lines will disappear, and these functions will be supplied by a larger and more magnificent depot, further north, reached by rapid transit lines.

More than one-half of the area of New York is above 125th street. With this great length, however, New York is limited by its water fronts. It attains a width of two miles at Grand street, a mile and a half from the Battery. It has the same width at Forty-second and 125th streets, and in all this stretch, its widest portion is at Fourteenth street, where it is two and a half miles. Its greatest width, four and three-quarter miles, and for a short distance only, is at about one-fourth of the length of the twenty-third district, that is, on a line through 125th street. The length of New York, then, is about six times its mean width. Brooklyn, including Williamsburg, Jersey City and Hoboken, are all opposite the lower quarter of New York, and Long Island City is opposite the second quarter.

It would seem from these facts and the wonderfully rapid extension and growth of the city in its upper section that the making of the rapid transit plan of New York depended upon the wishes or needs of our neighbors, or if the advocates of a greater municipality prefer to put it so, making the plans of the Manhattan section of New York city dependent upon the needs of its eastern and western districts, would be the height of folly.

---

[1] *New York Commercial Advertiser*, Feb. 16, 1891.

* Any reproduction of this interview in any technical journal prior to Feb. 22 has been wholly improper and unauthorized, being made without permission, and contrary to promise, from uncorrected proof slips, and necessarily in error. The present publication is authorized, and is from the proofs as corrected by myself for the *Commercial*. FRANK J. SPRAGUE.

These districts can be well and properly served, when we consider their geographical situation, by properly constructed connecting links running under the East and North rivers, which links shall be designated for that purpose alone, and not necessarily as limiting integral parts of the city system proper.

Will you briefly give your ideas as to the more prominent plans which have engaged more or less seriously the attention of capitalists and the public, of which there are no less than fourteen?

Well, if we begin with the Beach pneumatic system, that was merged into the Broadway Underground, and this in turn into the New York Arcade Railway Company, and it is now familiarly known as the "Arcade." Its advocates proposed to run from the Battery, thence to Broadway and Madison square, with four tracks, the two centre being express tracks, with stations one mile apart, and the two outer tracks for way traffic. Thence the route extends to Fifty-ninth street by Broadway, and to the Harlem river by Madison avenue, with an additional route up the west side of Central Park by the Boulevard or some other avenue and into the annexed district. Branches are proposed to connect Broadway and Madison avenue on Twenty-third street, and the two branch roads on Forty-second street.

The Underground Railway Construction Company has pooled the issues of the New York District, New York Underground, and the Metropolitan Junction Company. The route of the first is similar to that of the Arcade, and runs from the Battery to Broadway and Madison square with four tracks; thence up Broadway to Fifty-ninth street, and up Madison avenue over the Harlem river to some point near Jerome Park. Branches are also proposed from river to river on Twelfth and Twenty-third streets. The New York Underground road proposes to run from the City Hall park east to Broadway, through Centre and Mulberry streets to Lafayette place and Fourth avenue, at Union square; thence by two lines to the Grand Central, and Broadway and Fifty-ninth street, up the Boulevard to Kingsbridge, the main line continuing under Madison avenue to the Harlem river, and by a loop to Kingsbridge.

The Metropolitan Junction Company promises to connect with the two last named in the annexed districts, and then run over the Hudson by a bridge at Washington Heights, connectingwith a tunnel through the Palisades.

The City Railway Company proposes to begin at South and Whitehall streets, crossing Broadway below Rector, running between Church street and College place, Sixth and Seventh avenues to Fifty-ninth street and the Boulevard. The line would then run up the west side of Central Park, crossing the Harlem River above High Bridge, terminating in New Rochelle. Branches are proposed for the principal ferries on both rivers, the Post Office and Grand Central station. The roadway is intended to be fifty feet wide and twelve feet below the surface; it is to have four tracks, two way and two express. It differs from the other underground railways in that, instead of taking the street lines, it proposes to purchase the necessary property and erect buildings over the line of the road, which are to be rented for sufficient to pay the bonds of the company. The road thus running through the basements, so to speak, of the buildings and crossing the streets by tunnels, becomes a covered roadway instead of an open one.

The Terminal Underground Railway Company proposes a four-track underground railway from the City Hall along the proposed Elm street improvement to the Grand Central depot.

The Metropolitan Transit Company proposes two elevated steel structures, one on Broadway, between Chambers street and Forty-third street, connecting with the Grand Central depot, and the other on the west side following the line of the water front to Gansevoort market, thence up Tenth avenue and the Boulevard to Kingsbridge.

What about Mr. Heman Clark's plan?

Mr. Clark's plan is one of the most radical. He proposes a four-track tunnel, beginning near Fleetwood Park, cut in solid rock 150 feet below the surface, coming down about 100 feet west of the line of Broadway to the Astor House, where it would connect with two two-track branches, one going under the North River to Jersey City and Newark, and the other under the East River to Brooklyn and Prospect Park. Passenger stations would be at the foot of shafts sunk every two miles, and freight stations at intermediate shafts, where freight pockets would be tunneled. Large elevators would be used for handling the passengers and freight.

Then there is Austin Corbin's scheme?

Yes, one of the latest plans is that of the Metropolitan Underground Railway Company, at the head of which is Mr. Corbin. The primary object of this company is apparently to make a connection from the trunk line railroads centered in Jersey City with the Long Island system, by tunnel under the East and North rivers, with connections for the New York city systems at Whitehall street near the Battery. It is proposed as a subsequent proceeding to run four other sections, all double track, taking in the east and west sides of New York, and forming a loop around Jerome Park. The tunnel passing through solid rock its entire length, would be over 100 feet below the curb of Broadway. Stations are common to both tracks, and would be reached by elevators of large carrying capacity. Electricity is proposed as a motive power, each car to have its own motor, and a speed of thirty miles an hour to be attained. However well this scheme has been worked out, its main object is primarily for the purpose of connecting the trunk line systems of Jersey City with the Long Island railroad system, with New York as a sort of way station, and rapid transit in New York city as a secondary consideration, to be provided in some remote future after the carrying out of the initial project has been accomplished. As a matter of fact, the results proposed are contradictory, because no double track railroad operated with single car units, or, for that matter, train units of any number of cars, can by any possibility give rapid transit to New York, even to-day, much less when the road would be completed. New York cannot, and will not, make its rapid transit plans subservient to, or dependent upon, trunk line transportation, north, east, south or west, or upon the requirements of trans-Atlantic travelers.

Yet another scheme affecting New York is that of the New York and New Jersey Terminal Company, which proposes an underground railway starting from near Newark, where it is to make junction with the Pennsylvania, the Delaware, Lackawanna and Western, the New Jersey Central, the Lehigh Valley and the Erie roads; thence running under the Hackensack river to Hoboken, and thence to the western end of Fourteenth street, New York, where the tunnel would be divided, one branch running to the Wall street section of the city, and the other to a main terminal station at Union Square. Other stations would be provided for both freight and passenger service. Electricity is proposed as the motive power. While this seems a very practical scheme for making connection with the west and south bound trunk lines, it is not rapid transit for New York city.

Various other plans have been suggested, but it will be unnecessary to discuss them, but to confine ourselves to a consideration of the only one that ever came to fruition, the elevated system, and such other system as will best meet the wants of New York city.

A very inviting bill of fare, Mr. Sprague, but what do you think of the crust we now have?

The elevated system is of comparatively recent birth. It started with Harvey's elevated cable road, in 1868, which two years later was converted into a steam road and now forms the Ninth avenue division. The Third, Sixth and Second avenue railroads soon followed, and all were later consolidated into the Manhattan system, now operating many miles of double track, with an equipment of about 850 cars and 190 locomotives, and carrying about 500,000 passengers daily.

Before outlining what I think is the only proper system for New York, it is desirable to consider briefly what opportunity the Manhattan system offers for a solution of the question asked: "Can this system be made available for the best rapid transit, and if not, what can be done to improve its service?" It labors under three great disadvantages. It is a double track system, it has no loop connections, and it is necessarily limited in speed.

Its service could be somewhat improved if, as is suggested, a connection should be built along the southern bank of the Harlem river, between the Second, Third and Eighth avenue divisions, the Y connection at the South Ferry station be abolished, and property enough purchased for loop and storage tracks, so that trains could be operated in a continuous loop in both directions around the city. This would prevent some of the blocking and tedious delays which the present system of despatching entails, but it would not give rapid transit.

A thorough connection by the Second avenue line with the Harlem River and Port Chester and the Suburban Rapid Transit roads would be of benefit to the people along these routes, but they would not have rapid transit. The addition of a third track with the necessary reconstruction or stiffening of the present structure would give faster time down in the morning, and faster time up at night, but this would only be a makeshift, and would not meet the requirements of rapid transit.

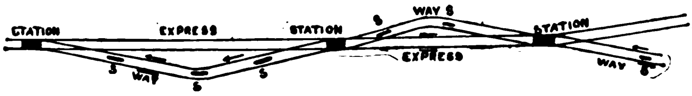
Not even on the double deck plan?

A double story, four-track system, such as has been proposed, should not for one moment be tolerated. I would not disparage the good which has been done by the elevated roads, because New York owes, in a very large measure, her prosperity and growth to them; but this should not make us blind to the inefficiency of this system to meet the wants of to-day and the future, and it should be remembered that, when the elevated roads were built, no such system of tunneling and locomotion as I shall outline was possible.

The replacing of steam by electricity, which could be done at a moderate expense, would do away with many of the objectionable features of the present system, but still we would not have rapid transit, and rapid transit is the living, crying need of New York to-day.

What is your idea of the plan best fitted to meet the requirements of the city?

To my mind no one of the foregoing plans can prove wholly satisfactory, and the plan I favor is: An independent way and express service, each having double tracks, but having independent paths, run in independent circular iron tunnels, and forming a loop around the city from the Battery to Jerome Park. The express and way routes to intersect or join at different levels at common stations, the trains to be operated by electricity. Way tracks to have stations about every third of a mile, express every mile and a half. A loop to be provided just south of the Harlem river. There would also be a cross-town two-track system running beneath the city division, intersecting it on the east and west sides on the Forty-second street line and at the Battery, and making connection with the Long Island, Broadway and Atlantic avenue station on the east, and the trunk line depots on the west.



Express and Way Routes.

This sketch I have here shows the city express line, but not the way line.

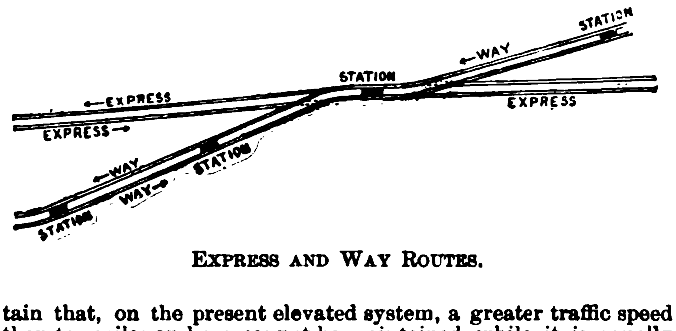
What are the considerations that make this general plan the best?

Independence of express and way service is essential. The operation of express and way trains on a two-track railroad, to meet the condition of service of New York city, should not be thought of. It is impossible to satisfactorily so operate to-day; it will be vastly more so twenty years from now. A moment's consideration of the essentials of way and express service, both in the matter of carrying passengers, making high speed, running at short intervals, handling heavy trains, economical use of power, and allowable capacity of engines will show this.

To illustrate this point, we have only to consider the work done on the Third avenue elevated road, such as it was a short time ago, and it cannot be less to-day. I have made a special study of it for several years.

This road is eight and a half miles long. Grades vary from 8 to 105 feet to the mile. The level stretches amount to about one-third of the whole distance, and this includes the stations. On the seventeen miles of single track there are fifty-two stations. In the busy hours there are no less than sixty-three four and five-car trains on the tracks. These trains, weighing from eighty to ninety-five tons, make the half trip in forty-two minutes, including stopping at twenty-six stations and discharging and taking on passengers, or at the rate of about ten traffic miles per hour. The work of the engines may be divided into three parts, overcoming the train's inertia, lifting the train on the grades, and traction, and the maximum is at least seven times that necessary for traction at mean speed on a level. Three times in every mile this weight of eighty to ninety-five tons must be started from a dead rest, raised to a speed of twenty or more miles an hour and brought to rest in about eighty seconds. The engines are run with 130 pounds boiler pressure and have a capacity of 185 h. p. Fifty-nine per cent. of the power on a round trip is used in accelerating speed, 24 per cent. in lifting and 17 per cent. in traction, and the average power developed per minute per round trip, including stoppages, is 70.8 h. p.

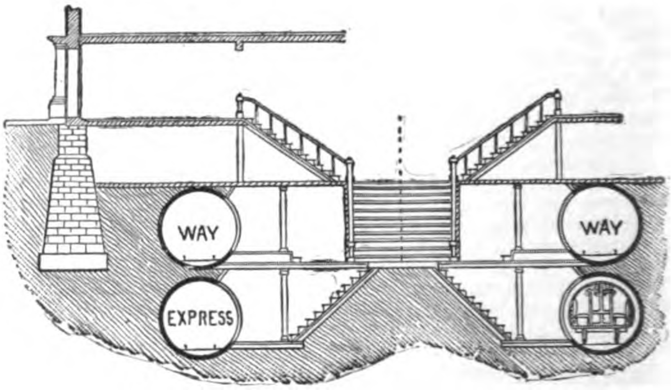
These are instructive figures, which alone should show the fallacy of a two-track system. They show that it is perfectly certain that, on the present elevated system, a greater traffic speed than ten miles an hour cannot be maintained, while it is equally true, on the other hand, that we cannot consider any less frequent stations for way service than three to a mile, yet note what tremendous duty is required of engines to make even this moderate speed under conditions of frequent stops. Under the conditions here given on such portions of the road as are fairly straight and with easy grades, a maximum speed of about twenty-two miles an hour must be attained, but on a road like the Sixth avenue and Harlem division, where there are many sharp curves and grades as high as 2 per cent. the maximum speed must rise as high as twenty-eight miles an hour to make the schedule time, and this speed can only be attained on a fairly long stretch as between the Fifty-ninth and Seventy-second street stations. Ten miles an hour is slow enough way speed; it ought to be fifteen at least, which, under excellent conditions, that is, on a road free from disadvantageously situated grades and with no sharp curves, would require a maximum speed of about thirty-three miles an hour. With a long stretch between stations, the average speed is very much nearer the maximum, and the same motive power which will handle a way train on short intervals, will handle an express train at longer intervals easily at double the mean speed, say, thirty miles an hour, with a maximum of forty miles. Therefore express trains ought to stop only about once in a mile and a half, or say every fifth way station. It should be noted that on an express train, stopping at few stations, not only would much less time be spent in getting under way and stopping, but also at rest at stations taking on and discharging passengers, so that I am well within bounds when I say that a motor which can do the service of a way train at short intervals, can equally well do the work of a heavy express train at long intervals.



Express and Way Routes.

Do we need to stick to daylight travel and the use of New York city as a big sounding board?

That a rapid transit road should be built below the surface seems apparent, and the use of electricity as motive power, the modern systems of tunneling, and the perfection to which elevator service has attained, should make the advantages of an underground system clear and its success unquestionable. Any four-track system if run above ground must almost of necessity be run over a common route. If it follows the street it is impossible to get the room for four tracks, unless one set of tracks is placed above the other. The road must be largely dependent upon street grades and street curves. If cut through blocks so as to get more room and direct lines, the cost of the property condemned, and the investment necessary, would be enormous, and there would still remain the objection of crossing streets every 250 feet. Furthermore, any surface or elevated system is exposed to weather obstructions, whether in the form of a fog, which necessitates slow and cautious running, or ice and snow, which impede the way and increase the slip of the motor. An elevated structure, except when very massively built, cannot have the same rigidity that a tunnel structure has. There is always the danger of derailment, a tumble into the street, and a greater liability of train collision. If an individual tunnel construction be used, there would not only be no room for a train to fall, but a broken axle or a derailed train would not, of itself, be apt to prove serious. The tunnels would be lighted constantly and uniformly, the rails would be always in perfect condition for adhesion, of almost constant length, and the temperature of the tunnel would be almost constant. Heating of the trains or stations would be unnecessary. Ventilation could be made perfect.



Express and Way Stations.

But we shall miss our flitting glimpses of second-story scenery?

Cars for such underground system would require no windows, landscape views not being essential to rapid transit in a city, and hence can be as strongly constructed, with less weight. Absolute freedom from sharp curves, and the arranging of grades so that instead of being a detriment, they can be of positive aid in train service, are not among the least advantages of an underground system. Where curves occur, they can be either on a dead level or the grades can be so managed that they will be of service.

Would you have one large tunnel or a number of tunnels?

Having determined upon a tunnel construction, independence of express and way tracks is not all that is essential. These might be obtained if all four tracks were in a common tunnel, but when we realize some of the other conditions which must be met, and that such a four-track system could not be placed in a common tunnel less then fifty feet in width and twenty feet in height, if tracks are all on one level, or about twenty-five feet wide and high if double-banked, objections to such construction are pronounced. It is manifest, also, that if the size of a tunnel for four tracks has objections structurally and otherwise, one for two tracks must have similar objections, although in a less degree. Hence my plan is a system of independent express and way routes, each having two tracks, each carried in independent tunnels, and having their paths intersect at certain common important points, say on an average every mile and a half. I would have not only the routes of these services independent of each other, save at their common meeting points, but I would have them at all other points independent also in the matter of grade, and furthermore. I should have the tunnels of each system, while normally running side by side, sufficiently independent to permit of such variation of route for each track as the meeting of obstructions in the construction should require; or briefly, I would have four independent tunnels, all four meeting at a common station once every mile and a half, and the way tunnels meeting at common stations every third of a mile.

What are the advantages of such a method?

1. A much stronger construction is possible with the same weight of materials, because a tunnel of twelve or thirteen feet in diameter can be built with strength to support a given outside pressure with much less than one-quarter of the weight of material required to build a tunnel of four times the area, and a tunnel to accommodate four tracks would have more than four times the area of a tunnel to accommodate one.

2. At any given depth there will be far less interference with, and danger to, the foundations of a building with a small tunnel than with a large one; in fact, a tunnel of the smaller size could be run with perfect safety almost through and certainly under or alongside the very foundations of the heaviest buildings.

3. The nearer the surface a system is run, the greater the variety of obstructions which will be met; which with a large tunnel would require a very costly change of gas, sewer and other pipes. A thirteen-foot tunnel, independently run, could easily deviate up or down, to the right or left, in fact, weave its way through and around obstructions, which it would be impossible to do with a larger tunnel. This is one of the very greatest advantages to be obtained with the independent tunnel construction.

Is any special plan necessary for the express route?

The express route, if a difference of level exists between express and way tracks, should be the lower one, and being lower it can run in more direct lines with less necessity of divergence on account of obstructions. While the express tracks should thus run in the most direct line possible between main stations, the way tracks could take a more or less divergent path as determined by the best positions for the way stations. On this account the express route would be somewhat shorter than the way, which would be an important help to a quick schedule time.

If, as should be the case, the tunnel is built of iron and of circular cross section, not only will the construction be the strongest which can be built for any given clearance, but with the minimum of excavations. It would present the maximum of resistance to vertical and side pressure. The thickness can be varied to suit the condition of strain to be met.

Do you think that such a method would materially lessen the difficulties of construction?

I do; but in considering the strength of construction and facility for finding a path, we must consider the time occupied also. By sinking shafts at sufficiently short intervals, and working in both directions on all headings, the construction of way and express tunnels can go ahead simultaneously and independently, each being completed at the earliest moment, and no tunnel being dependent upon any abnormal obstruction or difficulties which may be found in the way in the construction of another. A greater force of men can be used, the debris can be carried away more rapidly, and, in short, the whole work can be carried forward far more expeditiously and safely with the independent tunnel construction than with a larger tunnel, unless the latter were driven through solid rock at a very great depth. Of course, an accurate survey of the pipes and foundations of the city should be made and a great deal of other preliminary work would have to be done. I think, however, I am safe in saying that such a survey, the determination of route, sinking of shafts, condemnation of property, and provision of necessary machinery for work, could be made in six months after a determined body of capitalists, armed with the proper franchise, which could be granted by the city, should be ready for operation, and the entire New York city line could be ready for active operation within eighteen months thereafter. The cost of such a construction would be about $500,000 per mile of single tunnel.

How would you secure the effective ingress and egress of passengers to and from the stations?

Accessibility to all trains, no matter whether way or express, or for up or down or cross-town tracks, and for change from one train to another, is an important provision. This facility of access to trains can only be had where there is a common station, which station should be between the up and down tracks, and should be roomy, well lighted and easy to reach from the street. Sole dependence should not be placed on elevator service, although such should be provided whenever of advantage. At way stations a common platform between two tracks is easily provided, because the two tracks are on the same level, and there is nothing to provide for special changes. At the common way and express stations, however, a somewhat more elaborate station system should be adopted; the depth of the way tracks below the surface would be the same here as at regular way stations, but the express tracks would be about thirteen feet lower, and preferably directly under the way tracks; thus the four trains would there occupy the four corners of a parallelogram. Elevators, when used, should be in the centre of the station, open on both sides, and operated primarily by electricity. The entrance to stations should take no street room, and hence form no obstruction; the stations and offices should occupy the first floor and deep basement of a building especially constructed for the purpose, all the upper portion of which could be utilized for ordinary business purposes, and two or more elevators could run the full height of the building from the station platform.

Crossings on grade would be rather risky underground, I presume?

There should be no grade crossings. While the importance of this rule has met with little recognition in this country, and does not mark any widespread practice here, yet it is the standard practice of the main trunk lines in London. Its merits need little comment, because whatever other conditions may exist, high speed, safety and regularity of service can only be had in a fully satisfactory manner where there is a clear right of way.

A four-track system, such as I have outlined, running up the east side, thence by loops through the annexed district and at the Harlem river, thence down the west side, completing its circuit by way of the Battery, would necessarily have cross-town connections. These should be two tracks only, and should pass beneath the main system, with access from the common station, whether express or way, and as two-track systems they could be continued under the East and North rivers. One of the most useful of such cross-town connections would be the loop already described making connection between the New York city system and the various street railway and trunk line systems of Long Island City, Brooklyn, Hoboken and Jersey City, and whatever underground railway systems might afterward be developed there. A two-track system for this loop would practically provide express service, because on a larger portion of it, that under the rivers, there would be no necessity for stoppages, and the stated intervals would be sufficiently long to allow of high speed.

From what you have already said, I presume you would virtually ignore the necessity of providing for direct connections with other lines?

I certainly would. The depth of the New York system of tunnels should be no more dependent upon that of the cross-town loop than upon the height of the elevated railroad or the Pennsylvania terminal tracks, the level of the horse car tracks, the platform of the ferry boats or the arch of the Brooklyn bridge. It is impossible to accommodate all.

There should indeed be no connection between an express and a way track, except at the despatching and siding stations, where everything could be under the most rigid personal supervision, and where the necessary complication of tracks can be properly supervised. Switches even between the way tracks and between the express tracks should be only used in a case of emergency, and the main line of rails should be absolutely unbroken. The roadbed would be of the most rigid and even character, and the weight of rail commensurate with the duty.

Could you rely on such a system for improved train service?

Train intervals and passenger requirements should determine the length of trains, instead of length of trains determining train intervals. It is not express service to have to wait ten or fifteen minutes for an express train after leaving a way one. The most frequent interval that can be safely run is that which should be adopted, of course with reasonable regard to the amount of passenger traffic, which, however, will be better accommodated at certain portions of the days by smaller units and more frequent trains. The number of cars in a unit determines the number of passengers that can be carried with a given safe interval between trains, because the time of discharging and taking on passengers will be almost constant with a given traffic per car whether the trains be long or short. So long as there is only a safe interval between a train standing at the station and one approaching it, the train unit is not too small for passenger requirements, providing the following train is not delayed. When, however, the following train has to wait on approaching a station for another train to clear the way, the train unit is too small. The use of way and express tracks would relieve that congestion of traffic which characterizes the two-track system of the elevated railroads, and which on any two-track road cannot be avoided in New York.

What shall be the motive power of such a system as you have outlined?

Electricity will unquestionably be the motive power. The hum of an electric motor is a song of emancipation. As in independent way and express system of tracks should be an essential of a rapid transit system, so also should the use of electricity as a motive power be *sine qua non*, and accepting the statement that this agent is capable of satisfying in the highest degree the most exacting demands of service, the system should be planned with special reference to its use. One great trouble with most of the rapid transit plans which have been proposed is that they have been designed from a steam engineer's point of view. Steam practice has determined not only the form of roadbed or tunnel, but also the laying of the tracks, the construction of the cars, the ventilation and lighting of the trains and the roadway, the length of trains, the system of switching and despatching; in short, there has been scant recognition of the fact that electricity has, within the past three years, jumped to the front with tremendous strides, and given practical and most conclusive proof of its pre-eminent fitness for at least all transit of this character. Many of these systems were planned before the science of electricity was in its swaddling clothes, and even recently, when electricity has been spoken of by the steam engineer, it has been with a somewhat definite idea that electrical engineers would fit their conceptions to steam demands, but this will not be done. The best informed of them know that the time has come when it will accept no secondary place; that there is nothing which steam can do in the matter of handling trains, certainly within the limits here considered, which electricity cannot, in a more satisfactory and a more perfect manner, perform.

How far does the history of the development of electric traction corroborate this view?

The development of electric traction is unequaled in the industrial history of the world. In 1886, a list of twelve or thirteen comprised all the electrical roads in operation, and this included every electrical road in the world, whether operated by the split tube, the side rail, the traveling trolley carriage on an overhead wire, the centre rail, or by a conduit or storage battery. There was little similarity in these different plans, but they all served to show that electricity, in a more or less effective way, could propel a car. But street railway men were disbelievers, capitalists skeptical, car-builders cynical, and most electricians only hopeful. Almost three years ago to-day, the 2nd of February, 1888, there was opened for traffic, a road at Richmond, Va., which presented conditions of length, grade, curves, roadbed and number of cars to be operated, which, if successfully overcome, would mark a new era in the development of electric railway traction. The conditions, while not perhaps now seeming remarkable, were then considered insurmountable, not only because of difficulties relating to street car service itself, but also because of electrical and mechanical ones. The length was from eleven to twelve miles. There was a straight grade of ten per cent.; there were grades in curves of seven and eight per cent. There were twenty-nine curves, and some were as low as twenty-seven and thirty foot radius. The road-bed was of an execrable character. Thirty cars had to be operated at one time from a common station, and some of them four miles away. That road had its vicissitudes, but its victories as well. Forty cars were operated, and no less than twenty-two simultaneously at one end of the line. The electrical and mechanical features, hastily designed and crudely constructed, were a radical departure from previous work. They constituted what is known as the Sprague system, and in the words of Franklin Leonard Pope, "Many of the characteristic features at that time designed and introduced have practically become standards in the modern system, and are found in nearly every one of the thousands of cars now in service."

The question of electrical propulsion was there settled, and that road stands as the pioneer of the marvelous development of the past three years, until there are now in operation in the United States alone, no less than 310 electric railways, operating over 2,400 miles of track, with 4,000 cars, equipped with about 7,000 motors, representing no less than 175,000 h. p. in dynamos and motors. Not less than 400,000 miles are made a day, and three-quarters of a billion passengers carried annually. Although only three years have passed, one-third of the entire mileage of street railways is electrical, and there is scarcely a road in the United States that is not considering the application of electricity.

How does electric traction compare as an investment?

Horse railroads which have been in use for over fifty years represent an investment of about $58,000,000; electric railways, over $50,000,000, while the cable roads, which have had a commercial existence four times that of the electric system, have less investment than electrical railways, or about $49,000,000. So you see there is reason for my statement that there has been no equally remarkable growth in the industrial history of the world.

The equipments of roads by this system, or detail modifications of it, now constitute a large proportion of the business of the largest four electric companies in the United States, and the system has not only gained such hold in this country, but is being introduced in Germany and Australia, is ascending the ancient hills of Fiesole, at Florence, and has invaded the dominions of the Mikado.

What is your opinion as to the City and South London electric road running underground?

That road was first designed as a cable road, but the remarkable success of electric traction in the United States had much to do with the change to an electric system, which has been carried out with remarkable success under the supervision of Drs. John and Edward Hopkinson, and by the Messrs. Mather and Platt, of Manchester. New Yorkers are indebted to the energy and skill which has made the London road a success, because it stands in the same relation to city rapid transit as Richmond stands to the street railway development in the United States. It is the pioneer on a large and costly scale of an electric railway under new conditions, which, with modifications, can be best applied to our own needs. It will do that for capitalists who wish to embark in a rapid transit project what Richmond did for those interested in street railway service. It is, of course, a far more perfect equipment than was that of Richmond, for it had the advantage of two years' experience. That it can be improved upon is no criticism of it, but simply a statement that the ultimate, so far as the public is concerned, has not been reached in methods of motor construction and government.

What would be the general features of the electrical methods you would adopt?

Well, first, with reference to the method of supplying the current. This would undoubtedly be by the overhead single conductor underneath contact system, with rail and tunnel return, despite the criticisms of what is popularly known as the overhead wire system, which is the necessary street development, with many limitations, of the underneath plan. When such a system is used in the street, it must necessarily be of light weight, have few supports at long intervals, and meet with sharp curves, heavy grades and sudden changes of grade. There must be a variation in height of wire from 21 to 12 feet from the ground, or 1 to 10 feet above the car, to accommodate railway crossings and bridge roofs, and there must be a deviation of as much as four feet either side of a centre line. The conditions of construction cause more or less flexibility of the wire and of its supports, hence the trolley pole of the, as Dr. Holmes has so happily dubbed it, "broom stick train," must have a remarkable freedom of movement, and the contact wheel must be grooved in order that the wire may govern the movements of the arm. Despite these great disadvantages of condition and service, when the line is properly erected, the operation of the system is remarkably perfect under normal conditions, even up to a speed of thirty miles per hour with an ordinary street car.

With a tunnel road, however, the conditions are entirely changed, save only that we still wish to move a train guided only by its tracks, as nearly as may be with perfect freedom between two planes. Here the overhead wire would be replaced by a rigid rail, supported at short intervals at a fixed distance from the roadbed, and following accurately the centre line of all track and switch paths. The variation of distance from the motor car top will be practically nothing if a separate motor car be employed, and the settling of the car springs under a load, if the motor car carries passengers, would be the extreme limit of vertical movement. Grooved wheels and long poles would be discarded, and replaced by an upward pressing contact having a limited universal flexibility corresponding to the movements of the car upon its springs and any little irregularity of the tracks and the overhead conductor.

We would then have a system in which the electrical part, or rather the overhead conductor, because all parts would be electrical, would be just as rigid and permanent as the roadbed, and we should have perfection of insulation, freedom from personal liability, continuous contact with a single device, and speed limited only by the capacity of the motors. With such an overhead conductor, a speed of 120 miles per hour has already been successfully obtained on experimental work.

The so-called difficulties of the overhead system would then absolutely dissappear. A centre rail system, with the conductor near the level of the tracks, must necessarily be broken at all switches, thus requiring double contacts on motor car, and cannot offer the same advantages of insulation and freedom from personal contact. The overhead system would have been used upon the London road if there had been room enough. Of this I was assured by the consulting engineer of the road.

Then comes the consideration of the dynamos and motors.

The current could be supplied to this entire system for not only the motive power, but for lighting, and, if necessary, for ventilation, by seven central stations situated on the water front at Kingsbridge, the Harlem river near 129th and 160th streets, West Twenty-third street, Jersey City, Atlantic Ferry and Greenpoint. With these stations the electrical potential would be comparatively low. The station would be operated by triple expansion condensing engines in three units, each driving a pair of multipolar slow speed dynamos directly coupled, the units being large enough so that two engines could handle the normal maximum demand upon the station. The economy of coal consumption under these conditions is too well-known to need comment.

While for purposes of traction, quick getting under way, and for marvelous braking power in case of emergency, a motor on every truck with control from a pilot car is possible and would be a great service. I think it likely that an independent motor car will be found to be more advantageous, because of the care which the machines can have, the lack of necessity to subordinate the motor to abnormal conditions, and because, with the grades which an underground system will present, and with the constant coefficient of traction which the rails would have, a motor car could be relied upon to efficiently handle six times its own weight of passenger cars behind it. Multiplicity of parts should ordinarily be avoided, and the construction of the cars which the tunnel can best have, might make the use of a motor under each car inconvenient.

It is unnecessary to go into the question of motor construction. Gearing will be done away with, slow speed motors used, directly coupled, and it is safe to say that they will be quite as reliable as the best steam locomotive.

What system of braking would you advocate?

For use on an electric train, not only is every system of braking in common use, the vacuum, the air, whether the continuous pressure or the stored reservoir system, available, but more than this, and acting with a certainty, rapidity, and delicacy almost inconceivable, is the dynamo power of the motor system.

In a perfect system of transmission, every car running on a down grade, while not accelerating its speed, and every car coming to a stop, ought to be of service in helping to propel other cars. As already pointed out, the work done on a train may be divided into three classes: First, the work of accelerating the speed, that is, from getting from zero up to its maximum speed, the process of imparting to the train a certain amount of stored-up energy, which, when trains are stopped by the use of the brake in the ordinary manner, is nearly all wasted. Second, in lifting the train from one level to another, that is, grade work; this is partially recovered on down grades, more so on express service than it can be on way service, on account of the less frequent stops. Third, traction, the work expended in hauling a train on a level.

This would be true of the cable system also, would it not?

In a cable system running on a straight line, cars which are running on down grades do help to pull others on level or up grades, but the amount of power used to propel the cable itself is so largely in excess of that used for propelling the cars that this is not of much importance, and on roads with curves it becomes even less so. Slowing down cars on cable roads is of no service in restoring energy to the system. In an electric road, however, when operated under proper conditions, all this is changed. There is intimate and instant relationship between every foot of the system, and a train slowing down, or a train running on a down grade, can give back a large proportion of the energy to the system for use on other trains. The transmission of the energy by the current proceeds with calm indifference to grades and curves, or the condition of the thermometer or the barometer, and serenely annihilates time and space. Be it hot or cold, wet or dry, the interchange of energy is perfect.

This method of braking is of great commercial importance, since by it there is a saving of about 40 per cent. in the amount of power at the central stations, and it effects a similar saving in the size and cost of stations and conductors. Instead of the current being all supplied by the main generating stations, it would be also supplied by nearly as many moving stations along the line as there would be trains slowing down or running on a down grade. In fact, the loss of the two conversions and one transmission would be fully conterbalanced, and the original horse-power at the central station would be no more than the aggregate net horse-power developed on the entire line.

Another method of using the motors for braking purposes is to brake the connection from the line and reverse the machine through a local circuit on the train, varying either the local circuit or the circuits of the machine. While in this position of braking, if the local circuit is opened and the line connection made, the machine would be instantly reversed.

How do these ideas stand the test of actual work?

Elaborate experiments have been made in handling a car without shoe-brakes by these methods of braking. When desired, the braking could be made so sudden as to cause the wheels to have a continuous skidding rotation, not such a skidding as is caused when an air brake is put on too sharply, but a rotating slip which is just enough to relieve the motor when the strain on it reaches the point determined by the coefficient of adhesion on the rails. This is the ideal method of braking, because fixed skidding and flat wheels are an impossibility and the wheels will turn until the train comes to a dead stop, although, where the braking power is put on too suddenly and exceeds the grip of the wheels, they will relieve themselves by slipping just enough to keep the braking at the maximum limit. A train so governed can be made to creep down the maximum grade of a road at a snail's pace, and in an emergency, such a car, running twenty-one miles an hour on a down grade, has been stopped and reversed within ninety feet.

When an electric motor is reversed, its action is cumulative, and thus much increases the effort to stop itself; and the higher the velocity at which it is traveling, the greater this effort. In fact it would be practically impossible, with a properly constructed railroad motor, to prevent its reversing when the switch is thrown over far enough.

Do any other points of discussion occur to you?

I do not think further argument is necessary to demonstrate the advantages of the electrical method of propulsion. This being granted, we have at hand the means for the construction of a rapid transit road far in advance of any system at present operated, and answering the peculiar demands of New York in the highest degree; a comprehensive system with way and express trains, starting and stopping promptly and smoothly, moving at a high rate of speed and running at short intervals, with none of the objectionable features of the present steam systems, and an enterprise having an incalculable influence on the future of this city, and on the health and happiness of our people.

A "RAPID TRANSIT" DINNER AT THE NEW YORK ELECTRIC CLUB.

The monthly dinner of the Club at its Club House, on February 27, was followed by a discussion of the topic "Rapid Transit for Cities." Although the night was extremely stormy, the attendance was large. President O. E. Madden called to order about 8:30, and after a "rapid transit" disposal of some routine business, letters of regret were read from the Mayor, Hon. Hugh J. Grant, and from President H. M. Watson, of the American Street Railway Association. Telegrams of regret were also received from Capt. Eugene Griffin, of Boston, and President T. C. Barr, of the Newark Street Railroad. President J. W. McNamara, of the Albany City Railway, operated by the overhead trolley system, wrote, expressing his opinion that rapid transit for all large cities would be found in underground railways, but that cities of less than 500,000 inhabitants must be content to have such rapid transit as may be afforded them by means of surface roads. "In my opinion," he said, "all roads in the near future will be operated by means of power transmitted by electricity in some form." Mr. F. H. Monks, general manager of the West End Street Railway Co., of Boston, wrote as follows: "Having given this subject most careful consideration, I am constrained to believe that a four track elevated road allowing two tracks for express trains and two tracks for way service built through the congested part of a city to the suburbs and connecting there with surface lines," with one fare all through, would meet the needs of the city for many years. Mr. F. S. Pearson. the engineer of the West End Railway, expressed the belief that in New York a tunnel system and four tracks would meet the exigencies of the case, with electricity as a motive power. He ridiculed the statements made in some of the New York daily papers as to the overhead trolley wires in Boston, and said: "In all the experience of the West End road since the adoption of electricity, there has not been a single instance of failure in the overhead lines during the storms which have played havoc with other wires. My objection to the appearance of the overhead work would seem rather absurd, inasmuch as the elevated railroad structures are tolerated." Col. F. K. Hain, general manager of the Manhattan Railway, regretted his inability to be present, and "would prefer not to give his views as to the manner in which he would grapple with the difficulties of the rapidly growing passenger traffic in New York."

Commissioner Heintz, of the Annexed District of New York, said: "We have always felt slighted, in the 23rd and 24th wards, by the fact that people do not seem to look upon us as part and parcel of the city of New York. The reason why we have been ignored is the absence of the very thing under discussion tonight—Rapid Transit. People have not had a chance to discover the whole of New York city. We owe it to ourselves to make officials understand that we must have rapid transit at all hazards, and if we do that we are bound to get it in the near future."

Mr. Frank J. Sprague began a very able address on "The Rapid Transit Situation in New York," by a summary of his views on the New York situation as given in an interview in the *Commercial Advertiser*,[1] and by saying: "There is no Rapid Transit; it is all situation." He described graphically the trials, tribulations and triumphs of electrical engineers in street railway work during the last five years, and said:—

Boston, Cleveland, Milwaukee, Minneapolis, St. Paul, and St. Louis, with all their adverse conditions of ice and snow, support the largest electric railway systems. Of all the thousands of people employed in the various duties of electric railway work, not one has ever been sacrificed by contact with the standard pressure which has been adopted for street work. Over fifty million dollars represents the investment of one class of electric motor work alone in this country.

Such has been the change wrought within the past three years. Can any observing man avoid the conclusion outlined by these facts; that the electric motor must not only be the propelling power of any rapid transit system in this city, but that system in its entirety must be designed with special reference to its use.

Not alone in street car work, where the electric motor now holds undeniable sway, but already in inter-city communication is it outstripping the steam locomotive. Between Minneapolis and St. Paul, a distance of ten miles, 13 cars are performing an eight minute service at good speeds in competition with the old established steam railway half hour service; and, although the fare including transfer to the city, systems is less than one-half that charged on the steam service, the operation of the cars is a most remunerative business. An electric railway line over 100 miles in length is now seriously projected in Austria. My own investigations have convinced me that at a frequent interval rapid service is perfectly feasible between here and Philadelphia.

---

[1] See page 278.

A most instructive table has recently been made showing a comparative statement of earnings of horse, electric and steam railways for city communication. This table comprises returns for all the street railways of Massachusetts, the entire West End Railway system of Boston, the Manhattan Elevated Railroad, and three specimen divisions of horse and electric railway service in Boston, and shows the car mileage and passengers carried, the receipts, operating expenses and net earnings per car mile and per passenger carried. The figures are most suggestive and they bear out in a remarkable way my own claims and prophesies of electric railway possibilities some years ago. To quote a few of the results, I find that on the Massachusetts railways with about 24,000,000 miles car mileage and nearly 150,000,000 passengers carried, the operating expenses per car mile are 25½ cents, of which about 10½ cents is for motive power, while the percentage of operating expenses to passenger receipts is 82 per cent. This almost exactly represents the facts on the entire West End Railway system when operated by horses. Coming to a more recent period I find that with three horse divisions making something over 3,000,000 miles, and carrying nearly 20,000,000 passengers, the operating expenses per car mile are a shade under 25 cents with the percentage of expenses to receipts about the same as before, 81.7. Three electric divisions, making nearly 2,500,000 miles and carrying nearly 16,000,000 passengers, give operating expenses of 20¼ cents and the percentage of operating expenses to receipts 64 per cent.—a most remarkable showing. Compare these figures with those of the operation of the Manhattan Elevated Railroad, which, for the year ending September 30th, '89, made nearly 31,000,000 miles and carried nearly 180,000,000 passengers. Its operating expenses per car mile was 17⅔ cents—a little over 2½ cents below that of the electric system, and the percentage of expenses to receipts 60.4 as against 64 per cent. for the electric system.

It has been generally supposed that this steam system was much more economical, but when we consider the tremendous traffic on the elevated railroads, and the fact that while they only have one engine to every four large cars, under exceptionable care, and they are the product of years of best development and experience, while the electric cars have had one and two motors for each car, exposed to the worst possible conditions, and with only practically three years' development, the difference of operating expenses is more than made up by repairs, and, I think, we can safely say that the electric motor has already impressed its stamp of commercial supremacy in the unerring imprint of dollars and cents, and with the future electric motor designed to meet the conditions of train service, subject to the same care that the steam locomotive is, there is no question that it will undeniably be far in advance.

So much for electricity. How should it be used? What shall be the routes over which to operate? What shall be the form of road? Shall it be elevated, surface or underground? How many tracks shall it have and what shall be the system of train service? Thanks to the electrical development, and thanks also to other modern engineering advances, and especially as they have been so cleverly and intelligently put into practical operation by Mr. James Greathead, whose representative I see here and who is better able than I to describe his methods as applied to the City and South London electric railway and well as other work, the answer to these questions seems to be an easy one, and it is an answer which a very few years ago could not have been given.

Mr. Sprague then reviewed the various schemes and asked: Where then shall be put a road? Underground. While I have been an advocate, and still am, to erect one solitary wire for an electric railway system to replace horse car service, I have thought perhaps that the Biblical admonition, "Dust thou art, and into dust thou shalt return," might just as well be applied when necessary to all electricity as to poor humanity. Despite the somewhat exaggerated claims of my telephone friends, I am no believer in the so called "God's free air," as applied to rapid transit systems in New York, because, what, with our lofty buildings, and the occupancy of our streets with the elevated structure and poles of various kinds, we have no free air; but, provided we go deep enough, I am a strong believer in God's freer earth, which is our common heritage; so I say again, let us go underground, but this is not all. What shall be the form of the underground construction?

Bearing in mind the character of our soil, the accessibility of the system, the necessity of running through and along side foundations of structures without weakening them, there seems to me but one really available system for New York. I favor, in brief, four independent iron tunnels, all meeting at a common station, once every mile and a half or so, the way tunnels meeting at common stations every third of a mile, every tunnel being absolutely independent in its route except at the stations, the way routes being run to accommodate the best surface intersections for existing lines of travel; and the express route, while passing beneath the way tracks at the common stations, elsewhere running in the most direct possible paths. Such a four-track system should run up the east side, thence by loops through the annexed district and at Harlem river, thence down the west side, completing a circuit by way of the Battery. This should intersect with a two-track system passing beneath the main system with access from common stations crossing New York on the 42nd street line and at the Battery, and making connections with the Long Island, Broadway and Atlantic avenue stations on the Brooklyn side, and the Trunk Line Depots on the Jersey Shore. This system comprises about 125 miles of single tunnel for New York and 30 miles of tunnel in the loop, and would provide a most comprehensive system of intercommunication. The schedule running on way service to be 15 miles an hour, and on express service 30 miles; and how different such a tunnel would be from that which we have known? A rigid iron structure with all vibration deadened by the surrounding soil, an almost perfectly equable temperature, a magnificent roadbed, perfectly jointed and free from expansion and contraction, absence from dust, smoke and cinders, perfect ventilation, a structure unobtrusive in character and absolutely safe, derailment almost an impossibility, a system of braking and signaling unequaled, and a prompt and reliable high speed service. Let us hope that we all may be prominent in accomplishing this result.

Mr. C. O. Mailloux, speaking of rapid transit in Washington, where he is putting in a plant for 40 storage battery cars for the Metropolitan Co., said: "The bill passed by Congress forbids the use of any overhead appliances. That restricts the systems to the underground electrical, the cable and the storage battery. All things being considered, there was only one thing left to do, and that was to use the storage battery system, which I hope can be developed to a sufficiently practical state to solve just exactly the problem now before us in Washington."

Mr. G. M. Phelps, by invitation of the President, here set in motion the Davenport model electric railway some fifty-five years old, and he stated the circumstances under which it was recently discovered by Mr. F. L. Pope and rescued from oblivion and the dust heap. Both Mr. Phelps and President Madden drew attention to the dramatic contrast presented between this old model of a brave and struggling inventor, who was far ahead of his age, and the latest development of electric traction, exemplified in the model of the underground electric road in London, standing on an adjoining table. President Madden then introduced Mr. Louis Sterne, C. E., to speak for this latest development.

Mr. Louis Sterne, C. E., said: The common desire in all cities is the rapid communication from residential to business centres, and thus to relieve the already overcrowded thoroughfares and existing means of transit, as population grows in any great metropolis with commercial and industrial prosperity, such as London and New York.

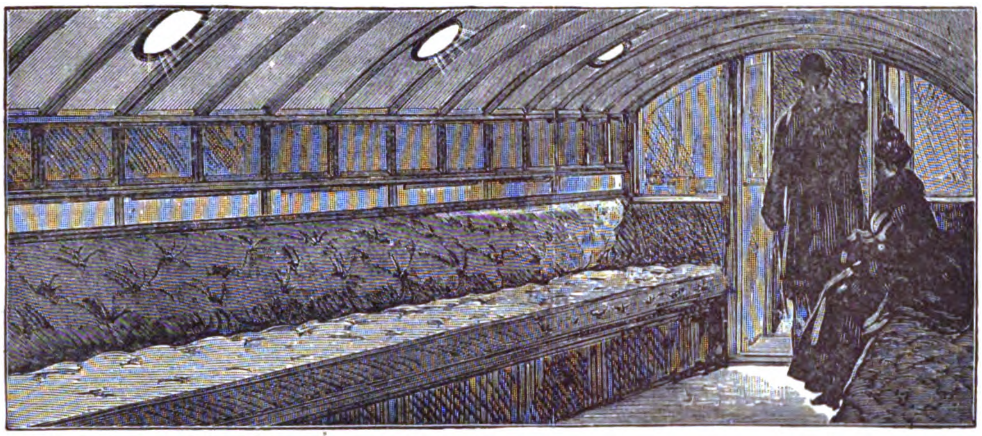
New York differs essentially in many particulars from other great centres of population, although the common desire to be quickly transported from place to place is univesal in every city; but the configuration of New York city concentrates the pressure of the greater portion of the population, especially as the business portion is at the lower end of the city, and thus compels the movement of the larger part of its male population in opposite directions once in each day. London has always been more favored in this respect as it has had an excellent omnibus service which has trebled in point of numbers, and has numerically increased in its transport of passengers in exact or even greater proportion. The cabs in London, with the strict enforcement of legal regulations and the low rate of fare, have also contributed largely towards the conveyance of persons from place to place. The pressure in London, therefore, is not so great, although they have made the advance over New York in seeking to solve the problem of rapid transit.

Two tunnels were built in London, one by Mr. Brunel in 1860, and one by Mr. Greathead in 1868-9; the former fell into disuse until the Metropolitan Railway used it as the means of reaching the Surrey side of the river, and made their terminal at New Cross, some four miles from the mouth of the Brunel tunnel. The Tower subway, designed and built by Mr. Greathead and Mr. Barlow for omnibus traffic by gravitation, is used only for foot-passengers to the extent of about 100,000 a month. The original plans were never carried out for want of funds.

The next approach to a tunnel was the well-known Metropolitan Underground, and since then the District Metropolitan, now known as the Inner and Outer Circle, a small portion of which has cost as much as at the rate of $30,000,000 per mile. These have been supplemented to a very considerable extent by the main lines of railway, both north, south, east and west of London, having their terminals as near the business centres as possible, and with the running powers over the Metropolitan Railway, carrying an immense number of passengers from the suburban districts of London. In addition to this, we have in the city of London between 15,000 and 16,000 cabs, carrying passengers at 12 cents per mile.

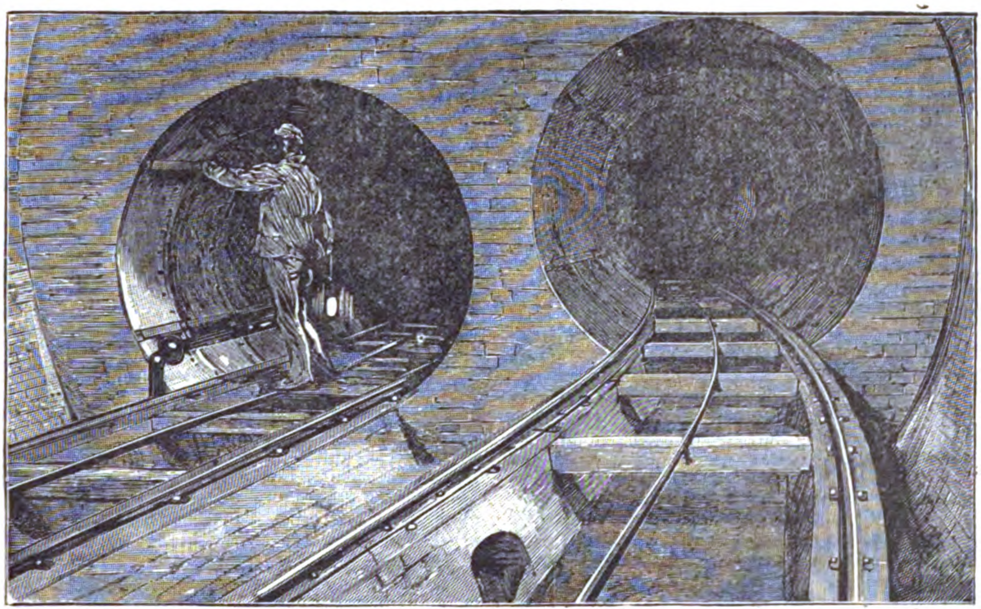
Street cars have also been laid down in the streets of London in the last 20 years, but these are not permitted to enter beyond what is technically known as the City limits. Thus their usefulness for a continuous journey across or through the metropolis has been minimized.

Underground Railways.—Many attempts have been made by the Metropolitan and District Railways, and also by private corporations, as promoters, for increased facilities in London, but the moment they showed on the walls of the committee rooms, either in the House of Commons or in the House of Lords, the old system of disturbing streets and vested rights and properties, with the old method of traction involving asphyxiating air, brick porous lining, and the smoke and gases of the engine, the bills were thrown out and never came beyond the first committee.



Passenger Car, City and South London Railway.

Subway work ceased, until cable traction suggested to Mr. Greathead the possibility of making his system of deep tunneling successful for rapid transit. Mr. Greathead's name is now as well known in Great Britain and is as closely associated with deep tunneling as the name of Mr. Edison is associated with electricity. Although the cable suggested the possible traction in deep tunnels, electricity solved this problem for Mr. Greathead, as neither safety nor speed in cable traction can compare with that of electricity, and the iron lined and cemented tunnel lends itself perfectly to electric traction. (The tunnels of the City and South London road are shown in the accompanying illustration.)



Tunnels of City and South London Railway.

The American people will not be slow in adopting the improvement thus developed in Great Britain, and which will make underground means of transit as safe and as healthful as the surface roads have been until now; and will also make these substructures in all cities in the United States as important an element as the elevators have proved in utilizing the upper streets, and practically doubling the area of the densely populated districts of every great city in the United States. You have not lost much time in adopting these improvements in the mode of rapid transit underground, and you probably have profited by waiting until the advance came to you from Great Britain. Just as you have benefited by postponing the building of a United States Navy and naval armaments, you have been enabled to take advantage of all that has been done, and adopted the best design of the many cruisers which formed the experimental period preceding the building of your navy, and thus saved many millions of dollars and much vexation; and it may not be long before Great Britain will have to look to the United States for the adoption of many improvements made here.

You are fortunate in having such an earnest and able commission appointed by your chief magistrate—an appointment confirmed by the State, and with full powers to give the necessary facilities for rapid transit in New York, and for New Yorkers especially.

Mr. Sterne added that the City and South London road in its first six weeks had carried 1,100,000 passengers, and had run about 11,000 trains with only 18 failures to make schedule time. The road is now to be extended northward, from the city to the Angel at Islington, and would be crossed at right angles by a 12 mile tunnel electric road running along Oxford street, Holborn, Newgate street, Cheapside and Cornhill.

Mr. Sterne illustrated his remarks by frequent references to a large map of London and a large model of a section of the Greathead tunnel as used in the City and South London electric railway.[1]

Mr. H. H. Neill, of the *Commercial Advertiser*, spoke of the relation of the New York press to the city's rapid transit problem, presenting in a most entertaining manner the "momentarily popular," the "probably successful," and the "everlastingly right" aspects of the question. He argued, with much force, against any attempt to deal with the question other than by a solution that would be permanently effective and adequate.

---

[1] See for full description of the electrical plant, The Electrical Engineer of Nov. 26, 1890.

Mr. Sterne: I would like to say that I forgot, during my remarks, to state that the Hudson River tunnel is now being built on the Greathead system, and we are advancing there at the rate of ten feet a day. The last two or three days we have really made 15 feet a day.

Mr. T. Graham Gribble spoke on Rapid Transit in London and New York, with special reference to the topographical characteristics of the latter city. He described briefly the duplex railway system, the adoption of which, as a means of solving the rapid transit problem, he recently advocated before the commissioners.

Mr. W. J. Richardson, secretary of the American Street Railway Association, said: I received this morning a letter in which occurs this sentence: "Boston, Albany, Washington, Brooklyn, New York and London will be spoken for, and what I want is to leave the rest of the country to you." There is nothing small about the man who includes within the confines of the United States the City of London. (Laughter.) There is nothing insular about Mr. T. C. Martin. Indeed he can only be adequately compared to the telephone people who want the earth, or rather, let me say, he is like the generous electrical street railway man who is willing to divide the earth with everybody. (Laughter.) Mr. Richardson then spoke eloquently of the good work that street railway men were doing in their respective communities.

Mr. Charles E. Emery, the distinguished steam engineer, said: The relations of the electrical systems to steam settle themselves by the facts. We may put down a cable running through a groove, but at the end of it we have a steam engine, a boiler, and a place to burn the coal. We have overhead a wire which the trolley presses; but at the end of that is a dynamo, the engine, and the place to burn the coal. As yet we have no good pyromagnetic machine, and so long as you must burn the coal and make the steam, the steam engine directly applied will, for very long routes, take the lead. The locomotive is not as economical as the triple expansion engine, to be sure, and you can run the dynamos with triple compound engines and get down to 15 pounds of water per horse-power per hour, and coal proportionately; while the locomotive will take 24 to 26. But you have first this conversion into electricity in the dynamo, and the conversion of the electricity into power in the motor, you have a double loss, and if you get 75 per cent. when you get through, you have done well. It will run down, undoubtedly, in the neighborhood of 50 or 60 per cent. when you average up. So that the gain you get by the triple compound engine is lost by the necessity of going through so many operations before you get the power. Now, you are only even. Therefore it seems there is a chance for electric motors even on railroads of considerable length. No. You are handicapped again by the necessity of having these electrical conductors, and the farther apart the stations the larger the conducting wires must be, and therefore it does not seem feasible. But it does seem that the steam engine directly applied, for roads of considerable length, will hold the lead for a considerable number of years.

Speaking of the plan which seemed to be the best adapted for rapid transit in New York, we come back to the necessity of having four tracks on each main line, one on each side of the city. We need the double line for four tracks, and where shall that be put? New York needs more through streets from the lower to the upper part of the city. A plan was thought of to run through Elm street. No matter where it is put, that street should be run through. Then, when the new street is opened, the excavation could be carried down to the depth required to put in four tracks. In connection with that there should be a surface railway above. That street should be wide enough, if practicable, to put a wall at each side of two central surface tracks and let the electric cars—for they would be electric cars—run there. You could run the local stations to a greater distance, perhaps a mile, or even three-quarters of a mile might be a better compromise, and then the express stations two to three miles. Then you would have rapid transit.

Unfortunately, gentlemen, you have all to use steam engines as yet. We therefore consider that steam is a necessity of the case, but that on account of the losses in small motors, on account of the gases which accumulate in the tunnels, the electric motor has solved the difficulty of running through places where steam cannot go. Therefore, while I quite agree with all here present as to the value of this system, it takes its place only as one of the many means which we have at our command to solve the greater and broader problem. (Applause,)

Mr. Edward Weston said:—I shall not attack the problem of rapid transit from what I should strictly call the point of view of engineering difficulties as separated from the electrical difficulties connected with it. I take it for granted that the engineering difficulties can readily be surmounted; that they are not very serious in character outside of the question of cost. Many years ago Brunel designed and constructed the "Great Eastern." You know how much trouble that steamship gave the company which was organized for building it. Considerable litigation sprang up in consequence of those difficulties, and during some of the litigation Brunel was put upon the witness stand and was considerably annoyed by the questioning of the counsel on the opposite side who twitted him upon his failure to successfully launch the ship without wrecking the company. One of the lawyers who was somewhat brighter, apparently, than the rest, asked Mr. Brunel some very sharp questions in regard to the "Great Eastern," and not getting very satisfactory replies, he suggested to Mr. Brunel, "I suppose you would not have any hesitation about building a tunnel from here to China." Brunel instantly replied, "No, sir; I would not hesitate about it one moment if you would not hesitate about raising the money to carry it through." In reality that was the much more difficult problem. That is largely the question in respect to rapid transit. We are located in a city where property values are very high. We must acquire the right of way for the passage of our trains for the accommodation of the public at large. Having acquired the right of way, the problem falls either upon the mechanical engineer who would take up entirely the old mechanical means of transmission, or upon him and upon the electrical engineer. In the latter case the responsibilities would be divided, the mechanical engineer taking care of what may be said to be the mechanical part of the business and the electrical engineer the electrical part. I shall dismiss the mechanical engineering branch, conceding that that can readily be overcome, and consider only the electrical engineering difficulties in the way. Mr. Emery has said that for the general purposes of carrying of passengers long distances steam takes the lead. It does to-day unquestionably. Does it necessarily follow that it should take the lead, because at the present moment we have to depend upon steam for the generation of the energy that we require to propel our electric vehicles? I do not think so. I think there lies a very grave mistake. The steam engine is an exceedingly inefficient means of transforming the energy derivable from the coal into available power or for doing useful work. Therein our hands are tied to a large extent and when it is considered that the best of our steam engines to-day do not yield us over about 10 per cent. of the actual energy of the coal, you can appreciate the unfortunate position of electrical engineers. Looking at the other side of the problem, how much that impresses itself upon us who have given steady attention to the thing, is very remarkable indeed. The dynamo can be made to-day to yield 98 or 99 per cent. of the energy expended upon driving it in actual electrical energy. Of that, 94 or 95 per cent. can, under proper design, be again utilized in the form of electrical energy. That is, it can be delivered out. Now, taking into consideration the extreme difference between the steam engine and the dynamo, and notwithstanding that the motor is not of the same efficiency as the dynamo, I venture to say that that is entirely a mistake. Whatever the generator will do in the shape of efficiency, that the motor will do. If we do not do it it is because we do not carefully study the problem or we are unwilling to spend more money to secure the results. But, the question as to the efficiency of these two systems, that is the efficiency of the motor and the efficiency of the generator as compared with the efficiency of the steam engine is not entirely one of the prime motor. It is another thing. In the locomotive we have to deal with a very different problem from what we have to deal with in the electric motor. In the electric motor the efficiency does not decrease very perceptibly with a reasonable decrease in size of the motor. In the steam engine, on the other hand, it does decrease with a reasonable decrease in size. Small electric motors can be made of nearly the same efficiency as larger ones. Now, such being the case, small motors applied to the axles or with their power diverted to the axles of the cars in such a manner as to eliminate all loss between the motor and the cars, will yield vastly greater results and better results than a single steam engine located at the head of the train. I think Mr. Sprague, some years ago, considered that question and pointed out the vast superiority of the electric system in efficiency as compared with the steam system when it was taken into consideration that each car had its unit motor and that the tractive force of the whole train was distributed, in about proportion to the actual load on the respective parts of the train. The tractive force in the case of a steam locomotive must all be put in the locomotive. We all know how many tons have to be put on a locomotive in order to get that tractive force, and how far that may be reduced, and how far the efficiency of the electric system may be made to exceed in general that of the steam system, will be better understood when that question is more thoroughly experimented on and studied than it has been so far. It does not follow by any means, that we must have a less efficiency by the intervention of an electric motor. On the contrary, it may be proved, and I think will be proved, that the electrical system will be more efficient than the steam system as generally employed.

In considering the question of what is the best means of rapid transit for a city like New York, we have a number of problems to deal with outside of the question of first efficiency or economy. There must be convenience, quickness of stopping and starting, and everyone will concede that the lighter the parts that are to be moved, the quicker we can stop and the quicker we can start, the less wear and tear, the less strain on our apparatus and generator. Consequently, the electrical system there should possess an enormous advantage over any steam system by reason of the very fact that from the lighter loads and the lighter weights you have to carry in proportion to the power developed, you could stop and start vastly quicker without injury to the machinery. Then, again, in the electric motor we have something entirely different from what we have in the steam engine. We have no reciprocating parts, but continuous rotary motion. The strains are all tangential, and that ought to aid greatly in running and maintenance. The electric motor of to-day is not what the electric motor of a few years hence will be. To-day we are struggling with difficulties connected with the commutator end of the line, which has been the great bugbear of all systems of electric railroads. Commutators and brushes require more care, outside of gearing connecting the cars, than anything else we have to deal with. They are the weakest spot in the motor and they are the weakest spot in the dynamo. The question arises, Can those difficulties be overcome? I think they can. But if they are not overcome, are they not already sufficiently overcome to warrant our placing our reliance upon such a system of transmission? Well, the railroads we have already built, I think, are a sufficient answer to that question. Much of the railroad work that has been done here has been experimental in character. It must continue to be experimental in character for some time to come.

In connection with the motor we are laboring under very serious difficulties in regard to regulation. In the electric motor we cannot do just exactly as we do in the steam—adjust our point of cut-off so as to secure the best results with a given load. With the steam engine you can do that to a certain extent with a given size of engine. With the electric motor, unfortunately, we cannot do that at present.

We have to govern our motors by varying the resistance in the circuit, which means loss, necessarily, because that resistance has to be overcome to some extent by the current passing through it or by reducing the intensity of the field magnetism, which also means loss. Now that is unfortunate; but is it necessary? I think not. The ideal electric motor for the transmission of power would be a motor running at a continuous and uniform speed and with a variable gearing, giving the motor the advantage of power when the car was first started. That we have not exactly reached. You all know that the man in front of the car stands with a regulating device in the cab. When he wants to change the speed of his motor he moves a switch or arm around which adjusts the current flowing through the motor. Now, as a matter of fact, the motor should adjust the current itself, and not the man, and the speed of the motor should remain absolutely constant, while for regulation between the motor and the gear on the driving wheels, you should depend on varying the mechanical advantage entirely.

The needs for such a system as we have to deal with here in the city of New York, where enormous amounts of power would be required, are not by any means easily solved. I do not think any direct current system would entirely answer the purpose without a large number of stations and comparatively small units of power. The difficulties in this respect, however, are not the same as we have to deal with in the transmission of currents of energy for electric lighting purposes. In such a system as is proposed here, the pressure can be largely increased without very great danger or without the limitation imposed by incandescent lamps or other things which we have to deal with, it being mainly a matter of insulation and proper construction of the apparatus. But even under those circumstances, considering that you may lay out a plan or system with great care for insulation, leaving a sufficient margin or factor of safety for all occasions, it does not seem to me very possible or probable that we could do that with a few central stations. We should have to have quite a number unless some system of conversion from high potential to low potential was adopted. During the last few years considerable development has taken place in the art of electric lighting in certain lines, which I may briefly refer to as the alternating current system. That system has extended over a very wide area and has come into quite extensive use and has grown very popular indeed. It is now well understood that that system does not bend itself very well to the transmission of power—that there are grave difficulties to be overcome, in connection with the motors. The coefficient of self induction, or the kick back, so to speak, of the motors themselves, alone interposes a great obstacle to the output per unit of weight. But there is no reason in the world why continuous current converters should not be made vastly to exceed in efficiency the alternating current under all conditions of load, which would enable us to distribute currents of enormously high potential over very long lines by means of comparatively small conductors. It seems to me that herein lies the future success of such a system as has been discussed here to-night; that if we expect to reach high speeds and get economical service we cannot hope for a distribution based upon the direct application of the current, but upon some modification of it through a secondary converter by direct current conversion.

As to what can be done here in regard to rapid transit, or anywhere else, under conditions most favorable to it, I take it for granted that none of us know. It can only be found out by actual test. There is no question about that. That the return will far exceed our most sanguine expectations in that direction I am sure. With skill, ingenuity and care, there is no question in my mind about the development of rapid transit in this city or any other by means of electricity.

Mr. Weston closed by an interesting reference to the near probability of obtaining effective pyromagnetic generators, and pointed out that current had already been successfully derived from the oxidation of carbon without the application of heat. He closed with the remark: "It does not seem to require very much to carry us further along to producing the thing itself. Whatever is done in that direction will come right into play in connection with the future rapid transit system of New York and the world outside."

The meeting then adjourned.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER 150 *Broadway, New York city.*

PLANT EFFICIENCY WITH HEDGEHOG TRANSFORMERS.

Mr. Stanley's paper in THE ELECTRICAL ENGINEER of December 10, calls for a reply from me. Mr. Stanley divides transformers into two classes, the closed circuit or "American" type, and the open or Gaulard and Gibbs type, the hedgehog being included in the Gaulard and Gibbs. I do not quite understand why the closed circuit transformer should be called American; it was not first invented by Mr. Stanley, nor was it first made in America, and it was already well known in 1885. This point has, however, nothing to do with the main subject of Mr. Stanley's paper, except in so far as it invokes national prejudice in favor of the closed circuit.

He says that in 1885, before adopting the closed circuit transformer, he considered the merits of the open circuit type, including the hedgehog. The hedgehog transformer, however, was not invented in 1885. Mr. Stanley assumes that the primary current of the hedgehog transformer does not decrease with the load, or that it decreases, at most, 20 per cent. This may be the case with the early form of Gaulard and Gibbs transformers, but is not true of the hedgehog. The exciting current at no load is about one-third of the full load current. Taking, now, Mr. Stanley's example, we may take a station with the full load output of 10,000 lamps and 10 engines and dynamos. Taking 95 per cent. as the full load efficiency of the transformers, whether open or closed, and omitting loss in leads, we have 525,000 watts supplied to the terminals of the dynamos. Assuming efficiencies of 90 per cent. for the dynamos and engines, we have 583,000 watts supplied to the pulleys and 648,000 watts indicated. If all the lamps are turned out, one engine and dynamo can run all the closed circuit transformers. There is then a waste of 25,000 watts in the iron, the waste in copper being taken as inappreciable; there is a loss of 5,800 in the dynamo and 6,500 in the engine, making a total waste of 37,400 watts.

Taking, now, the case of the hedgehog. At no load the loss in iron is about 5,000 watts, and three dynamos can supply the exciting current. As very little power is needed, it is not necessary to run three engines. Nine engines and seven dynamos are, therefore, shut down altogether, and two dynamos are left running with the engines, uncoupled by friction or other clutches, and one engine supplies the power. We thus have one engine driving one dynamo directly, and two other dynamos running loose as motors and supplying the exciting current. The total loss is, then, 5,000 watts in the iron of the transformers, 17,400 watts in three dynamos and exciters, and 6,500 loss in one engine, making a total of 30,000 watts. So, even in this clumsy way, the loss in the hedgehog type comes out less than in the closed circuit type, instead of 7.6 times as great, as Mr. Stanley makes it. I must point out, however, that if the transformers had to be run all day with no load, a 50,000 watt engine would not be used to drive, as only 5,000 watts are used in the transformers.

This method is only one way of running open circuit transformers. We have not yet had any trouble from exciting current, and when we do, we will merely provide condensers to supply the exciting current. It is then necessary in the previous example to run one engine of 6,200 watts, and one dynamo giving 5,000 watts on the terminals. The loss with the closed circuit transformers thus comes out six times as great as the loss with the hedgehog, instead of being about an eighth, as Mr. Stanley makes out. Even this comparison is not quite fair, as the efficiency of 95 per cent. for the closed circuit is higher than is generally obtained in practice. The Westinghouse Company, for instance, advertises the efficiency of three leading American makers as below 90 per cent.

They except their own, but they may be biased with regard to it. There is no reason why they should have any monopoly of high efficiency in closed circuits, as any other maker can use good iron and follow the principles laid down in my British Association paper. I am quite aware, of course, that a scientifically designed closed circuit transformer can give 95 per cent. efficiency; but advocates of closed circuit transformers should do me the justice to admit that this high efficiency is not due to them. Until my paper was read at the British Association, in 1888, little was thought of the loss in iron. I there showed how closed circuit transformers should be designed to give 95 per cent. efficiency; and since then makers have reconsidered the proportions of the iron and copper in their transformers. As far as I know, nothing had been said before about proportioning the iron so as to get small loss by hysteresis. The high efficiency closed circuit transformers have been produced by following the lines indicated in my paper. I am, therefore, hopeful that electricians will eventually go still farther, and fully realize the value of the hedgehog transformer.

JAS. SWINBURNE.

Wimbledon, England.

THE MOST ECONOMICAL ARRANGEMENT FOR ELECTRO DEPOSITION.

In reply to Mr. C. O. Mailloux's remarks under the above heading, appearing in your issue of Feb. 18, I must acknowledge that I can still see no advantage to be derived from his "live" resistance, which must vary with every change of current, instead of representing the term counter-electromotive force in its simplest and true light—a constant. The method suggested by him in obtaining his "live" resistance, in order to get the term ε in the equation $E = C(R + r) + \varepsilon$, is impracticable. He says: "From the potential difference at the terminals of the vat and the current passing through the vat, we obtain $\frac{E}{C} = R + \rho$. We then measure the ohmic resistance R and subtract its value from $(R + \rho)$; or, $\frac{E}{C} - R = \rho$." In electrolytic refining of copper, $R = .001$ ohm, is a large value for the resistance of a vat. Measuring such a resistance by a resistance method without the most perfect and delicate laboratory instruments, perfect contacts and calibrated connection pieces, is, of course, out of the question, leaving out of consideration the effect of even a minute electromotive force upon the measurement of so small a resistance. Besides, the conditions under which the observations were made would not be the same.

Mr. Mailloux calls attention to the "almost humorously" high voltage which I mention (about 75 volts). I do not know to what plant he refers when he says that, "The presumably oldest and largest copper refining firm in this country has for years used, and, so far as is known, is still using, machines of over 4,000 amperes with an E. M. F. of 15 to 20 volts." The largest plant in this country of which I have any knowledge refines over 17 tons of copper per day, using an E. M. F. of 135 volts. Another large copper refinery, having a generator capacity of over 140 kilowatts has 60 volt machines. Of course with small plants of only 35 or 40 vats it is impossible so use anything but a low voltage, on account of losses by the decomposition of water.

Since the plan which I propose—of using the moderate voltage of "about 75 volts" in large plants and connecting the vats in single series—has been so attacked, I have taken the trouble to look up the latest practice abroad. The latest London *Electrician* (February 6, 1891) speaks of one of the dynamos used in the new Elmore Works, near Leeds, as having an output of 750 amperes at 50 volts, and, nothing being said to the contrary, the others have presumably the same voltage. I also find in Gore on "Electrolytic Separation of Metals," edition of 1890, p. 182: "The arrangement of a number of small vats in series is preferable, because with a small number of large ones in series and a current of low electromotive force, any increase of resistance in the vats, or any cross circuiting has much more serious effects than with a larger number of vats and a current of higher electromotive force." It seems to me that this stands to reason. Also in other places, the electromotive force in use in the North German Refinery, Hamburg, is given as 54 volts; at Pembroke, England, 110 volts; at Ponte Sto. Martino, Piedmont, 120 volts, and so on. From the above I think that the latest, and presumably best, practice will be found to uphold my ideas.

I regret that Mr. Mailloux should have thought that I did not give him due credit. It was certainly through no intention on my part to underestimate his interesting articles, and I treated, naturally, of the points on which I disagree with him.

GILBERT WILKES.

NEW YORK, Feb. 20, 1891.

W. A. CADUGAN, of the Edison Company, is constructing several plants in the southern part of Pennsylvania, with headquarters at the Martin Building, Pittsburgh, Pa.

Home Correspondence.

BOSTON.

An Underground Road for Boston.—A Rapid Transit Commission Wanted.

AT the State House a continued hearing was given to Mr. H. C. Spaulding for authority to construct an underground railway in this city. Mr. Woodward Emery, in behalf of Mr. Spaulding, stated that the object of the road was to connect the railway stations of the city rather than to take care of the outlying sections, so that the surface roads would not be much interfered with.

The subject of the regulation and control of electric wires was also discussed before the committee on mercantile affairs. Representative Stearns, of Salem, spoke in favor of having these wires under the control of proper authorities. A bill was presented to the committee providing for a board that should have control of the use of electric wires, the granting of locations and licenses, and charging fees for each new pole erected.

At a meeting of the Board of Aldermen, a statement was received from Inspector of Wires Brown S. Flanders, showing that $11,707.07 is needed for salaries from Dec. 1, 1890, to May 1, 1891, and that he has only $849.70 for the current running expenses during the same time. This makes the $12,556.77 that was transferred to his department from the fire department.

At a meeting of the Common Council the aldermanic order was passed that the mayor be requested to appoint three persons, who, with the mayor and city engineer, ex-officiis, shall constitute a commission to consider the subject of rapid transit and quicker communication between the city proper and the outlying districts and suburban towns and cities.

BOSTON, Feb. 28, 1891.

PITTSBURGH.

New Plant for the Allegheny County Light Co.—The Schenley Park Electric Railway.

THE power house of the Allegheny County Light Company, which is now situated in Virgin alley, this city, will shortly be removed to a more convenient location. The company recently purchased a site on Etna and Twelfth streets, a part of the Bradley estate, and here a new plant will be immediately erected. The new site is three hundred by one hundred feet, and it will give the company an opportunity to put up a building that will hold enough electrical machinery to make it probably the largest electric lighting plant in the world. The company has for some time been in very close quarters, in the old power house. The enormous demand made upon its capacity caused the building to become very crowded. The Allegheny County Light Company operates the Westinghouse alternating current system and has now a capacity of 35,000 incandescent and 1,000 arc lights, and if the company were able to satisfy the demand made upon it by the public, it would be necessary to increase the plant at the rate of about one thousand lights a month. This, however, is impossible under the present circumstances, because the old plant will not hold any more apparatus conveniently. In the new building, however, the company expects to be able to place enough electric lighting machinery on one floor to furnish over 100,000 16 c. p. incandescent lamps. The old buildings are now in the market, and it is expected that the removal will have been completed by next October.

PITTSBURGH, Feb. 27, 1891.

College Notes.

COLUMBIA COLLEGE.

DR. M. I. PUPIN, Instructor of Mathematical Physics in the Department of Electrical Engineering, of Columbia College, began on Feb. 21st, a course of university lectures "On the Principle of the Conservation of Energy and its Application in Physics and Chemistry." These lectures are delivered on Saturdays, from 11 to 1.

KIND WORDS FROM GERMANY.

A leading American and German electrical company with headquarters at Hamburg, writes us as follows from that city, under date of February 9, with regard to their subscription, which they had allowed to lapse through oversight: "We have not received our copy of your esteemed journal for some time, and would like to know whether our subscription has run out, or if some mistake has occurred. In any case, please continue where you left off, as we regard your journal the most valuable of all the technical journals in this office of which we have very many, and in five or six languages."

Reports of Companies.

MATHER ELECTRIC COMPANY.

At a meeting of the stockholders of the Mather Electric Co., Manchester, Conn., the following officers were elected: President, H. G. Cheney; vice-president, M. S. Chapman; secretary and treasurer, R. Cheney; general manager, N. T. Pulsifer; electrician, W. A. Anthony.

SOUTHERN MASSACHUSETTS TELEPHONE CO.

At the annual meeting of the Southern Massachusetts Telephone Co. the following officers were elected: President, C. W. Clifford; clerk and treasurer, S. Ivers; directors, C. W. Clifford, O. P Brightman, W. Clifford, M. Rotch, M. E. Hatch, S. Ivers, W. H. Forbes, T. Sherwin, S. W. Knowles.

An annual dividend of 8 per cent. is now payable.

THE EICKEMEYER-FIELD CO.

The above company has been formed with a capital stock of $1,000,000. Rudolph Eickemeyer is the president; S. Shethar, vice-president; E. A. Nichols, treasurer. The company proposes building electrical apparatus and appliances under the patents of Rudolph Eickemeyer and Stephen D. Field. The Eickemeyer factory is now being enlarged for the work to be done.

THE WIDDIFIELD BRAKE.

Mr. Watson P. Widdifield, of the Widdifield Electric Brake Co. (Limited), Toronto, Canada, having sold his U. S. patents, has gone to Europe to dispose of his patents in Great Britain, France, Germany, Spain, Italy, Belgium, Austria-Hungary, India and Russia.

ELECTIONS.

The Greenfield, Mass., Electric Light Co., at its annual meeting, elected the following officers: President, H. W. Warner; secretary, C. H. Keith; treasurer, F. E. Pierce.

The Webster (R. I.) Electric Light and Gas Co. has elected the following officers: N. T. Hurlburt, president; L. E. Pattison, secretary; J. S. Gould, treasurer; with a board of five directors.

Canastota, N. Y.—The stockholders of the electric light company have elected W. H. Patten, secretary and treasurer, to succeed W. H. Tuttle. George Tibbits was elected superintendent.

Brattleboro, Vt.—The annual meeting of the Vermont International Telegraph Company was held recently at St. Johnsbury. These officers were re-elected: President, Franklin Fairbanks; secretary, George W. Hendee; superintendent, E. A. Silsby.

Helena, Mont.—At a meeting of the board of trustees of the Helena Electric Co. the following officers were re-elected: President, C. W. Cannon; vice-president, H. M. Parchen; secretary and treasurer, H. L. Walker.

Meadville, Pa.—At the annual meeting of the People's Incandescent Electric Light, Heat and Power Co., Meadville, Pa., the following officers were elected for the ensuing year: President, Dr. Cyrus See; vice-president, C. Fahr; secretary, F. R. Shryock; treasurer, J. Reitze, Jr.

Utica, N. Y.—The stockholders of the Electric Light Company have elected the following trustees: H. D. Pixley, R. T. McDonald, W. E. Lewis, Joseph F Blaut, T. Solomon Griffith, H. M. Schench, M. J. Brayton. The trustees elected the following officers: H. D. Pixley, president; R. T. McDonald, first vice-president; W. E. Lewis, second vice-president; M. J. Brayton, secretary and treasurer.

STOCKS AND BONDS.

Jenkintown, Pa.—The stockholders of the Jenkintown, Pa., Electric Light Company, are considering the advisability of increasing the capital stock of the company from $40,000 to $100,000.

Worcester, Mass.—A mortgage for $350,000, given by the Newburyport and Amesbury Street Railway Company, to the International Trust Company, of Boston, has been recorded in the town clerk's office, in Merrimac.

DIVIDENDS.

Eastport, Me.—The Eastport Gas and Electric Co. has declared and paid a dividend.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the Council, on February 24, the following gentlemen were elected to associate membership:

Anthony, Watson G.—Assistant Electrician. The Okonite Co., 32½ Webster street, Newark, N. J.
Gordon, Reginald.—Assistant in Physics, Columbia College, New York City. Residence, 76 Park avenue.
Laudy, Louis H.—Assistant in Applied Chemistry, School of Mines, Columbia College, New York City. Residence, 289 West Fifty-second street.

The evening was devoted to a paper by Mr. O. T. Crosby, of Boston, on the results of his work in electric traction at 120 miles an hour, with the Weems system, at Baltimore. There was a brisk discussion. Mr. F. L. Pope described and exhibited the model electric railway, recently found by himself during his researches for the biographical sketch of Thomas Davenport in The Electrical Engineer. The attendance at the meeting was very large.

CHARLES E. EMERY TO LECTURE BEFORE THE NEW YORK ELECTRICAL SOCIETY.

The next lecture before this Society will be given at Columbia College School of Mines, on the evening of Friday, March 6th, by Charles E. Emery, Ph.D., the well known engineer, on the subject of "The Utilization of the Forces of Nature." This lecture will be remarkably well adapted to interest both a popular and a technical audience. Starting with a brief classification of the various known forces, the speaker will advert to the various familiar phenomena which produce currents of air and of water; refer to the storage of energy in fuel, due to the action of natural forces in former ages; illustrate on the screen a tornado, a lightning flash and the effects of winds and storms on trees and buildings; show various views of wind mills, including examples of those used for draining the Holland polders, contrasted with those of American construction, and describe briefly the principles of regulation of various wind mills. The subject of water power will be treated exhaustively, with illustrations of different kinds of water wheels, notes as to the relative efficiencies, an explanation of the principles of the turbine, interspersed with views of waterfalls, glaciers and references to important works and means employed to transmit the forces and utilize the same at a distance. The methods of utilizing the energy stored up in fuel will be illustrated by several examples of land and marine steam engines and of steamers of the merchant and naval marine. It is proposed to curtail the remarks in relation to the application of electricity as being already familiar to the audience, and instead thereof to discuss the relative efficiencies of the different means available for utilizing the energy of natural forces and show the applicability of each for particular purposes. The evening, in short, promises to be one of the most useful and interesting ever enjoyed by the Society.

Appointments, Etc.

Mr. J. A. Smiley has succeeded Mr. O. B. Conlin, as superintendent of the Electric Light Company, of Orangeburg, S. C.

Mr. T. C. Frenyear has accepted a position with the Edison General Co., and will represent it in New York State, giving special attention to the railway department.

Mr. M. D. Law, late of the Denver, Col., Consolidated Co., and of the Brush Co., of Philadelphia, has been placed in charge of the arc light department of the Edison machine works, at Schenectady, N. Y., where he will have charge of the output, &c.

Mr. A. P. Wilkes has been appointed superintendent of the electric lines in St. Paul.

Electrician Wells has been appointed superintendent of the Auburn City Railway Company, of Auburn, N. Y.

William E. Smith, of Allentown, Pa., has been appointed assistant to Manager Lerch, of the Reading telephone district.

U. S. ELECTRIC RAILWAYS CO.

Mr. R. S. Brown, the agent of the railway department of the Westinghouse Co. in New England, has just closed a contract for the Biddeford, Saco and Old Orchard Beach road. The U. S. Electric Railways Co., of this city, will do the construction.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEB. 17, 1891.

Accumulators:—

Secondary Battery, A. M. F, Laurent-Cely, T. A. Timmis, 446,527. Filed Apr. 8, 1890.

Has for its object the production of plates of much less density and more storage capacity than those previously made.

Alarms and Signals:—

Annunciator, J. H. Elfering, 446,641. Filed Apr. 24, 1890.

Relates to improvement in that class of hotel annunciators in which the room from which a guest is calling is not only located, but also the specific want of the guest made known in the office and visually displayed there until it has been noted by the clerk.

Electric Call-Bell, D. H. Rice, 446,713. Filed Nov. 16, 1881.

Consists in applying to a Currier bell an automatic circuit breaking device working in the time of the vibration of the hammer of the bell, and so adjusted as only to be set in action when the bell hammer has reached its amplitude of vibration.;

System of Electric Calls, J. B. Currier & D. H. Rice, 446,732. Filed Nov. 18, 1888.

Invention consists in providing a circuit-breaking calling mechanism with a shunt circuit and a key or other like device to send a current through the magnet and around the circuit coil, together with other details.

Clocks:—

Electric Regulating-Clock, D. Van De Plancke & G. Van De Plancke, 446,801. Filed May 21, 1889.

Invention consists of a new system of electric regulating for clocks, in which the instantaneous closing and breaking of the electric circuit has the double effect of sending intermittent currents to different receiving dials and at the same time winding the regulator itself.

Dynamos and Motors:—

Commutator and Brush, H. F. Parshall, 446,536. Filed July 30, 1890.

Claim follows:

In a reversible electrical machine or motor the commutator provided with bars or sections with wires of the armature, in combination with a pair of brushes arranged thereon with opposite inclinations and making sliding contact with same bar or section of the commutator.

Electric Fire-Engine, M. W. Dewey, 446,703. Filed July 7, 1890.

Has for its object to electrically propel an electric fire engine to and from the fire so that it will not be necessary to employ horses for this purpose.

Galvanic and Thermo-Electric Batteries:

Battery Compound, W. Wright, 446,544. Filed May 12, 1890.

Has for its object to provide an electrolyte for primary and other batteries, whereby electromotive force of any desired intensity may be secured at a lower cost than has hitherto been obtained.

Pyro-Chemical Battery, J. Blair & A. J. Hunter, 446,727. Filed June 25, 1890.

Invention consists of a cell containing a series of composite plates each formed of an iron plate separated from a carbon plate by prepared absorbent septa or partitions, the chemically active plates being connected by a wire with the chemically passive plates in the successive composite plates in the usual manner; the chemical transfer of the elements being caused by the application of heat.

Lamps and Appurtenances:—

System of Electric Lighting, T. A. Edison, 446,666. Filed June 26, 1882.

Has for its object to produce an efficient means for supplying with current incandescent electric lamps, motors and other translating devices arranged in multiple arc, and for utilizing a current of high tension in the main conductors so as to reduce the investment for copper in such main conductors.

Electric Arc Lamp, J. A. Mosher, 446,459. Filed July 8, 1890.

Details of feeding and braking or arresting mechanism.

Moisture-Protection Hood for Lamps, A. Shillinglaw, 446,477. Filed May 22, 1890.

Detail of attachment and support of hood.

Disc Carbon Holder for Electric Lamps, E. C. Russell, 446,549. Filed May 14, 1890.

The invention consists of a spindle having a screw threaded enlargement and a conical projection and a split thimble, the rear end of which is threaded to fit the screw on the spindle.

Carbon for Electric Lamps, W. H. Burns, 446,660. Filed July 26, 1890.

Claim as follows:

A carbon for electrical purposes composed approximately of 90 parts of triturated, purified maltha coke and 10 parts of semi-liquid purified maltha thoroughly incorporated therewith.

Electric-Arc Light, T. A. Edison, 446,668. Filed Aug. 7, 1882.

Has for its object to produce simple and sufficient means for regulating the feed of the upper or positive carbons in arc-lamps.

Manufacture of Filaments for Incandescent Electric Lamps, T. A. Edison, 416,669. Filed March 16, 1888.

The filament is formed of a number of filaments massed together, the resulting filament being equal in size and mass and integral throughout its entire length.

Detachable Ceiling Block or Bracket for Electric Lamps, H. C. Wirt, 446,826. Filed Oct. 29, 1889.

Relates to electric cut-outs of that class in which a cap or rosette is detachably secured to a base and has for its object to effectively combine with the said cap or rosette a bracket to which one or more incandescent lamps may be secured.

Measuring Instruments:—

Electrical Measuring Instrument, E. Weston, 446,489. Filed Mar. 17, 1888.

Utilizes the principle that when a continuous body of diamagnetic metal is suspended between the poles of a magnet, it finds in the field of force a powerful resisting medium which opposes any motion and speedily brings it to rest.

Electrical Measuring-Instrument, E. Weston, 446,491. Filed May 12, 1890.

Consists of a stationary coil, a vibrating or oscillating coil supported in the field of force of said stationary coil, a means of indicating the extent of movement or deflection of such movable coil, and a spring opposing the motion of said vibrating coil.

Electrical Measuring-Instrument, E. Weston, 446,492. Filed July 1, 1890.

Combines in a measuring instrument a primary conductor, a secondary conductor, and two coils included in said secondary conductor, one of said coils being movable in the field of the other.

Electrical Measuring-Instrument, E. Weston, 446,493. Filed Oct. 14, 1890.

Details of design and construction for measuring the difference of potential between its terminals.

Electrical Measuring-Instrument, E. Weston, 446,494. Filed Oct. 16, 1890.

Potential instrument. Novelty in design and construction.

Medical and Surgical:—

Magneto-Electric Machine, G. P. Clarke, 446,661. Filed Aug. 23, 1890.

Claim as follows:

An electrical casket having in combination with the enclosing case, the main shaft actuating spring or springs. connected armature magnet and circuit breaker, and a permanent hand electrode. The removable hand electrode electrically but loosely connected with the driving shaft.

Metallurgical:—

Amalgamating Apparatus, T. Gemmell, 446,706. Filed Dec. 12, 1889.

Claim follows: In an amalgamator, a mercury holding vessel, a pipe extending within the said vessel to near its bottom to convey ore from a point exterior to the vessel to a point below the contained mercury, the lower end of said pipe being flaring and upwardly turned. A porous cell supported by the upturned portion of said pipe, and an electrolyte and an anode in the porous cell combined with an electric generator and wires leading from the opposite pole of the generator to the anode and the mercury.

Induction Coil, F. H. Brown, 446,780. Filed July 21, 1890.

Consists of a battery combined with an induction coil for the purpose of locating and detecting mineral ores, by placing the discharges of the induction coil in contact with rock supposed to contain metals.

Magnetic Ore-Separator, C. G. Buchanan, 446,767. Filed Feb. 25, 1890.

Claim follows: In a magnetic ore separator a hollow cylinder of alternating segments of magnetic and non magnetic material. A series of electro-magnets arranged to polarize the magnetic portions of the cylinder, and means for reversing the polarity of the electro-magnet.

Miscellaneous:—

Electro-Magnetic Cut-Out, L. Gutmann, 446,515. Filed Feb. 4, 1890.

Has for its purpose to automatically connect or disconnect a dynamo or motor or any other apparatus to or from the main line, but especially when it is in circuit with alternating intermittent or pulsating currents of high electromotive force.

Electric Lock, 446,509, E. J. Colby, Filed May 6, 1890.

For the protection of valuables.

Rheostat, E. Weston, 446,490. Filed Feb. 28, 1889.

Relates to an instrument having for its object the interposition of a desired electrical resistance in a circuit, the determination of a resistance the magnitude of which is unknown, and the finding of the difference of potential between two points of a circuit.

Electric Music-Box, C. A. Hussey, 446,684. Filed Dec. 29, 1888.

Claim 1 as follows:

The combination with a music box comb and a pin cylinder, of an electro-motor for rotating the pin cylinder, a lever controlled by one of the moving parts of the music box mechanism. and serving to operate a circuit breaker or closer, and a cam acting on said lever.

Electric Heater, T. J. Donovan, 446,831. Filed Jan. 20, 1890.

Relates to the heating of fluids and the generation of steam by electricity.

Glassware, X. Zgraggen, 446,590. Filed June 23, 1890.

Claim as follows:

A hollow article of glassware whose interior surface is lined with a compound metallic coating consisting of a chemically deposited metal film next to the glass, and an electro deposit of metal which backs and protects said film.

Railways and Appliances:—

Electric Railway Signal, W. S. Cook & M. C. Cook, 446,546. Filed Nov. 16, 1889.

An electric system of danger signalling for railways whereby the engineer of the train will be notified in time to stop his train before it is too late. Also an improved system of telegraphing or signalling from one train to another or from a train to a station.

Conduit Electric Railway, E M. Bentley, 446,417. Filed Oct. 13, 1887.

Invention relates to electric railways in which the main supply conductor or conductors are enclosed in a slotted conduit and consists in an arrangement of line conductors for switching and crossing.

Electric Line Switch. E. M. Bentley, 446,418. Filed Feb. 15, 1890.

Relates to an overhead line conductor which is divided into sections, and consists of a switch for connecting the sections attached directly to the line conductor.

Contact Device for Electric Railways, E. M. Bentley, 446,420. Filed July 11, 1890.

Adapted to maintain a traveling electric connection with a supply conductor located in a slotted conduit.

Contact Trolley for Electric Railways, J. B. Cahoon and I. F. Baker, 446,428. Filed July 3, 1890.

Provides an automatically detachable contact maker upon a trolley-pole of usual construction.

Electric Railway, N. Siebert, 446,475. Filed May 5, 1890.

Designed to provide a simple means for facilitating the rounding of curves and a mechanism whereby the main truck frame is permitted to have a lateral motion to accommodate the side movement of the car.

Electric Railway Conductor, E. Thomson, 446,483. Filed March 22, 1890.

Consists of an improved method of supporting the trolley wire, in supplying the same with current, and in protecting it from short circuits or grounds caused by the falling upon it of other wires.

Controlling Switch for Electric Railways, F. B. Rae, 446,613. Filed Aug. 22, 1890.

For storage-battery cars.

Locomotive for Electric Railways, T. A. Edison, 446,667. Filed Aug. 7, 1882.

Claim 1 follows:

The combination of a car or truck and electric motor mounted thereon, a countershaft having pulleys, a tight belt from the armature shaft to said countershaft, and a loose belt from said countershaft to car, and a belt tightener for the latter belt.

Electrically Propelled Car, R. M. Hunter, 44'.817. Filed March 14, 1889.

Claim 1 follows:

A car having longitudinally arranged seats, end dashers, openings in one of the car body ends and in the dasher adjacent thereto in line with the spaces below said seats, and doors or covers for said openings in the car end and dasher for effecting the transfer of the storage batteries to and from the car.

Electric Locomotive, E. M. Boynton, 446,821. Filed Oct. 17, 1890.

Relates to means for connecting the armature shaft of an electric motor directly with the driving wheel of a bicycle or other vehicle without intermediate gearing.

Electric Railway, R. M. Hunter, 446,833. Filed March 16, 1888.

Has for its object to provide a suitable construction adapted to overhead conductors whereby strength, durability, simplicity, and low resistance result with cheapness of construction.

Electric Railway, R. M. Hunter, 446,834. Filed June 4, 1889.

A system of distribution for electric railways, in which there are employed extensive line or working conductors, the generator or generators being connected with different parts of the same circuit by suitable feeding wires.

Electric Railway Conduit, E. M. Bentley, 416,419. Filed April 9, 1890.

Relates to an electric railway in which the supply conductor is enclosed in a separate conduit beneath the surface of the road, and consists of certain means for supporting and insulating a conductor within a conduit of special construction.

Telegraphs :—

Telegraphy, R. G. Brown, 446,424. Filed Mar. 6, 1886.

Relates to "synchronous telegraphy" or "synchronous multiplex" telegraphy, and especially the Delany system.

Telegraphy, R. G. Brown, 446,425. Filed Mar. 6, 1886.

Claim 1 follows: The described method of transmitting messages in either direction at will over a single main line connecting two or more multiplex synchronous telegraph apparatus, consisting in causing thet ransmittin gimpulses to be set up over the wire where the receiver is disconnected therefrom. and receiving such impulses through the receiver while the transmitting generator is disconnected therefrom.

Telephones and Apparatus :—

Telephone-Call, D. H. Rice, 446,614. Filed Oct. 15, 1881.

Claim 1 follows:

In combination with a number of electrical circuits provided with individual call bells thereon adapted to be operated by synchronous pulsations of electricity, lines adapted to connect each circuit with a different number of cells of electric batteries, and a vibrating calling mechanism adapted to transmit synchronous pulsations of electricity to ring one or more of said bells.

Electric Switch, G. R. Lean, 446,623. Filed May 12, 1890.

A "quick acting" or "jump" switch and especially designed for multiple arc lighting.

Electric-Conductor Connection, H. Arld, 446,655. Filed Sept. 15, 1890.

Relates to improvements in terminals or binding posts for electrical circuits.

Magnetic Pulp-Separator, W. C. Edwards, 446,704. Filed Sept. 29, 1890.

Relates to separators for separating metallic particles from paper pulp by means of ordinary permanent magnets.

Patent Notes.

AN OFFICE DECISION IN FAVOR OF GAULARD AND GIBBS.

The patent of Gaulard and Gibbs of October 26, 1886, for a system of electrical distribution by alternate currents and converters, which is regarded as one of the fundamental patents of the Westinghouse Company, has been the subject of protracted interference proceedings in the Patent Office for several years past, prior invention having been claimed on behalf of two interfering applications, filed respectively by Rudolph M. Hunter, of Philadelphia, and Deprez and Carpentier, of Paris. Commissioner Mitchell has now rendered a decision affirming the priority of Gaulard and Gibbs as against both of the contestants.

THE SLATTERY-STANLEY INTERFERENCE.—DECISION FOR STANLEY.—PARALLEL DISTRIBUTION BY ALTERNATING CURRENTS.

It will be remembered that in 1887, the Westinghouse Electric Co. brought an action under the Gaulard and Gibbs patent of 1886, against the Sun Electric Co., of Woburn, Mass., alleging infringment of the claims for a potential reducing converter system of distribution by alternating currents. The suit was finally defended by the Fort Wayne Jenney Company, who had meantime secured control of the Sun Co., and was decided in favor of the defendant, mainly on the ground of non-infringement, the patent showing the converters in series, while in the alleged infringement the converters were placed in parallel. Slattery, in behalf of the Fort Wayne Co., then made application for a patent on April 5, 1888, which was granted on July 31, following, the claims of which covered, in substance, any parallel system in which the counter-electromotive force in the converters is practically made equal to the direct electromotive force when the secondary circuits are open, which is, of course, an essential condition in all systems of multiple arc distribution by alternating currents. Immediately after the issue of this patent, an application, claiming the same thing, was filed by William Stanley, Jr., on behalf of the Westinghouse Co., who proved that he had experimentally operated a plant involving the invention, at Great Barrington, Mass., early in the spring of 1886. Interference proceedings were instituted which have been prosecuted with great vigor on behalf of both contestants. The Examiner of interferences and the Board of Examiners-in-Chief both decided in favor of Stanley, and we now learn that Commissioner Mitchell, on appeal, has affirmed the decision of the lower tribunals, which terminates the controversy in favor of Stanley and permits his patent to issue.

Legal Notes.

A $200,000 SUIT AGAINST THE WENSTROM CONSOLIDATED CO.

Chadbourne, Hazelton & Co., of Philadelphia, the general agents for the United States, for the Wenstrom Consolidated Dynamo and Motor Co., of Baltimore, have brought suit againt that company in the sum of $200,000 for commissions due and breach of contract. The claim is based on the alleged inability of the firm to fill electric railway contracts because they could not get the apparatus from the manufacturing company. As we go to press we have received from Chadbourne, Hazelton & Co. the following open letter, in which they present their case. The item from the Philadelphia *Times* enclosed gives the information of the above nature, and need not be quoted:

> In connection with the enclosed article from the Philadelphia *Times* of February 27, we want to say a few words in explanation.
>
> About a year ago, the Wenstrom Consolidated Dynamo and Motor Co. was organized in Baltimore, being the outcome of a consolidation known as the Wenstrom Northern and Wenstrom Southern Electric Companies.
>
> The officers and Board of Directors of the Wenstrom Company were such well known men, that it seemed unnecessary to question very closely into the details of the organization. Mr. Tunis, the president of the company, came to us, and negotiations were commenced, whereby we should take the general agency of the company. He impressed upon us most forcibly, the financial, political, and social standing of his Board of Directors, and assured us that the company would have unlimited backing from them and that there was sufficient money forthcoming to put the company in the foremost ranks of the electric companies, and it lay with us to make it a success.
>
> We gave the matter careful consideration, and thoroughly believed that we were to represent an electric company that would be the rival of any company in the country. It takes a good deal of money to run a successful electric company, and it takes a good deal of push, and hard work and energy. We were prepared to supply the latter, and expected the Wenstrom Company to provide the capital to manufacture their apparatus.
>
> As is generally known, we accepted the general agency for the United States and organized a selling department with about 15 sub-agencies throughout the United States in the principal cities, and we started in to work under what we believed to be the most promising circumstances. Nearly a year has passed, and on looking over our records, we find that only about 5 per cent. of our orders accepted by the Wenstrom Company for dynamos and motors have been filled.
>
> Only a few days ago we announced the closing of an important railway contract in Denver, Colorado, some 14 miles of track and various heavy electric locomotives and car equipments, and also a contract in Athens, Ga., and orders for equipments on several other roads. All these contracts and orders were accepted by the Wenstrom Company, but within the last few days it has become apparent that some of the most important at least they will be unable to fill, so that the railway contracts which include the overhead construction, amounting to about $225,000, will probably be equipped with some other system.
>
> We have been promised time and time and again that the company would be on its feet and that the work would be pushed and that goods would be delivered. But the time has come when we can no longer wait, and we feel that we have already injured ourselves in the eyes of our customers and the electric world by the repeated promises which we have made and been unable to fulfill. Outside of the large pecuniary loss to ourselves, we feel most deeply the humiliating position in which we have been placed. We have received kind and encouraging words from our many friends in the business, and from the various journals who have offered their columns to us, and we wish them to understand that we have been misled.
>
> Mr. Hazelton and myself, feel that the time has come when we must take a stand. While we can't undo the harm that has been done, yet we are more desirous of placing ourselves straight before the people with whom we have been dealing than anything else. It is unnecessary to say that we shall stick to the "electric" business, and while we have not the most remote idea, as to what our future steps will be, yet we are sure of one thing, that if we ever undertake to represent any company or attempt to close any contracts for the delivery of any kind of apparatus, electrical, or otherwise, we will assure ourselves that we can deliver it witnin a reasonable time.

Obituary.

T. P. CONANT.

The death last week, on Feb. 24, of Thomas P. Conant, was a cause of great surprise and grief to electrical engineers in this city and elsewhere. He had been ill some time and succumbed at last to rheumatism of the heart. Mr. Conant was born in Paris in June, 1860. He was educated at the Columbia School of Mines, from which he was graduated in 1882. He then became Mr. Thomas A. Edison's secretary, and made rapid progress in electrical engineering. He was for a while actively connected with the Electrical Accumulator Co., of this city, both here and in Chicago. At the time of his death he was engineer for the Eastern district, comprising this state and a part of New England, for the Edison General Electric Co. Mr. Conant was a member of the Manhattan Athletic Club, the Electric Club, the American Institute of Electrical Engineers, and numerous other electrical and engineering societies. His funeral was held Friday at the home of his grandfather, the Rev. Dr. T. J. Conant, Washington street, Brooklyn. The Rev. Dr. Lyman Abbott conducted the services.

DR. N. AUG. OTTO.

We regret to record the death of Dr. N. Aug. Otto, the inventor of the celebrated Otto gas engine, who succumbed to a brief illness, at Cologne, Germany, on January 26, and whose career exemplifies the success of perseverance and energy, coupled with ingenuity and skill. Dr. Otto was an honorable man, esteemed by all who knew him, and, though not trained as an engineer, he made himself one by hard work and study. His achievements abundantly prove his great theoretical knowledge, mechanical dexterity, and fertility of resources.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Brisk advertising of your goods is a sign of life, constant activity, springtime and a rising tide of prosperity."

THE ONGLEY ELECTRIC REGISTER AND SAFETY SIGNAL.

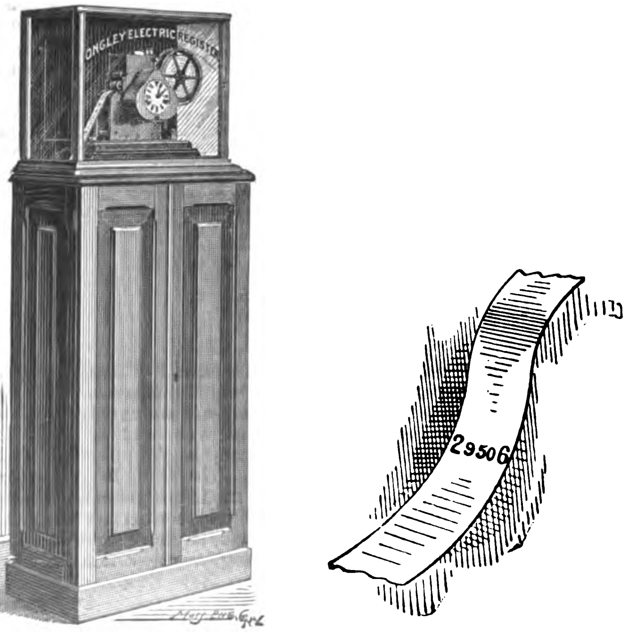
An automatic safety signal system, which will record in print any neglect of the night watchman, give a prompt alarm in case of fire, and enable the engine to be immediately stopped from any distant point, independently of the engineer, will command the attention of all owners of factories, hotels, and other large buildings in which the faithful services of a watchman are essential.

All these valuable qualities are possessed by the Ongley Electric Register shown in the accompanying illustrations.

The register, shown in Fig. 1, prints upon a strip of paper the time at which a watchman reaches any station in his rounds, together with the number of that station; for instance, the slip shown in Fig. 2 puts upon record the fact that the watchman reached station No. 26 at 9:50. If the clock should stop, or be damaged, the number of the station would still be printed, and the time omitted.

The station apparatus shown in Fig. 3 consists of an iron box, resembling a messenger call, the handle resting normally at 0; and at the top of the board, in Fig. 4, is seen the automatic recorder.

The operation of the device is as follows: If it is desired to signal the engineer to start the engine, the handle of any station apparatus is turned to "1." This means "start slow." In the two lower squares of the recorder in the engine room, immediately appear the figures composing the number of the station from which the signal was given, while the number "1" occupies the upper square. At the same time a bell rings continuously until turned off by means of the handles, which also remove the figures from the recorder, leaving the three squares empty. The register in the office, has in the meantime printed *once*, the number of the station, and the time. The handle is then placed on "2," which means "full speed," whereupon the station number appears in the two lower squares of the recorder as before, the figure "2" appearing in the upper square; the bell again rings until shut off, and the register prints the station and time *twice*. In case of fire, the handle is placed on "3," and a button at the bottom of the box is pressed. This gives the alarm in the engine room, prints the record on the register three times, and at the same time starts a special steam pump.

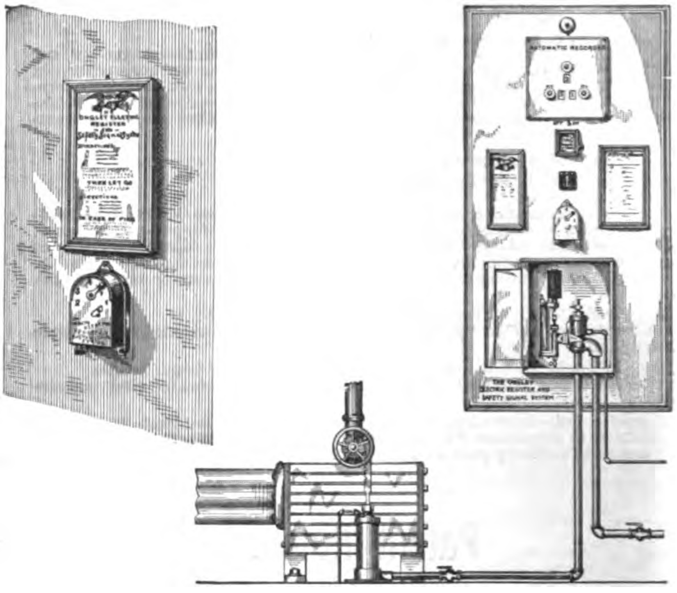


Figs. 1 and 2.—The Ongley Electric Register and Safety Signal.

To stop the engine the handle is brought upon "4." This operates, by means of an electro magnet, a small hydraulic valve, shown in Fig. 4, which, in its turn, opens a larger valve, admitting water into a vertical cylinder placed beside the steam chest. The piston rod of this cylinder terminates in a rack, which engages a gear wheel at the throttle valve, and shuts off the steam. Simultaneously the register prints the record four times, and the bell in the engine room rings until turned off, while the figures on the recorder show the station and signal number, as usual.

When the engine is not in use, the register merely keeps a record of the movements of the watchman, and also, if desired, of all doors or windows that are opened.

One of these instruments has been in use at the factory of F. J. Kaldenburg, in this city, for more than a year, during which time it has given the most satisfactory results, and has required no repairs. Here the current is supplied by twelve cells of Samson battery.



Figs. 3 and 4.—The Ongley Electric Register and Safety Signal.

The Ongley register has been approved by the New York Board of Fire Underwriters, the Philadelphia Fire Underwriters' Association, and the South Western Tariff Association, of Atlanta, Ga.

The register is manufactured by the Ongley Electric Company, of No. 1 Broadway, and is already in successful operation in a number of factories, etc., throughout the country.

CLEVERLY'S TRAITS AND TRAYS.

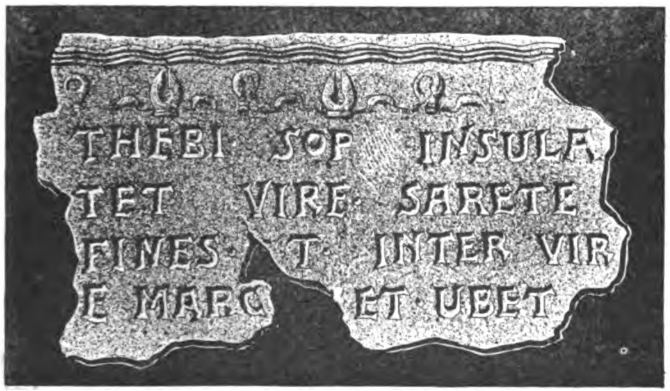
For a long time past the handsome gifts presented to his male friends by Mr. H. A. Cleverly, of Chestnut street, Philadelphia, have been greatly admired. The quiet, good taste, sound æsthetic judgment and profuse generosity of this second Franklin have been exhibited in blotting pads, calendars, thermometers and other bargain counter bric-a-brac, and the result is that to-day the name Cleverly is venerated in every office and household where it is felt that life without a chromo of some kind from him every three months would not be worth living. But Cleverly never disappoints his friends; on the contrary, he always rises superior to their expectations—except when they strike him for an "ad"—and now he once more comes forward bearing gifts. This time it is something to please the ladies of the electrical profession, and takes the shape of a magnificent cut-glass, superfine tray for preserves. The glass is of extraordinary hardness. Last week Mr. Cleverly threw a tray jocularly at the head of a persistent advertising canvasser from Chicago. It hit him on the cheek but did not break. The color of the glass is also exquisite in its purity and innocent whiteness, while the sparkle of each facet is a further delicate reminder of the donor's ceaseless play of fancy. Before retiring with the large fortune which he cheerfully and gladly admits is wholly due to his free and unstinted use of printer's ink, Mr. Cleverly wishes to make every electrical home happy with one of these trays; and he will therefore send one on application to any address on receipt of $2.25 and a stamped envelope as a guarantee of good faith. As the trays retail for $1.75 at Wanamaker's, it will be seen that Mr. Cleverly is simply trying to accumulate a fund towards meeting the expenses of his next appearance in the role of Santa Claus. Due notice will be given of that performance. Mr. Cleverly asks us to say that if the $2.25 is not remitted, he will still send the tray, and will open an account for it in case the recipient is not already in his good books.

THE UNIVERSAL ARC LAMP CO.

A significant proof of the new ideas prevalent in electric lighting was shown in the great interest taken at Providence by arc and incandescent men in the display made by the Universal Arc Lamp Co., who were represented by Mr. E. S. Mendels, the general manager. Two of the Universal lamps were displayed right in the centre of the exhibition hall on mast arms. Any weakness or failure would have had prompt and mortifying exposure, but they burned on all the time, brilliantly, steadily and noiselessly, running on a direct current of 110 volts, and consuming 8 amperes. This notable exhibit was the theme of much warm commendation as proving the desirability and availability of this mode of arc lighting for interior as well as exterior illumination, doing away with high tension wires where they would be most apt to do harm. Mr. Mendels would have talked himself hoarse answering inquiries, but for the generous provision of liquid hospitality by the good folk of Providence. and since his return home he has been unable to keep pace with the demand for information, prices, etc., from those who saw the lamps.

BISHOP WIRE AMONG THE ANCIENT ROMANS.

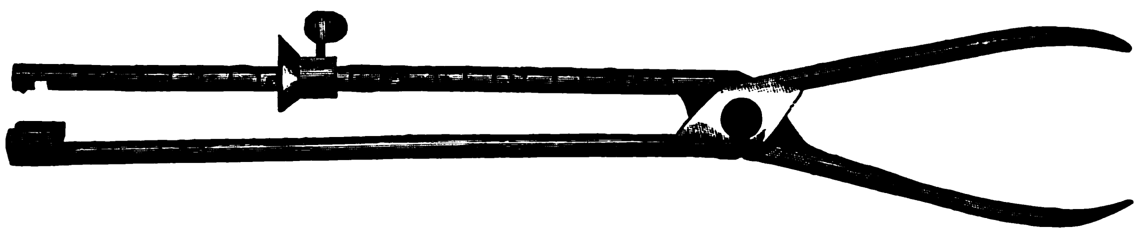
One of the most strikingly novel circulars it has been our privilege to see, was that distributed at the Providence Convention, by the Illinois Electric Material Co., of Chicago. Not content with anything of modern character, they have returned to the dark and misty ages for a fitting tribute to the merits of their insulation, which the ancients seem to have held in high esteem. This weird cryptogram, being translated, is as follows: "The Bishop insulated wires are the finest in the wire market, you bet." We are also assured that the antique touch never affects the insulation of their wire. It is further stated that this is the real philosopher's stone, and it is only necessary that purchasers of high grade wire should follow its instructions in order to learn the heretofore hidden secret of making gold.



Bishop Wire "Ad." Found at Pompeii.

A GLASS TUBE CUTTER.

The accompanying illustration represents a glass tube cutter manufactured by Hunt & Connell, Ltd., of Scranton, Pa., and designed for cutting gauge glasses to length. One arm has a scale in inches and fractions of an inch, a slide stop with set screw, and a rotary cutter at the end. This arm is inserted in the end of the glass tube to the required distance, against the slide stop or gauge, the outside of the glass tube resting in the circled end of the other arm. With a slight pressure of one hand on the handles, and a rotation of the glass with the other hand, the rotary cutter makes an even cut around the inside of the tube, and a very little pressure breaks it off. The device is made in two sizes, cutting up to five and seven inches, respectively.



A Novel Glass Tube Cutter.

PARTRICK & CARTER CO.

Mr. Thomas L. Townsend will start early in March on his Spring trip in the interests of the Partrick & Carter Co. He will cover a very large territory this time, and will have, in addition to the standard goods of this house, several novelties which they are making, especially for the house goods trade. The new "King" annunciator will certainly be a go.

ADDITIONAL STORAGE BATTERY CARS ORDERED BY THE DUBUQUE COMPANY.

The Dubuque Street Railway Company is so well pleased with the experimental storage battery car operated on the Edco system and which has been running in regular daily service since last August, that it has concluded to order from The Accumulator Company three additional cars of the same kind, work on which, we are advised, has already been started; delivery to be made in April. This will make nine Edco cars in all which the Dubuque Company will have in operation, the first six of which are about ready for delivery, and will be installed in March.

We are informed also that The Accumulator Company has arranged with the Eckington & Soldiers' Home Railway Company to rent them two Edco cars, which are about ready for delivery, and which are to be operated by the Eckington & Soldiers' Home Railway Company upon the G street branch of that road between the Treasury Department and the Pension Office, thence to the corner of New York avenue and 5th street, pending the delivery of the six new Edco cars recently contracted for which will not be ready for delivery till about May or June.

THE ENGINEERING EQUIPMENT CO.

The Engineering Equipment Co., organized early in February have located temporarily at 73 Cortlandt street, New York. After April 1st they will be in the new Jersey Central building, Liberty, West and Washington streets.

The following gentlemen and others are actively interested in this new and promising enterprise: F. A. Magee, M. E., engineer; F. L. Perine, general manager; A. L. Tinker, secretary and treasurer. The company are contractors for steam and electric equipment materials. They represent the Underwood Manufacturing Co., of Tolland, Conn., makers of cotton-leather belts, and other specialties in the belting line, and are sole agents for the patent indurated fibre pipe used in electrical subway work and for other purposes. The Engineering Equipment Co. are also manufacturers' representatives of Corliss and high speed engines, horizontal and vertical boilers, wooden and iron poles, line materials, wire and cables, underground conduits, cars and trucks, iron roofs, cranes, etc.

It is the purpose of this company to furnish equipment materials of the best class at figures which will be attractive to intending purchasers, especially to those who desire to place large orders in safe, reliable hands and under conditions that will insure the exercise of sound judgment by experienced engineers.

A VERDICT FOR THE GOULD & WATSON INSULATORS.

The Detroit *Tribune* of Feb. 21, makes the following note: "The Gould & Watson Co., an Eastern concern founded for the dissemination of electrical appliances, sold a large number of insulators to the Detroit Electrical Works some time ago for use on street railways which are being built by the local concern in various parts of the country, including Texas. It was claimed after trial that the insulators were not all that they were represented to be, the composition of which they were formed yielding to the influence of the sun, and various other things which have no legitimate connection with rapid transit, and the Detroit company declined to remit until matters were straightened out. A replevin suit followed, resulting in a verdict yesterday afternoon for the foreign concern for $501.12."

Mr. H. E. Chubbuck, of Springfield, Ohio, has been in Chicago, exploiting the malleable brackets and break-arms which bear his name.

THE THOS. MURRAY CO.

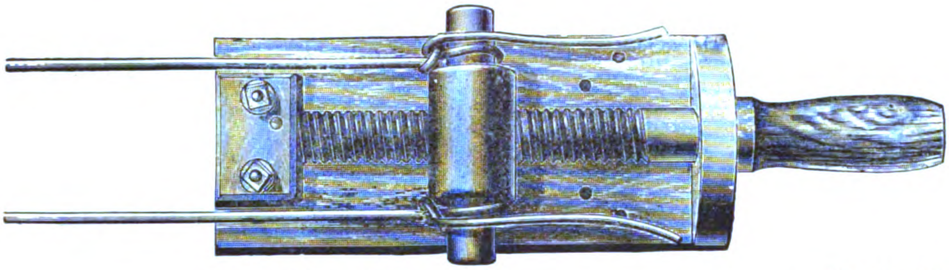
The Thomas Murray Company, of 95 Liberty street, New York, have received additional contracts for overhead construction for the Consolidated Street Railroad, of Columbus, O They expect to have the construction completed and cars running by June first. They have also commenced the work of the Grand View Beach Railroad, at Charlotte, N. Y. They expect to have this road completed and in running operation about May 15. This road is to be equipped with 40 h. p. Rae motors, Brill and Newburyport cars. It is expected to be one of the finest roads in the country.

BROWNLEE & CO.

Brownlee & Co., of Detroit, Mich., report the largest sales of poles for January and February that they have ever had. Their new steel poles are being very favorably received, and trade in wooden poles is growing rapidly. They have recently purchased 25 acres of ground at Detroit and will establish a large pole yard there. This will bring them about 200 miles nearer their customers and enable them to make very prompt deliveries.

A PATENT WIRE STRETCHER.

Wiremen and all parties engaged in running wires for electrical purposes cannot fail to appreciate this innovation in the line of construction tools, recently placed upon the market by L. E. Wilcox & Co., of Meriden, Conn. It is claimed that by its use one wireman can do the work ordinarily requiring two. The work is done with great neatness and facility and is not an eyesore.



Novel Wire Stretcher.

To use the stretcher it is only necessary to fasten it to the ceiling at one end of the line by means of screws, then, after fastening the wires at the other end of the span by means of cleats or porcelains, to pass the ends of the wires around the ends of the wooden nut and stretch the wires by turning the screw until the wire is perfectly taut and all kinks have disappeared. The cleats and rosettes are now placed, the stretcher taken down, and the next span proceeded with in like manner.

ACTIVITY OF THE DETROIT ELECTRICAL WORKS.

The Detroit Electrical Works, Detroit, Mich., through Mr. C. A. Benton, the indefatigable manager of their street railway department, have just closed a contract with the Eau Claire Street Railway, Light and Power Co., of Eau Claire, Wis., for two 30 h. p. equipments of the famous Rae system.

Mr. Joseph E. Lockwood, for many years with the Brush Electric Co., of Detroit, and well known as a bright and able electrician, has recently associated himself with the Detroit Electrical Works, who are to be heartily congratulated on adding another shining light in the electrical field to their staff. Mr. Lockwood will supervise the construction work.

GREAT SUCCESS OF THE INTERIOR CONDUIT SYSTEM.

The "interior conduit" system is meeting with phenomenal success upon the Pacific Coast. The Interior Conduit and Insulation Company are just in receipt of an order from their San Francisco representatives, Messrs. Thos. Day & Co., for 150,000 feet of tube, besides elbows, sleeves and all the other appliances which go to make the system complete in its every detail.

The system is to be used throughout the new Mills Building, of that city. The Mills Building, of San Francisco, designed by Messrs. Burnham & Root, architects, of Chicago, will be several stories higher than the Mills Building, of New York, and will be lighted throughout by electricity, there being about 7,000 incandescent lights.

The Interior Conduit Co. has now received its Gold Medal, awarded it lately by the Massachusetts Charitable Mechanics' Association, for the fine exhibit made in Boston of its devices and appliances, and for the merit of the system.

THE BRAZELLE AUTOMATIC HYDRAULIC ENGINE GOVERNOR.

The accompanying illustrations, Figs. 1 and 2, show the Brazelle automatic engine governor, designed to maintain uniform speed of engine with all changes in loads.

The governing is effected by a force pump, A, Fig. 2, pumping oil against a piston B, through an opening C; this opening may be increased or diminished, to change the speed of the engine, by turning the hand-wheel D. The piston rises and falls by the action of the pump, thus regulating the supply of steam to the cylinder. It is claimed that the governor will admit fully 90 per cent. of the boiler pressure to the cylinder when necessary, and that, by turning the hand wheel D, the speed of the engine can be regulated from 20 to 300 revolutions and over. For incandescent lighting it commends itself, as its perfect control of the engine insures extreme steadiness of the light, and thus adds to the life of the lamps.

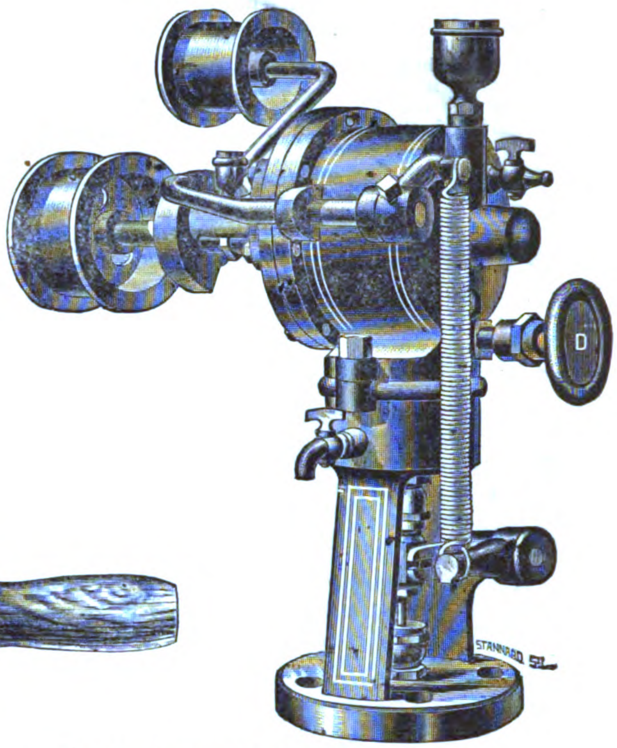


Fig. 1.—Brazelle Automatic Governor.

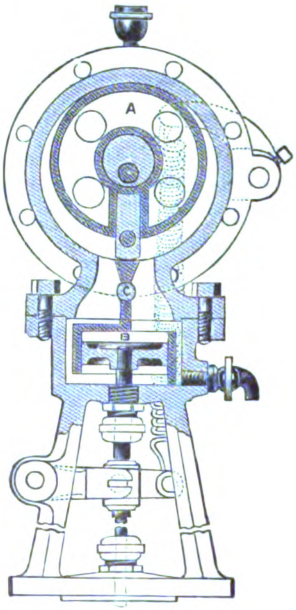

Fig. 2.—Detail of Brazelle Governor.

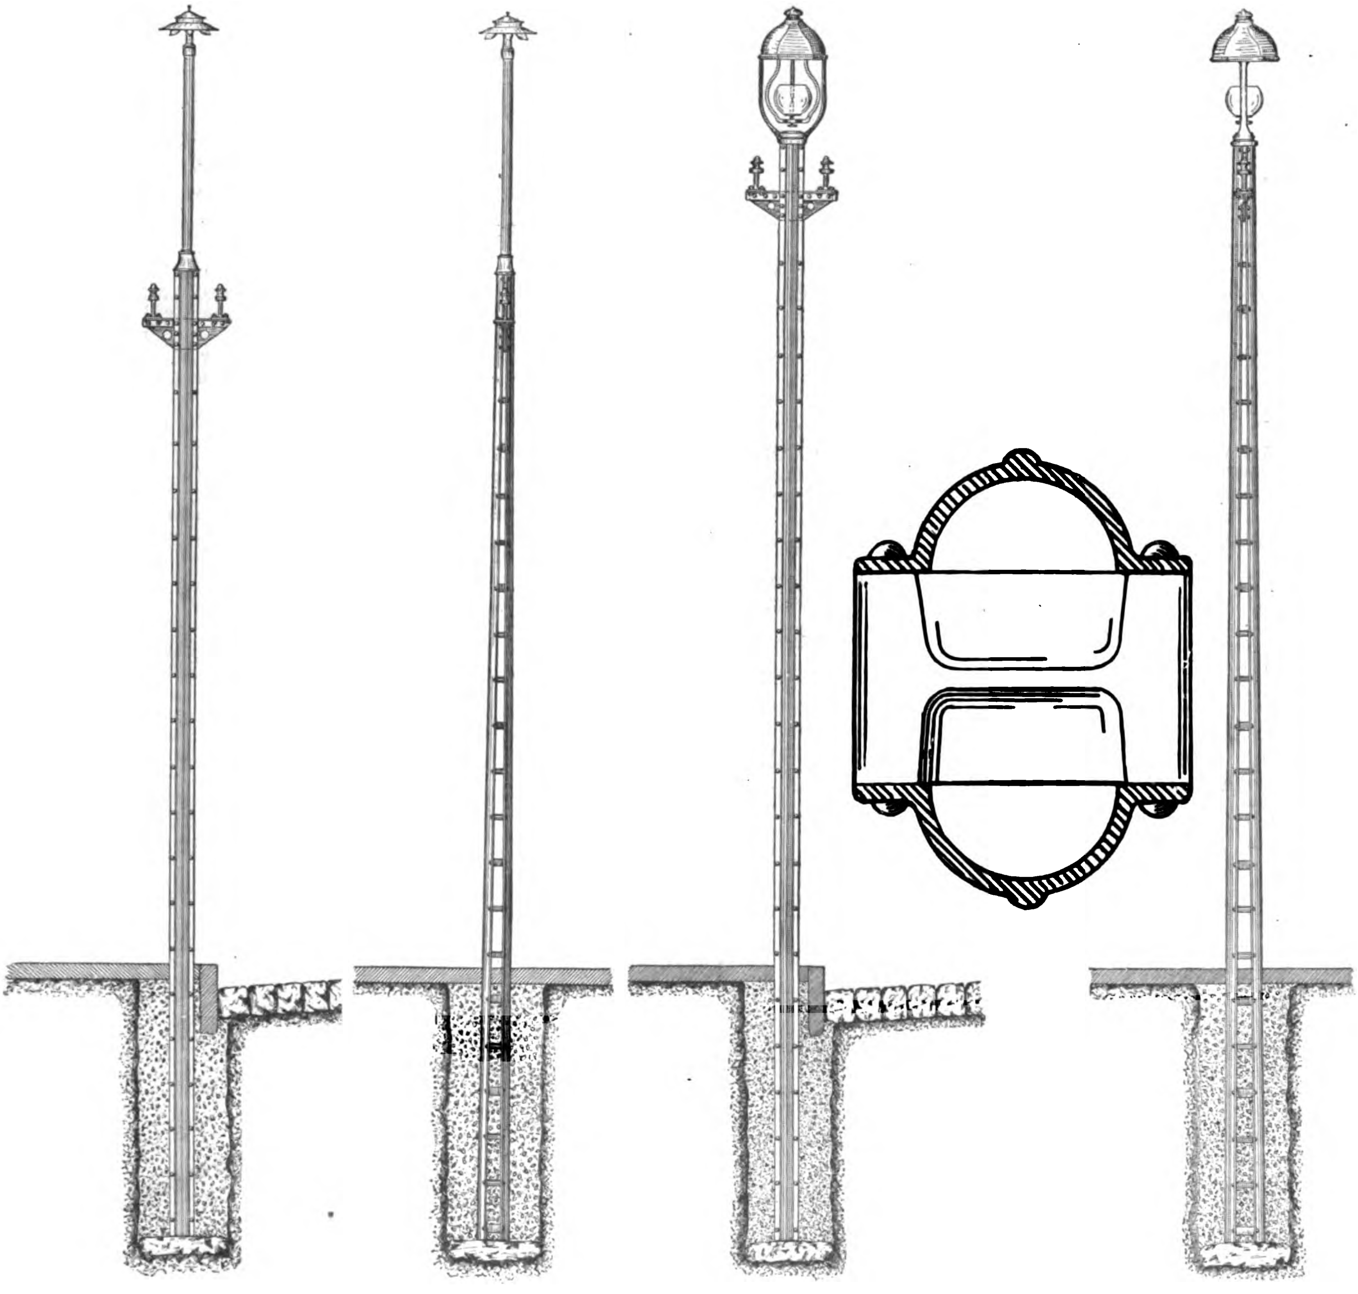
The Brazelle governor is manufactured by the Mid-Continent Manufacturing Co., of St. Louis.

MILLIKEN'S NEW ELECTRIC LIGHT POLES.

THE accompanying illustrations, Figs. 1 to 5, show a new form of pole for electric light work. This pole is manufactured by Milliken Bros., of 55 Liberty street, New York, and is an outgrowth of their street railway pole, recently illustrated in our columns, and which has met with such success.

These poles are constructed of two longitudinally flanged segments, connected by rivets and gas pipe separators, which vary in length, and thus give the pole a taper from the ground to the top. Occasionally cast iron separators are introduced to keep the segments in line. The section of the pole, Fig. 5, shows the form of the cast separator. They are claimed to be much lighter, and consequently cheaper, than any other form of pole made, as the minimum amount of material is used, representing the greatest strength. The greatest diameter of the pole is at the base, where the strain is the greatest.



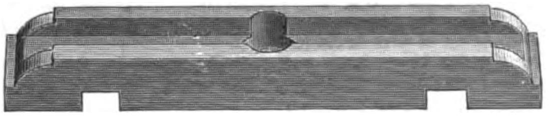
FIGS. 1, 2, 3, 4 AND 5.—MILLIKEN'S ELECTRIC LIGHT POLES.

The Standard incandescent light pole, Figs. 1 and 2, is arranged for the lights to be 18 feet above the street. The pole is set in the ground 5 feet. The brackets shown are arranged for two wires, although more can be used if necessary. The top of the pole is supplied with a cast iron reducer into which 1½ inch gas pipe screws. The top of the gas pipe is threaded to receive a hood which carries the lights. The hood is furnished by nearly all the electrical companies, and can be arranged with a reflector when necessary. When these poles are used in connection with subways, a hole is cored in the cast iron separators, and the wires then pass directly up through the centre of the pole. They can be protected by any of the usual forms of insulation and cut-outs, or switches can be inserted at convenient points. The arc light pole, Figs. 3 and 4, is similar in construction to the incandescent light pole, just described, except that the pole proper runs to the base of the light. They can be arranged at the top to fit any special make of lamp, and can also be arranged for carrying the incandescent or arc lights on arms of any length.

These poles have been extensively used in South American countries for ordinary forms of line work, such as telephone and electric light work. It has been found that, in these warmer countries, different kinds of insects attack wood, and in a very short time entirely destroy the fibres, causing the pole to break short off at the surface of the ground. Companies have also found great trouble in keeping lines in operation where they pass through thinly settled districts, as the natives cut down wooden poles and use them for fire wood. When furnished for line work, they are supplied with an iron cross-arm on which any number of pins are secured. These poles can be made of any length, and varying thickness, according to the strain put upon them. It is believed that such poles will find an extended use, especially after the experiences of the recent severe and troublesome winter.

A NEW "CROSSING" CLEAT.

The crossing cleat shown here has been brought out by the Electrical Supply Co., of Chicago, to answer the call for a device which shall not be cumbersome and yet permit the crossing of wires safely and conveniently. This cleat seems to fill the whole bill, and is unique in this respect at least, that it is no larger than the regular working cleat. It is necessarily more carefully made than the ordinary cleat, and will doubtless find favor with those requiring neat construction.



A "CROSSING CLEAT."

PERFECT SATISFACTION.

The Jerome Kidder M'fg. Co., of 820 Broadway, have received the following letter:—

401 N. High St., CHILLICOTHE, O., Feb. 3rd, 1891.

DR. JEROME KIDDER, 820 Broadway, N. Y.

Dear Sir:—Yours of the 30th received. Also Battery No. 5, packed with care and in good order. I find it all that you represent it to be. It gives perfect satisfaction. Enclosed find draft.

Very respectfully,

REV. F. SCHWAB.

THE BARRIETT ELEC. CO.

The Barriett Co. has changed its address from 120 Broadway to 10 Cedar street, where it has established its office and works. Mr. Barriett is busily engaged getting things into shape there, and is already turning out motors and other electrical work.

THE "AJAX" DRY BATTERY.

The Electrical Supply Co., of Chicago, reports a recent test of its "Ajax" dry battery with five of its competitors, in the following:

On Nov. 4th, 1890, the six batteries were selected from new stock and the voltage of each was taken. Four of them showed a greater E. M. F., and one was lower, while the Ajax stood at 1.32. They were then put on a circuit of 20 ohms resistance, and continued so until January 7th, 1891, at which time the Ajax stood .12 above the lowest and .02 above the next highest. On the last named date they were all disconnected and allowed to rest until February 13th, at which time the Ajax showed its great recuperative powers by standing at 1.18, only .14 below where it started one hundred days before, and after doing sixty-four days' continuous work. The next highest stood at .02 below the Ajax and the lowest at .20 below. After all this work the Ajax rang a bell as vigorously as ever, and it is claimed for it that it may stand on the shelf unused for months and lose none of its E. M. F.

PERKINS ELECTRIC LAMP CO.

The Philadelphia office of this company will be located at No. 806 Walnut street. The Boston agents are the well-known firm of Claflin & Kimball, 116 Bedford street, Boston.

THE WENSTROM CONSOLIDATED DYNAMO AND MOTOR COMPANY.

When this company came before the public last spring, it was their expectation to supply goods manufactured in their old works, and they expected to have their new factory completed by September 1, 1890. So rapidly, however, was the selling department of the business organized, that the facilities which the company had were soon over-taxed, and the result was that they were unable to fill their orders promptly. Every effort was then turned towards the rapid completion of the new factory at Calverton Heights, Baltimore, Md.

Many annoying delays arose, but Mr. Tunis, the president of the company, pushed ahead in spite of the numerous obstructions, and his efforts are at last crowned with success in the completion of the present factory.

The building is 100 feet front by 260 feet deep, two stories high in front, and four in the rear. No effort has been spared to make it the most substantial and complete electrical factory in the country. The building is situated at Calverton Heights, where there is one of the finest water powers in the State. The company purchased this entire property, consisting of nearly 100 acres, with the view of erecting a series of factories similar to the first, as the business demanded, and also to afford ample room for houses for their workmen and the laying out of the small town which must necessarily rise about such an important manufacturing centre.

Mr. H. F. Parshall, who is well known as an expert electrician, and more widely, perhaps, as the designer of some of the most successful electrical apparatus in the country, has had complete charge of the electric work connected with the Wenstrom Company. He has fitted up the factory with a large amount of high class tools, which will enable them to turn out fine apparatus with great rapidity.

A large number of Wenstrom dynamos had been manufactured and put in operation in this country by the Wenstrom Company before its re-organization, and it is interesting to note that all of these have been entirely satisfactory, although manufactured under the original designs without any of the most modern improvements in mechanical details which are commonly used in the most perfected machinery.

Since Mr. H. F. Parshall has been head of the Electrical Department of the Wenstrom Company, he has made many important changes in designs and general details, and has brought the Wenstrom apparatus up to the highest standard.

NEW ENGLAND TRADE NOTES.

THE JEWELL BELTING COMPANY, recognizing that the demand for electrical construction throughout the country during the coming year will be enormous, have now arranged their works so as to meet all the requirements of a rapidly increasing business in dynamo belts. They have never had so many large driving belts in process of construction at one time as now. Most of them are to transmit power in electric light and power stations. The collection comprises two belts 40 inches wide, one 36 in., one 35 in., four 32 in., one 30 in. three-ply thick, two 30 in., two 24 in., one 23 in., besides a large number ranging from 16 inches to 20 inches.

THE EASTERN SUPPLY AND CONSTRUCTION COMPANY, of Boston, have appointed Mr. H. F. Kellogg as manager of their light and power department. Mr. Kellogg has been associated with this company as salesman, and his early training with the Thomson-Houston Company adapts him well for this class of work. The business of the company is rapidly increasing in all its branches, and they are at present engaged in a number of electric railway enterprises.

THE ECONOMIC ELECTRIC MANUFACTURING COMPANY, of Boston, have appointed Mr. E. A. Clark as general agent for the sale of their lamp. Mr. Clark has been for some time connected with the Economic Company, having had charge of their mechanical department at Brockton, so that he brings with him a thorough practical knowledge of the manufacture of incandescent lamps. The Economic Company are now making about 700 lamps a day, and are adding to their facilities of manufacture all the time. Report has it that the Economic lamp is a good one, and is well worthy of a trial by all consumers of incandescent lamps.

THE ELECTRIC AND MACHINE COMPANY, of Boston, owing to the increase in their business and for the convenience of their customers, have transferred their offices from the fourth floor to the first floor, and have now a comfortable suite of offices, within reasonable distance of the sidewalk. Mr. J. C. Wilson, the proprietor of the company, is also now better able to give more of his time to consultation work, and his long experience in electrical business of every variety should make his advice valuable to all enquirers.

THE ELECTRIC GAS LIGHTING COMPANY have just issued another circular full of "most positive and convincing evidence" of the superiority of the Samson battery. It consists of extracts from letters of innumerable users, and a most interesting comparative report by Prof. Dolbear on the performance of two cells Leclanche and two cells Samson. If any one still doubts the Samson, let him at once procure this circular, read and be convinced.

WESTERN TRADE NOTES.

MR. FRANK R. MERRILL has completed arrangements to handle the storage batteries of the Consolidated Electric Storage Co., of New York, and the Loomis system of incandescent lighting, manufactured by the Eureka Electric Co., of New York. Mr. Merrill has opened handsome offices at 565 Rookery building, and will be pleased to see his many friends there

MR. W. R. MASON, the manager of the Electric Merchandise Co., of Chicago, has just returned from Pittsburgh, where he secured the agency for the Tramway Rail Co., manufacturers of steel rails, chairs, and auxiliary appliances for street railways. The Tramway Rail Co., by reason of their large means and unusual facilities, will immediately take rank with the foremost manufacturers of rails in the country. The Electric Merchandise Co. are increasing their business all the time, and in the acquisition to their staff of Mr. D. B. Dean, as general traveling representative, will extend their trade more and more.

THE
Electrical Engineer.

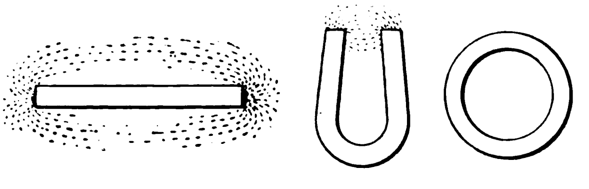
VOL. XI. MARCH 11, 1891. No. 149.

ON CHANGE OF FORM AFFECTING A MAGNETIC FIELD.[1]

BY

A. E. Dolbear

HITHERTO the study of a magnetic field has been the study of the so-called lines of force radiating from the poles of magnets, either electro or permanent, and so far as magnetism has been utilized in the arts, the changes in this external field have been brought about by the movements of an armature, having for its function to determine the direction and consequent density of the field. Such is the case in the instruments used in the telegraph, the telephone, dynamos and motors. Sometimes conducting wires are so mounted in the field that their movement gives rise to electric currents, which signifies that the energy producing the tension in the field is absorbed in some measure by the moving wires, and is transformed into an electric current. In each of these cases, the magnet producing the field is stationary, that is, changes in the magnetic field produced by it, are due to motions external to the magnet itself and may be that of an armature, of moving wire, or of its own bodily change of position—a kind which is comparable with what is called external motion, in thermo-dynamics, to distinguish from internal motions or such as take place when the body changes its form. So far as I am aware, no study has been made of the effects of changing the form of a magnetic body on its field, or of the reaction upon itself, of its magnetic condition due to a periodic change of form. Of course, it has been known for a long time that the form of the magnetic field depended upon the form of the magnet itself. For a straight bar magnet, this field is familiarly known by the arrangement of iron filings forming curved lines from each pole re-entering the opposite pole, as in Fig. 1. When the iron is bent into a U form or horse-shoe magnet, Fig. 2, the field is contracted to little more than the space between the poles. These forms of magnets have been *permanent* ones for the purpose for which the magnets were made.

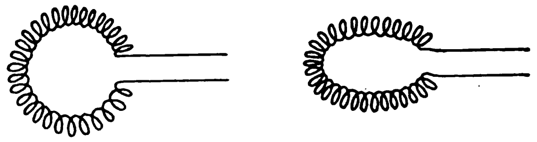


FIGS. 1, 2 AND 3.

In the case of an induction coil, whether of one form or another, the magnetic change produced by it, has been and is due to the *electric* change produced upon it by an electric circuit provided with intermittent or alternating currents.

Within a few years attention has been called to the nature of the external field, as being a part of what is now known as the magnetic circuit, which consist of these *rings* or closed circuits of lines of force, all originating in the iron part of the circuit, and for *conducting* which, iron is by far the best. The poles of the magnet are simply the parts of the iron where the lines enter and leave, and they may be in any place. Usually they are at the ends of the iron, but not necessarily so. Whenever iron is placed in the magnetic field, these lines crowd into it, as it is so much better conducting than the ether. When the iron is made into a ring, Fig. 3, and then magnetized, there is no external polarity and, consequently, no external field, provided that the iron has sufficient conducting cross section at every part.

The following experiments have been tried, to determine what effects, if any, are produced upon a magnetic field by changing the form of a magnet. It was thought, at first, that if a helix was coiled into a circle, Fig. 4, and a current was present in it, a change in its form to that shown in Fig. 5 would produce a corresponding change in the magnetic field external to the coil, especially noticeable if a flexible iron ring was enclosed in the helix so as to condense the magnetic field. This was put to the test in the following manner:—



FIGS. 4 AND 5.

(I.) A coil, similar to the one described above, but containing a solid ring of iron, about eight inches in diameter and an inch thick, had its coil put in circuit with a reflecting galvanometer of low resistance, and at such a distance from it that magnetic fields external to its circuit could not act upon it. Another coil, made about a flexible ring of iron wire, was put in circuit with a battery so as to magnetize the ring strongly. Then, with one ring parallel to the other, the flexible one was made suddenly to assume an elliptical form, Fig. 6. Each such change in form from one ellipse to another at right angles to it, gave a deflection of the needle to the right or left, and uniformly for a given phase of change. It was, also, observed that the direction of the deflection was reversed when the flexible ring was turned the other side up.

(II.) The same flexible ring, used in the same way, but without the current through it, gave substantially the same results. Of course the ring was permanently magnetized, and the change might have been inferred.

(III.) As the same kind of motion, due to change of form, is taking place when a ring is vibrating at its harmonic rate, producing what we call sound vibrations, it was thought probable that a magnetized ring, having a coil of wire about it, in connection with a telephone, would set up vibratory currents when it was struck; and this was found to be true, for when the coil containing the heavy iron core was put in circuit with a telephone in another room, the sound of the stroke and the pitch of the ring could plainly be heard. In the first case, the number of turns of wire was small, perhaps fifty or thereabouts. I, therefore, had two larger rings made, each about one foot in diameter and half an inch thick.

(IV.) One of these was wound with six or seven hundred turns of No. 32 wire. Before it was magnetized it was connected with the telephone and tested for its magnetic condition by striking. The ring could plainly be heard, which showed that it had some degree of magnetism.

---

[1] Based on a paper read before The American Academy of Arts and Sciences.

(V.) Then, about two hundred turns of coarse wire was wound upon it and a strong current sent through it to magnetize it. After this magnetizing coil had been removed, the ring was again tested as in IV. The sound was very much louder. Indeed the telephone could be held a foot from the ear and be heard.

(VI.) With the ring in V still in circuit, the companion ring, without any wire upon it, was brought near it and struck. The sound was easily heard in the telephone circuit.

(VII.) This second ring was now magnetized in the same way as the first, when the magnetizing helix was removed, and the experiment VI repeated. The sound was *very* much louder.

(VIII.) The ring was now struck and moved away from the first ring by stages of an inch or two at a time. It was found possible to hear its pitch in the second circuit, when it was a yard or more away from it.

(IX.) As the pitch of the two rings was not quite the same, the higher one was loaded so as to bring them to unison. The sound was then louder and more persistent than before. This gave evidence that it was a case of sympathetic vibration, while the former ones were forced vibrations.

(X.) A common horse shoe permanent magnet, with legs about six inches long, had perhaps 50 ohms of No. 32 wire wound about the bend, and this was put in circuit with the telephone, as shown in Fig. 8, and struck like a tuning fork. The sound was remarkably loud. It was too strong to be held comfortably at the ear.

(XI.) A coil of wire was now put about the middle of a piece of gas-pipe, which was without permanent magnetism. The piece of pipe was about 4 feet long and $\frac{5}{8}$ of an inch in diameter. This, when in connection with the telephone, was struck two or three times a second, with a piece of brass rod, and while being thus struck, it was rotated from the magnetic meridian to a position at right angles to it. The difference in the loudness of the sound, between the position in the meridian and away from it, was very marked.

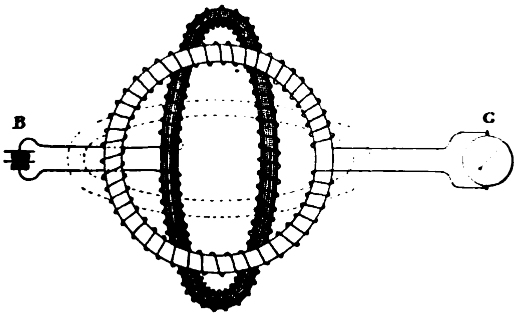


FIG. 6.

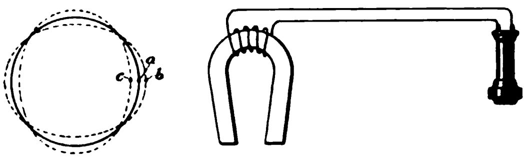
It is therefore shown to be possible to determine the points of the compass with a telephone, a coil, and an iron rod.

(XII.) A second flexible ring was now made, about a foot in diameter, consisting of a bundle of soft iron wire, the ends being roughly braided and twisted together, the thickness of this was rather less than half an inch. This was covered by a rubber tape wound spirally around it, the better to secure stability of form and isulation. Then 4.6 ohms of No. 21 wire was wound about it its entire length, making probably 1,000 turns. It was then magnetized by a current from 3 secondary cells having 6 volts, giving a magnetizing current of about 1,300 ampere turns, leaving it a ring magnet. The terminals were then connected with the terminals of a reflecting galvanometer with a resistance of .67 ohms. Very slight changes in the form of the ring, either by pulling or pushing, gave decided movements to the needle, while larger amplitude gave 30 to 40 degrees deflection.

(XIII.) It was noticed, also, that the direction of the current depended not only upon the direction of the motion changing the form, but also upon the direction of the motion with reference to the normal shape of the ring. Thus, if the ring be drawn into a horizontal ellipse, the current will move the galvanometer needle, say to the right. When it is brought back to the circular form, the circuit is reversed. If the motion be continued so as to produce a vertical ellipse, the current will be in the same direction as that produced at first by a motion exactly opposite in direction; so that for a complete cycle of vibratory changes, four currents are generated, two direct and two reverse. For instance, in Fig. 7, when a point *a* is moved to *b* the induced current may be direct, but it will also be direct if point *a* be moved to *c*, so that for the movement *a b c* there are currents that may be thus represented.



FIGS. 7 AND 8.

(XIV.) One of the iron rings, before mentioned, a heavy one about 8 inches in diameter and an inch and a half thick, having coarse wire wound upon it nearly covering the ring, was connected with the galvanometer as before, and the ring was struck by a brass rod. The needle instantly swung through a wide angle. Struck again, it moved as before but not through so wide an angle, and a half dozen blows knocked nearly all the magnetism out of the ring. This was then detached from the galvanometer and magnetized as before, when it again gave the same large deflection it gave at first. The same conditions were tried with other rings and in each case it was found that a vigorous stroke upon the ring magnet had the same destroying effect upon the magnetism, as it is known to have upon magnets having external fields.

The flexible ring was now put in circuit again, and vigorously jerked with the hands. A very few such movements served to destroy nearly all the magnetism present, requiring the re-magnetization of the ring.

As flexible iron rings such as I wanted were not easy to make, I procured some steel wire rope of the right size and the ends were welded for me through the courtesy of Prof. Elihu Thomson, of Lynn, by his electrical welding process. Such a ring, about a foot in diameter, allows a movement of five or six inches to one of its sides. This, when wound with four or five hundred turns of No. 22 wire may be magnetically saturated by sending a current through the wire, leaving the ring charged. The terminals may now be connected with a proper galvanometer, and changes in the form will discharge the ring.

These experiments prove:

1. That a change in the form of a magnet causes a corresponding change of stress in the field.
2. That periodic changes in form, due to elasticity of form such as are called sound vibrations, set up similar periodic changes or waves in the magnetic field.
3. That such sound vibrations of a magnet, act upon other magnets like sound vibrations and set them into corresponding vibratory movements, sympathetic or forced; sympathetic, when the receiving magnet has the same pitch as the transmitting magnet, and forced, when it has not the same pitch.
4. That such sound vibrations in the receiving magnet cause a corresponding change of form in its magnetic field, which manifests itself by electric currents in circuits surrounding it.

Sir William Thomson has frequently said that he could understand a mechanical idea when he could make a model of it, but could not otherwise. If one assumes that the ultimate atoms of iron are magnets, as is thought most probable now, or holds, by Ampère's hypothesis, that currents of electricity circulate about each one, making it a magnet,—in either case, each individual atom has its own magnetic field, which is, necessarily, always with it. It is really its reaction upon the ether. If such atoms be elastic, as there are the best of reasons for believing, then it follows that impact must set them into periodic vibratory motion, that is, periodic change of form at a rate depending upon their degree of density and elasticity. Such changes of form set up corresponding periodic waves in the ether, as changes in the magnetic field, and these are transmitted outwards, at a rate depending upon the properties of the ether to transmit such motions, and not upon the source of the disturbance.

Such vibratory motions among atoms and molecules we call heat, and such periodic waves in the ether, we call light, and thus Maxwell's idea of light being an electro-magnetic phenomenon is altogether in accordance with the experiments.

For waves of the lengths of light waves, it is essential that the vibrating body be small and highly elastic.

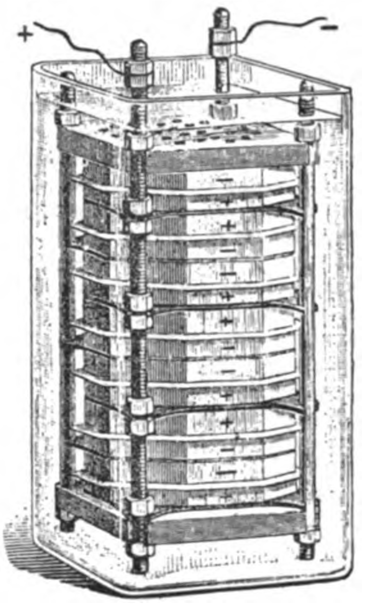
Maxwell's idea was that the opposite phases of ether waves could produce opposite electrical effects so that each half vibration represented either positive or negative conditions; and these implied, though I have not noticed the statement, that they must have originated with vibrating magnetic atoms or molecules. It has been difficult or impossible heretofore to imagine how ether waves could be set up by vibrations of the elements, though the idea that the atoms of matter are magnets is not new at all, and has a good degree of probability. If one is to picture to himself at all how this kind of a phenomenon can occur, he is bound to have in mind some form for an atom that shall, at the same time, be a consistent magnetic form. If atoms are magnets, it is well nigh inconceivable that they should be spheres, or cubes, or tetrahedra, or discs, or any of the ordinary geometric forms, for such would be very poor forms to exhibit magnetic properties. But a ring presents a very different case, as a ring magnet is the most perfect form possible. There is this to be said of such a form, however; it does not present what *we commonly call* a magnetic field; it is a closed circuit. Nevertheless, I would ask if it is probable that the ether, external to a magnet of that form, should be quite unaffected, quite neutral? I should suppose not, but, on the contrary, should look for some sort of stress there, though it might be of a somewhat different nature, and have somewhat different properties from an ordinary magnetic field. But if such were the case, it follows that any magnetic change in the ring magnet itself, would be followed by a corresponding change in the external field, and vibrating motions would necessarily set up waves in that field. Such waves would have a magnetic origin, but the waves themselves would not necessarily give rise to electro-magnetic effects directly. Indirectly they would, for if they could make another similar magnet vibrate sympathetically, these vibrations would react upon its magnetic properties.

Such a ring form as I have shown, suggests at once the Vortex Ring theory of atoms, the properties of which I have so often spoken upon in this place. Perhaps the experiments should have a different interpretation from that suggested here, but whatever their interpretation may be, they are believed to be entirely new, and therefore of interest, if not important.

Mr. Charles Francis Adams.—It is intimated by the New York *Journal of Finance*, that, upon his return from Cuba, at the end of March, Mr. Charles Francis Adams will become identified with the Westinghouse Company.

THE ATLAS ACCUMULATOR.

At a recent meeting of the Société Internationale des Electriciens, M. R. V. Picou read a paper on the "Atlas" accumulator, the outcome of the joint labors of Mr. Carl Hering and MM. Abdank-Abakanowicz, d'Arsonval and a Picou. Each element, as shown in the engraving, consists of pile of positive and negative plates separated by thin sheets of perforated indiarubber, thin sheets of lead being "sandwiched" in at intervals. The positives are of peroxide of lead, and the negatives of spongy lead, both being pierced with numerous holes. The pile of plates is kept in position, and electric connection is effected, by means of nuts and bolts of an alloy of lead, as shown, which are arranged to permit of expansion in every direction.



The Atlas Storage Battery.

The following are some of the data given by M. Picou:

Porosity of Plates . . = 50 per cent.
Density of Plates . . = 4
Capacity per lb. of plate = 9. amp. hours.
Discharging curreut . = .7 to .9 amp. per lb. of plate.
Dimensions of a 150 ampere hour cell . . = 6¼ × 7¼ × 13 inches.

In the course of his remarks M. Picou stated that he had found out experimentally that accumulators ought preferably to be charged at a constant E. M. F. of about 2.3 volts per cell. M. Hospitalier confirmed this statement.

ELECTRIC PREPARATION OF HYDROSULPHITE OF SODA.

Hydrosulphite of soda is a salt not much used in commerce; it is almost exclusively used in dyeing, either to lighten indigo tanks or to bleach silk or wool. It is almost always prepared by the Schützenberger process, which consists in making zinc react upon a solution of bisulphite of soda. These manipulations are long, and the cost is high. An electric process has been described by M. Villon, both more rapid and cheaper than the present one. The bisulphite of soda is reduced by the electrolytic hydrogen; 88 kilogrammes of bisulphite of soda, require to be completely transformed, three kilogrammes of hydrogen instead of two, the theoretic figure. The operation is carried out in a pine trough with porous earthenware divisions; one compartment contains the negative carbon electrodes in 300 litres of bisulphite of soda at 35 deg. Beaumé; the positive electrodes dip into a solution of sulphuric acid diluted with 10 times its volume of water. The trough is hermetically sealed, and the current is passed until four kilogrammes of hydrogen is formed. This operation takes 350 horse power hours. The hydrosulphite is then ready for use. The net cost of these 300 litres is 6f.

NOTES ON ALTERNATING CURRENTS OF VERY HIGH FREQUENCY.

BY

Elihu Thomson

THE interesting account of the novel experiments given by Mr. Nikola Tesla in the *Electrical World* of Feb. 21, 1891, and relating to the phenomena of alternating currents of very high frequency, lead me to make a statement of some of my own obervations while working in similar directions. The highest number of alternations which I have had at my disposal up to the present have been 8,000 to the second, a rate somewhat below that which Mr. Tesla has obtained, but which, nevertheless, shows properties and brings about actions and results similar to those which he described. The physiological actions of these rapidly alternating currents have been very ably investigated by Dr. Edward Tatum, some of the results of whose work I have presented in a separate communication.

Mr. Tesla's experiences in relation to the static effects of these currents of high frequency are similar to those noted by myself, particularly the small surface of the condenser which is able to transfer, or permit to be transferred, a considerable amount of energy through a dielectric, owing to the exceedingly high rate at which the changes of direction of charge are made.

The following experiment which was tried by me some months ago, is interesting in this connection. An incandescent lamp bulb was constructed, in which only a single platinum leading-in wire was used, on the end of which, inside the bulb, was mounted a single slip of carbon, two or three inches in length, it being one leg of a broken incandescent lamp filament. Two-thirds of the lamp bulb was now immersed in an outer vessel of water, leaving the single wire above the water for attachment to the source of alternating currents at one terminal, and the other terminal was connected with the outside water, which was rendered slightly conducting by salt dissolved therein. The water surrounding the lamp bulb formed, of course, an outer condenser coating, while the vacuous space and straight slip of carbon were the means for the conveyance of a charge to and from the inside surface of the bulb, which was, of course, exhausted to the ordinary vacuous condition, as found in an incandescent lamp. When an alternating potential of about 1,000 volts, and with a rate of alternations up to 5,000 per second, was applied to the carbon strip, the filament was brought to bright incandescence simply by the bombarding action of the residual gas, as in the Crookes tubes, while, of course, no complete circuit existed, the condenser action of the lamp bulb allowing sufficient current to flow. At the same time the glass of the lamp bulb not immersed in the water, became rapidly heated, indicating that that portion which was immersed in the water would have become equally heated had it not been subjected to the cooling action of the water itself.

The retention of the arc, as with direct currents, and the high note evolved by it, have been noted from the beginning of my experiments with these high period currents. Mr. Tesla expresses surprise that he was enabled to hear the note from an arc in which the alternations of current were more than 10,000 per second. Mr.Tesla will pardon me for calling his attention to the the fact that he is taking as the limit of audition in this case sounds from 5,000 to 10,000 complete waves per second, which is far below the limit at which sounds become inaudible to ordinary ears, cases existing in which a pitch corresponding to over 30,000 per second has been heard, according to some authorities.

The cause of the persistence of the arc with very high period alternations as stated by Mr. Tesla is undoubtedly the correct one, *i. e.*, that the gas stream has no time to cool between the alternations, and its variations of temperature must therefore be quite slight. The conductivity of the vapor or gas stream constituting the arc therefore remains nearly constant when the rapidity of alternations is sufficiently great.

The characteristics, stated by Mr. Tesla, as requisite to be possessed by machines suitable for obtaining constant current for the working of arc lights, are of course connected with the fact that in such machines the characteristic curve indicates a drop or fall in the electromotive force developed on a slight excess of current above the normal and, on a decrease of current, a raising of the electromotive force to a point above the normal.

It is not, however, in accordance with my experience, that the undulation of the current is almost essential to the success of an arc light system, nor do I think that properly constructed clutch lamps depend for their success any more than do finely constructed clockwork lamps, on the presence of a rapidly varying current due to a small number of armature coils and correspondingly small number of segments in the commutator. In fact, I have run with perfect success clutch lamps in circuit with coils of such large self-induction that any but very slight fluctuations were wiped out, and without introducing any particular difference in the behavior of the lamps. It probably is true, however, that slight gentle fluctuations occurring at very moderate intervals may be of benefit in the working of clutch lamps by keeping, as it were, the clutch mechanism in a state of vibration or tendency to open or close, but it can scarcely be doubted that if this benefit exists for such lamps a similar benefit would exist on the operation of clockwork lamps, as a similar fluctuation would give rise to a continual tendency in such lamps to keep the detent or escapement free enough for delicately letting-go teeth for the feed; but the fact that large numbers of lamps are in use in which the feeding of the carbon, either by clutch or by clockwork, is under the control of a derived circuit magnet only, and that such lamps operate with the greatest satisfaction, shows that the undulations mentioned by Mr. Tesla are not necessarily a factor to be considered. In such cases the self-induction of the arc branch is negligible as compared with that of the derived circuit magnet controlling mechanism, and the fluctuations therefore would pass through the arc without affecting the said magnet to a perceptible degree, particularly as the potential around the normal arc with slightly different current strengths flowing is nearly constant.

I may add that the experiments of Mr. Tesla in relation to the action of the condenser and the elevation of potential brought about by it are decidedly interesting and point to the possibility of obtaining a pure resonance effect. This would require, however, that the periodicity of the alternations be preserved very rigidly during the experiments, and involves the production of an unvarying or perfectly constant speed in driving the generating machine, a condition not easily obtained in practice.

In making the above notes on the highly interesting and valuable account given by Mr. Tesla, I desire to state that in whatever way my notes may appear as criticism of Mr. Tesla's views, they are not made in any unfriendly spirit, but with the desire of reaching the exact facts which it is the object of scientific investigation and discussion to ascertain.

SITES FOR CENTRAL STATIONS.

ACCORDING to the *Elektrotechnische Zeitschrift*, the simplest method of determining the best site for a central station will be to find the centre of gravity of the system, taking the values of various points in the area as proportionate to the density of current to be supplied at these points, in which case the total weight of copper in the feeders will be at the minimum. This calculation will, however, have to be modified when the considerations of cost of site and rent and, it may be, cost of cartage of fuel and so forth, are taken into account.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—XVI.

(*Copyright The Electrical Engineer.*)

BY

Herbert Laws Webb

CONNECTIONS OF PERMANENT SET OF TESTING INSTRUMENTS.

In Fig. 36 is shown a diagram of a complete lay-out of testing instruments for use in the testing room of a wire factory, electric-light, telephone or telegraph central station. The instruments required have already been fully described, and in describing the lay-out and connections it is only necessary to briefly enumerate them once more, as follows :

Astatic reflecting galvanometer with box of shunts, lamp stand and scale.

Galvanometer reverser.

Short circuit key.

Discharge key.

Battery reversing key.

Wheatstone bridge (for permanent use, preferably of the dial pattern).

High resistance box, 100,000 ohms or one megohm.

Adjustable condenser.

100 cell testing battery.

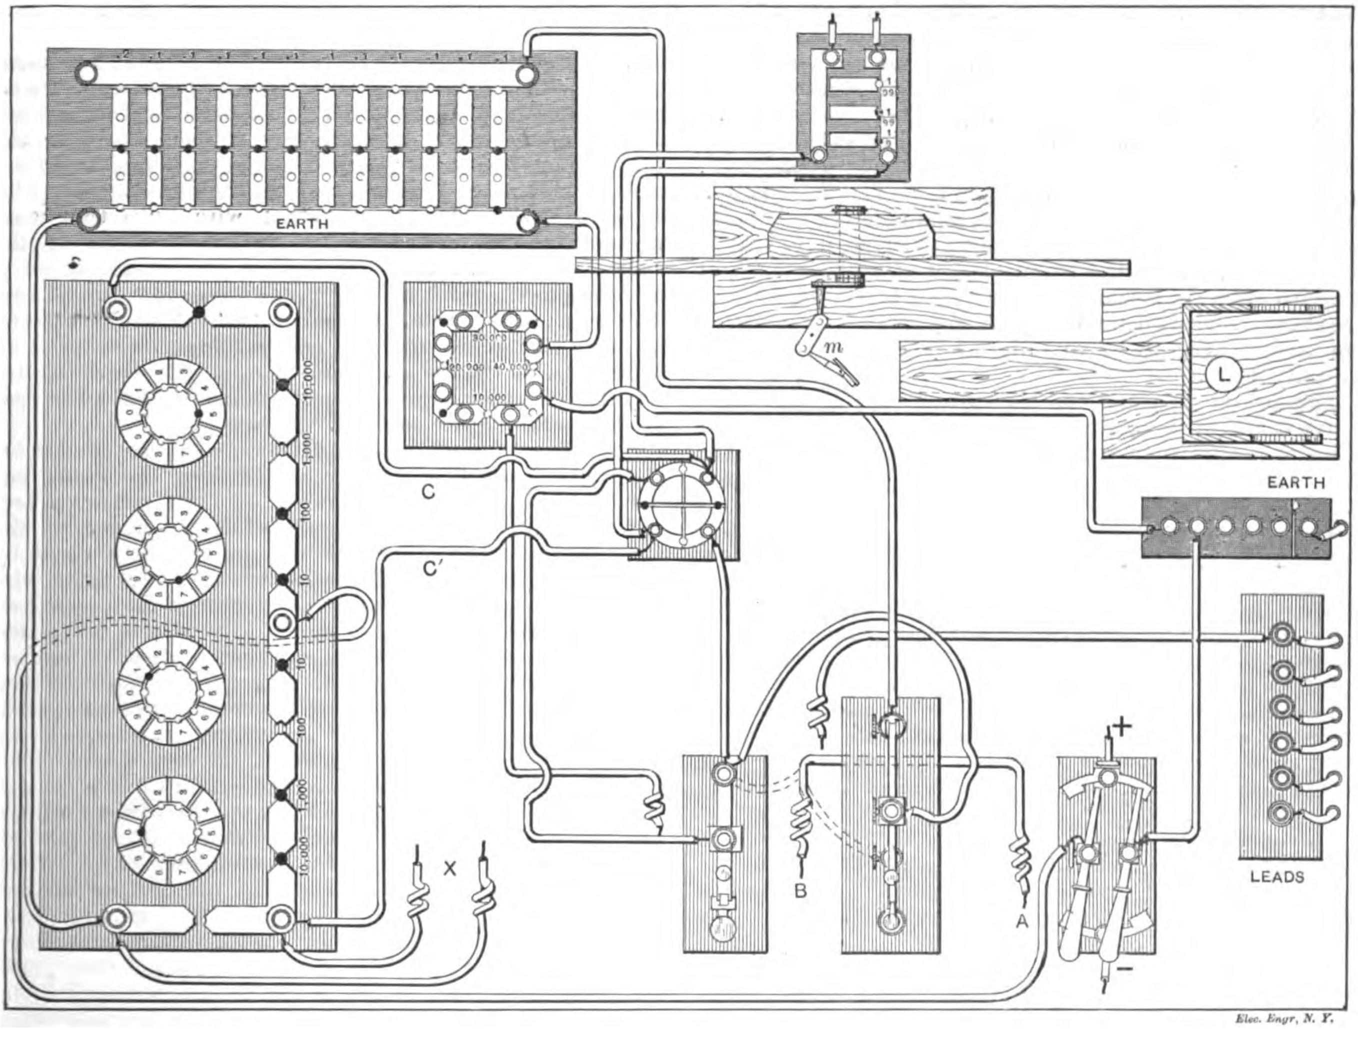
Set of insulated double binding posts for attaching leads running to factory or cable terminals.

Set of single binding posts on brass plate for earth connections.

In the diagram all these instruments are shown, with the exception of the galvanometer and battery; their positions, however, are sufficiently well indicated by the leads from the shunt and battery reversing key. The omission of the galvanometer and battery allows of greater clearness and compactness in the diagram. The diagram shows the most convenient method of placing and connecting the instruments on the table; the galvanometer would be set upon a shelf removed a short distance from the table and the battery on another shelf, either at the side of the manipulator behind the table, or underneath.

Starting from the right hand lower corner of the table, we find the set of insulated double binding posts on which the leads running to the cables are terminated. Immediately above this is placed the brass plate with a number of single binding posts; this plate serves for connecting the instruments together or connecting them to earth, a stout wire being run from the end post to a good earth. The improved form of plate is shown with the end post divided from the rest of the plate, so that the ground can be taken off by removing a plug. This arrangement is useful when testing a looped wire for copper resistance, as the presence of a ground will often prevent a balance being obtained.

Above the earth plate is placed the lamp stand, from which projects a wooden channel directing the light to the mirror at the back of the scale, by which it is reflected to



Elec. Engr, N. Y.

FIG. 36.—DIAGRAM OF COMPLETE LAY-OUT OF TESTING INSTRUMENTS.

the galvanometer. The scale is of the ground-glass pattern previously described. Next to the set of insulated binding posts is the battery reversing key, of the Rymer-Jones pattern. One pole of the battery is connected to each of the crescent-shaped contact pieces at either end of the key; the right hand lever is connected to earth by a wire run to the earth plate. Near the left hand lever two wires are terminated, being attached to the table and spiralled so that either can readily be connected to the binding post on the left hand lever. One of these wires goes directly to the centre binding post of the bridge; the other is terminated between the short circuit and discharge key, and spiralled so that it can be connected to either key—to the short circuit in taking the galvanometer constant, or in testing for insulation; and to the second for capacity tests. So much for the battery connections.

Next to the battery key is placed the discharge key, and next to this the short circuit key. The short circuit key is permanently connected to the galvanometer reverser by two wires, and a short wire is run from one post of the short circuit key to the upper contact of the discharge key. At the back of the discharge key is terminated a wire from the condenser, which can be connected to the lever of the key for taking the discharge of the standard condenser. In the same manner a wire from the high resistance is terminated near the short circuit key, available for being connected to the binding post of the key opposite to that to which the wire from the battery key is attached. A short wire led from the insulated binding posts to a point between the short circuit and the discharge key serves for connecting any of the leads to either key for insulation and capacity tests.

The bridge is placed at the extreme left of the table; above it and at the rear of the table is the multiple-series adjustable condenser, and in the angle between the two the high resistance box used for taking the galvanometer constant.

We have already seen that one wire runs direct from the battery key to the centre binding post of the bridge, another wire from the discharge key to the condenser, and still another from the short circuit key to the high resistance; the other connections of these instruments are as follows: From the extremities of the bridge arms two wires are led to the galvanometer reverser, and spiralled so as to be readily attached to opposite segments of the reverser. It would be the same thing to take these wires to the short circuit key; but as this would overcrowd the wires in that neighborhood, it is more convenient to take them to the reverser.

To connect the unknown resistance to the bridge, two wires are led from the binding posts on the brass blocks at the left of the bridge; the infinity plug being out, one of these posts constitutes the extremity of one of the proportional arms, the other the extremity of the adjustable resistance coils. The two wires are preferably taken to the extreme right hand corner of the table and terminated and spiralled there, ready to be connected to a pair of the leads attached to the insulated binding posts. For greater clearness they are shown in the diagram just to the right of the bridge at x, as if for connection to a coil whose resistance is to be measured. The remaining connection of the bridge is from the end of the adjustable coils to earth or to the second pole of the battery; the condenser and high resistance also require to be connected in the same manner; and to simplify the wiring, a wire is run from one of the binding posts of the high resistance to the earth plate. The extremity of the bridge coils is connected to the "earth" block of the condenser, and this, in turn, is connected to the high resistance by another short piece of wire. In this manner the return circuit of the bridge, condenser, and high resistance, is effected with the greatest economy of wiring and connections.

The usefulness of the earth plate here shows to advantage: one lever of the battery key being permanently connected to it, the connections to one side of the other instruments can also be made permanent, and the plate serves both as a junction for the bridge, condenser, high-resistance and battery wires, and as a handy connection to earth whenever such a connection is required.

The galvanometer reverser is permanently connected to the shunt, and the shunt to the galvanometer. The position of the shunt is a trifle inconvenient, but it is best placed as near as possible to the galvanometer, or error may be introduced by the resistance of the leads between the shunt and the galvanometer. In any case, very thick leads should be used for this purpose.

The lay out of instruments and connections described above will be found very convenient for arranging a set of instruments for permanent use in one place. A table four feet by three accommodates the entire set, as shown in the diagram, a clear space being left between the short circuit key and the bridge, for placing the note book or test-blanks.

The diagram shows the instruments connected for measuring conductor resistance; as will readily be seen, the alterations to be made, in order to connect the instruments for any of the other tests, are very simple. To take the galvanometer constant the bridge wires are removed from the galvanometer reverser, and the bridge battery wire from the battery key. The short wire A B is then connected to the battery key and to the rear terminal of the short circuit key, the wire from the high resistance being attached to the front binding post of the short circuit key. The connections for taking the constant are then complete; the only change required to connect for insulation is to substitute, on the front binding post of the short circuit key, the short wire running to the leads for the wire connected to the high resistance.

To connect for taking the discharge of the condenser, the B end of the wire A B is removed from the short circuit key to the underneath contact of the discharge key, and the condenser wire is connected to the lever of the key. The short circuit key is held permanently open by the catch, thus insulating the contact, and the short wire which joins the two keys serves to connect the upper contact of the discharge key with one wire of the galvanometer. The other side of the galvanometer must, of course, be connected to the earth plate, and this is done by running a temporary wire from one segment of the galvanometer reverser to the high resistance, which, as previously shown, is permanently connected to the earth plate. This completes the connections for capacity, and to take the discharge of the cable merely requires the connection of the piece of wire joining the lead to the rear binding post of the discharge key, in place of the condenser wire. With the instruments and connections laid out in the manner shown and described, the changes from one test to another can be made very quickly and without any confusion. Most of the wires are fastened to the table, but some, such as the wire from the discharge key to the condenser, and those from the bridge to the condenser, battery and leads, can be carried underneath the table, or under the projecting ledges.

NATURAL GAS DUTIABLE.

A Washington despatch says: "The Assistant Secretary of the Treasury has approved the action of the Collector of Customs at this port, in exacting duty on the natural gas imported from Canada." The gas people are stirred up and claim the decision of the Department is incongruous, in that electricity for lighting purposes is permitted to be imported across the Rio Grande from Mexico without the payment of duty. A very nice question is involved, and there will either be a change in the Department's action or an electric plant will be established in Canada near Fort Erie, where natural gas will be turned into electricity and brought across the river free of duty. It is reported here that one of the big electrical companies is making arrangements to establish such a plant near Victoria.

BOTTOME'S ASYMMETRICAL ELECTRICAL RESISTANCE.

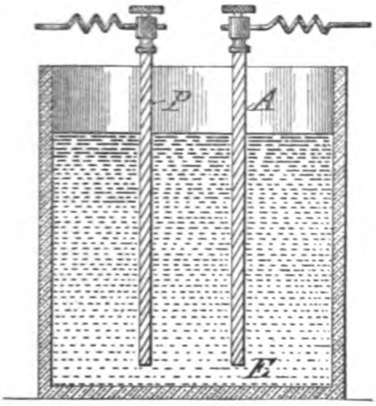
The accompanying illustration represents an "asymmetrical" conductor recently devised by Mr. Turner D. Bottome, of Hoosick, N. Y., for the purpose of directing alternating currents into currents of a continuous nature, suitable for energizing the field magnets of alternating current dynamos, and for electrolytic operations, etc.

As shown in Fig. 1, A is a conducting plate composed of aluminum. P is a conducting-electrode composed of platinum, carbon, or other inoxidizable element.

The fluid conductor is not intended to perform the office of an excitant, but merely that of a medium, and may be liquid, jelly, or semi-solid.

When the electrode A is electrically connected to the positive pole of an electric generator supplying a continuous current, and the electrode P attached to the negative pole, upon passing a current for a very short period of time, no unusual resistance will be offered by the device to the passage of the current; but upon reversing the direction of the current and passing it as before for a very short period of time, it is found that only a small portion of the original current passes, owing to the high resistance the device offers to the current in that direction.

The action taking place during this operation is supposed to be due largely to the peculiar nature of metallic aluminum under electrolytic action, and to the possible formation of a basic aluminum oxide of insulating properties upon the aluminum plates when the current passes in one direction, and the decomposition of this oxide into a soluble sulphate when the current is passed in the other direction.



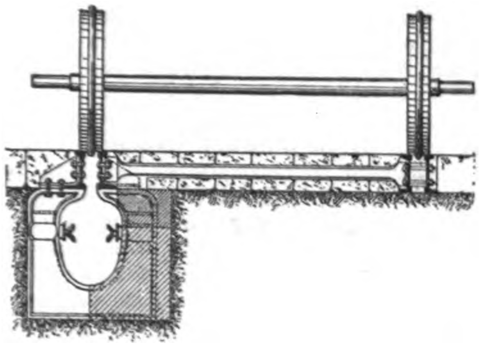
Bottome's Asymmetrical Resistance.

Being thus practically impervious to currents of one sign and permitting those of the opposite sign to pass, the arrangement, it is claimed, can be employed to sift out the varying impulses of the alternating current, allowing only those of one sign to pass, so that continuous currents of one direction can be obtained from an alternating current circuit.

THE BUDA-PEST ELECTRIC RAILWAY CONDUIT.

The continued success of the electric railway at Buda-Pest, in Hungary, equipped with an underground conductor system, by Messrs. Siemens & Halske, is attracting considerable attention to this system, both here and abroad. The track in that city is formed of one Haarmann rail and one slot rail. Under the latter is the concrete conduit, 11.2 ins. wide and 13.2 ins. high. Iron yokes are placed under this rail every 3.9 ft. The conductors consist of two small angle irons, one on each wall of the conduit, and at such a height that they are out of the way of water and dirt. The slot is 1.3 ins. wide and acts as a guide to the wheels on one side of the car as well as an entrance for the trolley rods. The lines include nearly 5.15 miles of both single and double track, and have been operated more than a year. The rolling stock consists of 50 motor and 8 trailing cars, which differ in few respects from those built in this country.

The construction here adopted will recall to our readers strongly the conduit system long since advocated by Mr. Stephen D. Field in this country. He designed such a system, with a conduit, the top of which formed the rail for the car to travel on, and worked out full details, such as are illustrated in the accompanying engraving.

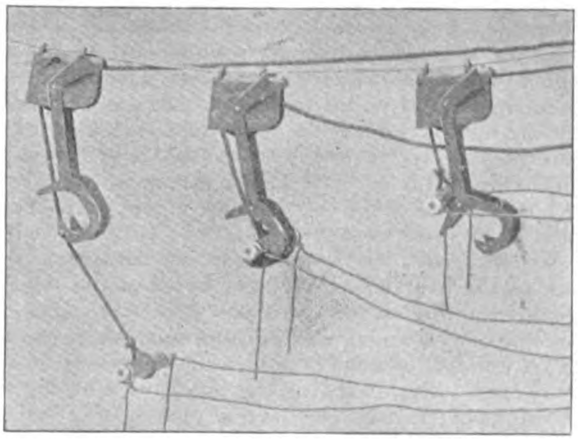


The Buda-Pest Electric Railway Conduit.

AN AUTOMATIC ARC LAMP REST.

The accompanying illustration represents a device invented by Messrs. Danals and Perry, of Zanesville, O., designed to allow an arc lamp to rest, when in position, so that there is no strain upon the rope, which is then only brought in use when the lamp is being raised or lowered. The engraving shows the lamp rest in three different positions, illustrating its simple construction and action.

The view at the left shows the lamp when being raised into position; that in the centre shows it hanging in the rest, with the lifting rope slack; while at the right is seen the lamp, lifted above the controlling fingers, preliminary to lowering; when the lamp is now lowered, the fingers push the hook back entirely clear of the lamp arm, so that the lamp is free to drop.



Danals and Perry's Arc Lamp Rest.

The rest can be attached to any pulley by simply taking out the rivet, and replacing it by a $\frac{5}{16}$ inch bolt extending through both pulley and rest. More than a hundred of these lamp rests are in use in Zanesville, where they are giving excellent satisfaction.

PHYSIOLOGICAL EFFECTS OF ALTERNATING CURRENTS OF HIGH FREQUENCY.

BY

Elihu Thomson

In connection with an experimental investigation of the properties of alternating currents of high frequency, and the phenomena which they present, it had occurred to me that it would be desirable to obtain data concerning the physiological effects of these currents as compared with the effects of currents of ordinary frequency. I had constructed a machine on the type of my new alternating dynamo, accounts of which were published some time last year.[1] In this machine an iron mass only is revolved, the central portion of which carries projections which pass near to the coils in which the currents are induced, which may be termed the armature coils, carried on the inner face of a laminated structure, and in turn supported by the outer framework of the machine. The machine with 100 armature coils and a speed of 5,000 revolutions per minute gives a little over 8,000 alternations per second.

The publication of brief notices of some of the results obtained in the operation of this machine led Dr. Edward Tatum, of Yonkers, N. Y., to correspond with me with the view of finding out whether I had intended to conduct any physiological experiments with the currents, and indicating his desire to experiment in this direction if the machinery for obtaining the currents could be placed at his disposal for a short time. Accordingly the machine was sent to Dr. Tatum some time last fall and was used by him in making a series of experiments, the results of which can not fail to be of the highest interest to electricians and physiologists. Very unfortunately Dr. Tatum has been an invalid since January last and has therefore been prevented from writing up the results which he obtained, some of which were transmitted to me in a letter dated December 29th, 1890, before he was taken sick. I will premise by saying that Dr. Tatum had intended to continue his experiments further before publishing any results of the trials. I quote from Dr. Tatum's letter as follows:

"The most definite and perhaps the most striking, as well as physiologically instructive, result has been in regard to the fatal efficiency of such rapidly alternating currents. When the circuit is formed through the head and body (of dogs) death occurs in the same manner as with other sources of current (which are made strong enough to kill by a closure lasting not more than two or three seconds), that is, by primary arrest and paralysis of the heart. But taking the fatal efficiencies of different sorts of currents as inversely proportional to the current strengths required to kill under otherwise similar conditions, a rate of 4,500 per second is not only far less efficient than rates of a few hundred, but it is distinctly less efficient than a continuous battery current. Indeed, in four of the five dogs that I have killed at the high rate a stronger nominal current was survived than I have ever before used (with a single irrelevant exception) to kill a dog. A nominal current of 1.35 ampere was entirely recovered from; the animal on the following morning showing no signs of physical or mental disturbance. This is four times the strongest fatal current at 300 alternations that I have used on normal dogs; six times the strongest current survived, and thirteen times the weakest fatal current. It is thirteen times the strongest fatal current used at 120 alternations; 20 times the strongest current survived, and eighteen times the weakest fatal current. It is remarkable that rates of 300 and of 120 alternations per second are fatally efficient at very nearly the inverse ratio of the numbers; but still more remarkable that the very highest rates should also present a strikingly near approach to a similar ratio. It must be noted, however, that no such ratio can hold throughout the whole range, for 36 alternations per second (from the same machine as furnished 120 and the 300 rates) are again distinctly less efficient than 120, something like two-thirds as efficient."

Dr. Tatum goes on to point out that a potential of 450 volts was survived at the high rate of alternations and the fatal current reached only at 495 volts, while 45 volts at 120 alternations similarly applied to the dog suffices to pass a fatal current.

Dr. Tatum also determined the ratio of pressure or potential to current in the dog just after the cessation of respiration, using in rotation, twice repeated, first, a continuous pressure or potential, secondly, an alternating one at a rate of 120, and, thirdly, an alternating potential at a rate of 4,500 per second at about 100 volts, and states:

"This ratio was so uniform (the extremes observed differing by less than 3 per cent.) as to dispose of any suspicion that the high period currents distributed themselves essentially different from others in the animal's body."

I will continue to quote from the Doctor's letter, as the results he obtained could not be so well expressed by myself as he has done in relating them:

"In regard to the physiological, as distinguished from the fatal, characteristics of the high period machine, I am only able to state the results in terms of pressure, instead of terms of current, as I should prefer. The limits of voluntary toleration for alternating pressures (applied with sponge electrodes) seems to depend very little on the frequency of alternation. For all the frequencies I have mentioned the limit has been found between 10 and 15 volts for applications about the face and head, and between 40 and 50 volts between the hands—without any decided preference in either case for one rate more than another.

"The cause of the pain which limits voluntary toleration seems to be in all cases chiefly in the muscular contraction produced. At 4,500 this muscular contraction is usually free from the thrill experienced even at 300; resembling, on the temples, nothing I can think of so much as firm pressure with the knuckles.

"The cutaneous nerves are distinctly less painfully affected at the high rate.

"The visual mechanism can not be excited at the high rate even by a pressure of 15 volts, so as to cause a sensation of flashes of light, although two or three volts similarly applied at 120 alternations causes such flashes very energetically.

"The sensation of dizziness caused by a few (four or five) volts applied behind the ears at a low rate of alternation of current can not be produced at the high rate.

"Sensations of taste are also absent.

"Directly applied to the exposed motor nerves and muscles of dogs and frogs, pressures at high frequencies seem less efficient as stimuli than at lower frequencies, in something like the same ratio as their killing power.

"The establishment of anything like an exact ratio I have not accomplished, owing partly to the very low pressures, which acted as very energetic stimuli when applied directly to fresh nerves. Thus a nominal potential difference of 1-20th of a volt in a length of nerve of 8 mm. of a frog's sciatic nerve still causes vigorous reaction. As the portions lose their vitality, however, stronger and stronger stimuli become necessary to elicit a response, and it is during this period of failing vitality that something like the above proportion is indicated between the respective pressures required to just produce a visible reaction."

Dr. Tatum's letter also contains references to the work which he had planned to carry out in the near future concerning the relations of alternating currents of high period to vital structures, which work he has been, I regret to say, prevented from pursuing by sickness, from which he has not yet recovered.

---

[1] See The Electrical Engineer, July 30, 1890.

He also makes the inquiry as to the practicability of constructing a machine to deliver currents at a rate of 40,000 to 50,000 per second, such machine to be used in continuing the investigations, some of the results of which are given in his letter.

I take great pleasure in being of service to Dr. Tatum in presenting some of the results of his very able investigations, feeling sure that they can not fail to be of the highest interest to physicians, electricians, and many others. In presenting these results, I take occasion to express my sincere regret that ill health has prevented the continuance of the work in the direction laid out by the Doctor himself, and to express also the hope that he may be able to take up the further investigations at some future time.

ELECTRIC RAILWAY GUARANTEES.

BY

C. H. Radbourne

"For how long will you guarantee your armature?" "How long will you guarantee to keep the motor in repair, gears and all?"

These, or similar questions, are a bugbear to the salesman who is trying to prove the superiority of his system of electric traction to the wise manager of a street railway company. How many times I have heard them, and how many times I have wished he would not ask them.

At first sight it seems a reasonable question, and the remark, "If your company has any faith in its motor, why don't it guarantee it," is a "sticker," and apparently perhaps your inability to answer it is a negative confession that your motor will not stand a guarantee.

From all I can learn, no company to-day absolutely guarantees its apparatus against everything and anything, and yet street railway men will hang upon that clause and make life miserable while they tell you about the "sweeping," iron-clad guarantee the other fellow, your competitor, has just written in his proposal. This has been a serious question perhaps with some companies. Large contracts have been pending, and the question of "guarantees" alone was the straw or weight, as the case may be, that would turn the entire contract one way or the other.

Ought an electric company to guarantee its dynamos and motors, and if so, to what extent? If you do wish to give a guarantee, what shall be the limit, and if your competitor goes you one better, is it good business policy to break your rules and "see him" in order to get a contract?

The argument is brought up that elevators, steam engines, boilers, mowing machines, and what-not, are absolutely guaranteed for one year, and "Why should you refuse to guarantee your armature if it's any good?"

It seems to me that this question is an important one, and while it concerns each company individually, it certainly affects them all. In the first place, the question of guarantees is not a matter of much importance as relating to the stationary motors running by the hundreds in every city and town, but on the crowded street car it becomes worthy of attention. As far as dynamos for lighting and power are concerned, they come under the same head nearly as stationary motors and are more easily rated. I suppose any of our leading companies that have hundreds of dynamos in operation could tell you exactly how much the average depreciation and repairs have been, and I should be surprised if the repairs on, say, 500 of any first-class make of dynamos scattered all over the country would average 2 per cent. per annum. Absolute figures or data on motors used in street car traction are hard to obtain. So many repairs are done by the roads themselves, and so much fixed up anyhow in local machine shops, that it is extremely difficult to get at the real cost of repairs on any road.

Suppose we are asked to supply a road with, say, four 100 h. p. generators and 50 cars to be operated under normal conditions, and to state the cost of keeping the same in repair, guarantee them, etc., what shall we say? I do not believe that, in the present state of the art, any men can foretell what the cost of keeping up such a road would be within 10 per cent.

I have in mind a road that was equipped with old style motors some years ago that are running yet, as *good as new;* for three years their repairs have been practically nothing. The road has long heavy grades, the cars are crowded, *but the motors are kept as clean and well oiled as a watch.* Lift up the trap door any time, and you will see the motors as clean and bright and fresh as the day they were put in, years ago.

How many roads can show such a record? Come with me and I can show you a road somewhat similarly situated, with the same motors, and practically the same grades, which has been running about the same length of time. Look at these motors! There, they are unprotected, *covered with grease and mud,* grounded in a dozen of places; *oil and copper dust ½ inch thick all over the brush-holders,* commutators worn out and brushes set at any angle, and with tension enough to cut a bar of iron.

See the difference! One road has a wide-awake, intelligent superintendent; the other is left to look after itself.

In answer to the question, then, we can say, "First guarantee the superintendent before we guarantee our machinery."

Still another important matter remains. Granting the superintendent and his assistant are all that could be desired, even then, I say, "Don't guarantee everything absolutely."

Is it to be supposed that any steam engine builder would make an engine with moving parts no larger than a 4 inch armature pinion, making 1,200 revolutions per minute, transmitting 15 horse-power, and then place this engine where sand, water, and mud would be poured over it constantly, combined with a constant bumping and jolting, and then guarantee it *for 15 minutes?* No, he would not, and he would not be expected to, either.

I don't care how much work is put on the manufacture of a motor, if you put it under the car in dust, dirt, water, and sand, it can't wear for ever, and the chances are if it is not guaranteed it will be kept with greater care, than if it is understood "the electric company pays the bills."

Instead of guaranteeing the motors, let us instruct the men more carefully in their use. Candidly tell the manager that your motor must be kept clean and as dry as possible. Don't be afraid to tell him that your motor needs attention and proper care. He will thank you for it. There is no place where a stitch in time will save more than on an electric motor.

As far as dynamos and stationary motors are concerned, that problem is an easy one, and that brings me to my hobby, if I have one, viz., the motor car, with the motor above the axles and car floor, in a warm dry room free from dust and moisture, the gears all boxed in, the whole equipment where it ought to be, high and dry, under the eye of the motor man.

When you see a road with 50 motor cars, such as I describe, hauling open and closed cars behind them, I believe you will see a road that gives nearly perfect service, and on which the repair and guarantee question will bother no one.

ELECTRIC MOTORS TO RUN EXHIBITS IN COURT.

A one horse power slow speed Crocker-Wheeler motor was wired up in the U. S. District Court, Post Office building, recently to run a Lynotype to show its workings in a patent suit. The motor elicited much favorable comment and was handled by the judges. It is a pity the judges could not make the electric motor's closer acquaintance during the hot days of summer.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XI. NEW YORK, MARCH 11, 1891. No. 149.

Great power in the hands of ignorant or careless men implies great danger. Sleepless vigilance is the condition under which we wield all the great powers of modern civilization.—Josiah Parsons Cooke.

THE HIGH SPEED ELECTRIC RAILROAD.

THE admirable simplicity and economy of electric street railroading has already been so thoroughly demonstrated that electrical engineers not unnaturally are carrying the work forward to an extent which could hardly have been anticipated but a short time back. The simplicity of mechanism and the total absence of all reciprocating parts makes the electric motor peculiarly adapted to the operation of a high speed car, and to these features its decreased weight, in comparison with the steam locomotive, lends additional value. The experiments inaugurated by Mr. David G. Weems, at Laurel, Md., have, we believe, completely demonstrated the practicability of obtaining speeds which have not thus far been attempted in steam railroading. They have shown, above all, what the power required for this class of work is, and especially that necessitated by the high air resistance encountered. In the very interesting paper read by Mr. O. T. Crosby, before the American Institute of Electrical Engineers, we find an interesting résumé of experiments made to determine this point, which shows that under the conditions existing at Laurel, Md., the atmospheric work almost equaled the effort required for acceleration, and, that, omitting acceleration, at 100 miles per hour, the atmospheric work was something more than one-fourth of the whole. Based on the results there obtained, Mr. Crosby shows in what manner a system can be worked out for actual commercial traffic. As a departure from the general run of electric railway work, his figures present many interesting points of comparison. It is to be hoped that the capital required to demonstrate the practicability of the methods suggested may soon be forthcoming, and we believe, indeed, that that time is not very far distant.

MAGNETIC MOLECULAR VIBRATION.

THE theory of magnetism which has especially during the last ten years been the subject of much research seems to be gradually but surely drifting towards that one in which all phenomena must be explained on the assumption that a magnet is built up of magnets of molecular proportions and the action and interaction of which result in the phenomena which we observe. Many experiments have already demonstrated the change in mechanical form produced in iron and steel by a change in their magnetic conditions, such as their elongation and subsequent contraction; and by applying an inverse process of reasoning, Prof. Dolbear now shows in our columns, this week, that a change in mechanical form gives rise to a change in the magnetic conditions. As a result of these experiments he throws out the suggestion that magnetic molecules may be of the ring form, and thus brings the phenomena in close relationship with the vortex theory of atoms. The assumption of the ring form for a magnetic molecule makes it difficult to reconcile this theory with the observed phenomena of magnetic polarity, but Prof. Dolbear suggests that the ether external to the magnet may act as the medium for obtaining the effects of external magnetism.

Prof. Dolbear also carries out the interpretation of his experiments another step and offers them as an answer to the question as to how vibrating molecules set up in ether the waves which we call light. This point has never before been made perfectly clear, and therefore must be deemed one of the greatest importance in physics. Whatever the interpretation attached to these beautiful experiments, they can not fail to add another link to the chain of reasoning that leads to a final theory of magnetism.

ELECTRIC RAILROAD GUARANTEES.

IT is but natural to suppose that the purchaser of any piece of machinery will deem the question of its life and freedom from repairs one of the most important, aside from the question of efficiency, and in this respect street railway companies do not differ from the rest of mankind. Indeed, knowing them to be the conservative body of men that they are, we are inclined to think that they are, if anything, a little more inclined to investigate and diagnose all the merits of the apparatus which they use, than is generally the case. It is not to be wondered at, therefore, that when a railway company is about to purchase electrical apparatus, one of the main questions entering into the negotiations is the life of the motors and the repairs which they will require. The question of what the guarantee shall be in this case is very ably discussed in another column by Mr. A. H. Chadbourne, who takes up both sides of the question, and, we think, finds the true solution for this vexatious problem. It has come to be generally recognized that even automatic machinery of the highest order requires more or less personal supervision for its proper operation. What then, as Mr. Chadbourne points out, can any guarantee of electric railway apparatus amount to, when the latter, normally subjected to the hardest kind of work, is not kept in proper working order? Although companies operating electric railways have not yet by any means generally adopted the practice of employing competent electrical engineers to supervise their apparatus, it is only a question of time when such will be the case. No matter how well the apparatus may be designed and operated, none but the most intelligent supervision can maintain it in proper working order, and the sooner this is recognized the better for both the seller and the purchaser of electric railway apparatus. We believe that in this respect the manufacturers of electric railway apparatus can do much, not only to lighten their own burdens, but to place electric railroading in the position it ought to occupy, namely, beyond the criticisms which are brought about by sheer neglect of the most ordinary precautions. Mr. Chadbourne, it will be noted, still favors the idea which was early applied in the art, namely, that of placing the motor on the car platform, away from the street bed and completely protected from all disturbing influences. This method undoubtedly has advantages in a certain direction, but the question of the method of gearing the armature to the axle was, we believe, the chief difficulty to contend with in this arrangement and it finally led to the adoption of the means now in general use for that purpose. But the objections which have been raised against placing the motor under the car have been largely removed by the adoption of motors and gears which are entirely enclosed.

ALTERNATING CURRENTS OF HIGH FREQUENCY.

It has more than once been suggested that if we could but construct an alternating machine capable of giving us a frequency of alternations approximating to that of light we should be able to obtain luminous effects without the accompaniment of heat, and thus obtain an ideal method of illumination. Unfortunately, the limits of the strength of materials, and of the mechanical and electrical means at our disposal, have thus far made the realization of this suggestion impossible. Recent experiments have shown, however,that even with a frequency of alternation far below that assigned to the light producing waves, important luminous phenomena are observed, and in a recent article Mr. Nikola Tesla gives the results of some remarkable experiments effected with an alternating current of 20,000 reversals per second. In these the condenser action of lamps and conductors is very forcibly brought out, and points to the fact that the condenser will play an important part in the methods of distribution of light in the future, if not, indeed, of power. Referring to the same subject, Prof. Elihu Thomson, in our columns this week, gives results of experiments made in the same direction, which cannot fail to to draw attention again to this subject, and which, taken in connection with the recent inaugural address of Prof. Crookes, illustrate forcibly the tendency of modern work in the attempt to obtain light without heat. Prof. Thomson also contributes a valuable note on the physiological effects of alternate currents of high efficiency, in which it is shown that at very high rates the current is less dangersou than at the lower rates now in vogue.

EUROPEAN ELECTRIC RAILWAY PRACTICE.

Electric railroading may, we think, justly be called the product of American genius and labor, and this belief is confirmed by the general adoption of American devices in the construction of similar apparatus abroad. Heretofore, our kin and friends across the sea have adopted arrangements which have already proved successful with us, but in some recent work they may be said to have gone a step beyond our own practice and put into practical operation methods that have been suggested here, but which, up to the present, have not gone into practical operation. We are led to this observation in contemplating the methods adopted in the construction of the Buda-Pesth conduit railroad. As stated in another column, the design here approved is essentially that advocated by Mr. Stephen D. Field, some years ago, and its successful operation is, we think, a good indication of the soundness of Mr. Field's ideas on this subject. It is to be hoped that some of our own roads may take up this method at no distant day.

Re-Starting of the Deptford Station.

The unfortunate interruption of the work from the Ferranti station at Deptford, some three months ago, due to a fire at one of the distributing stations, caused by a very careless workman, called forth, as might have been expected, some unfavorable comment at the time, but no one who is at all acquainted with Mr. Ferranti or those connected with him, can for a moment have doubted that in a comparatively short time the damage would be repaired, and the station be again in full operation. This has already come to pass. The station, as we note by English exchanges, has been started up again, and will, no doubt, successfully perform the work for which it was designed. The character of the work planned, and now being carried out by Mr. Ferranti, is such a radical departure from previous practice that it is to be expected that obstacles will be met with and new phenomena developed which have heretofore not come under the observation of electrical engineers, and for which, necessarily, no provision could be made; but once their nature is ascertained, a remedy must follow as a natural course, and thus the work will be carried to a successful consummation.

Municipal Ownership of Subways.

The question of the municipal ownership of subways has been brought up in New York by the proposition to wipe out of existence the old Board of Electrical Control, create a new Commission, authorize the spending of $3,000,000 of city money yearly on municipal subways, and supersede by purchase, or compensation, the subway system now operating. There are merits in the plan, but one always feels slow to approve any scheme that adds to the means of expenditure and sources of income under political management or control. What is really wanted is a plan of common subway construction that will give everybody a chance to run wires under proper rules and at a fair rental, and will prevent the streets from being in an everlasting state of upheaval and blockade. But to reach this end it is not necessary that the city should invest taxes in the work.

REPORT OF HIGH-SPEED ELECTRIC RAILWAY WORK.[1]

BY O. T. CROSBY.

THE experiments here reported were the first serious efforts ever made to at once double railway speeds, and as such should, I think, be systematically recorded.[2] They were made for the Electro-Automatic Railway Co., of Baltimore, Md. This company was organized about four years ago by Mr. David G. Weems, who, though not an engineer, was convinced that the electric motor would give very high speeds for the transportation of parcels. His persevering enthusiasm resulted in inspiring a number of gentlemen to subscribe money for the venture.

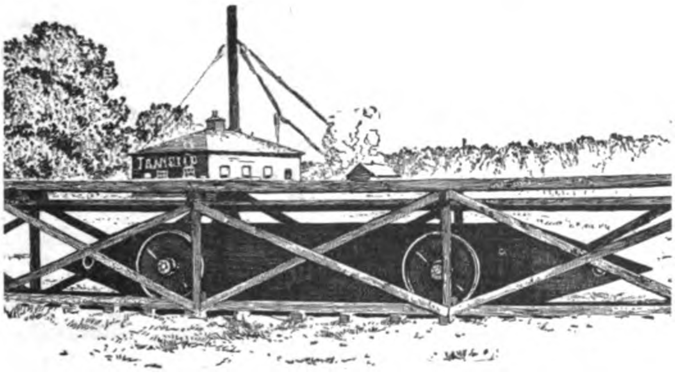

FIG. 1.—THE WEEMS HIGH SPEED ELECTRIC RAILWAY, AS OPERATED AT LAUREL, MD.

Mr. Weems first contemplated having an entirely automatic service from city to city, the cars to be smaller than would be necessary for placing a man. The experimental motor and track are shown in Fig. 1.

For purpose of demonstration, a circular track nearly two miles in circumference, was laid at Laurel, Md.; gauge, 28 in.; weight of rail, 16 lbs.; shape, **T**; cross-ties, 3x4 in. square, 16 ins. apart. Wooden stringers 3x4 ins. were laid outside each rail, serving as guards. Mud-sills 3x4 ins. were laid under the ties, and to the ties was built up a vertical frame-work on both sides of track, this carrying from 2x6 in. cross-pieces a wooden stringer, suspended above the middle of the track, while to the lower surface of the stringer was attached a small **T** rail, head down. This upper rail was intended to serve as an electric conductor, and also, in connection with upward pressing wheels, as a guide. The latter function was not successfully performed, the lateral oscillation of the car, on so slight a track, being too great. Part of the track was on trestle-work crossing a swamp, the overflow of which caused frequent wash-outs.

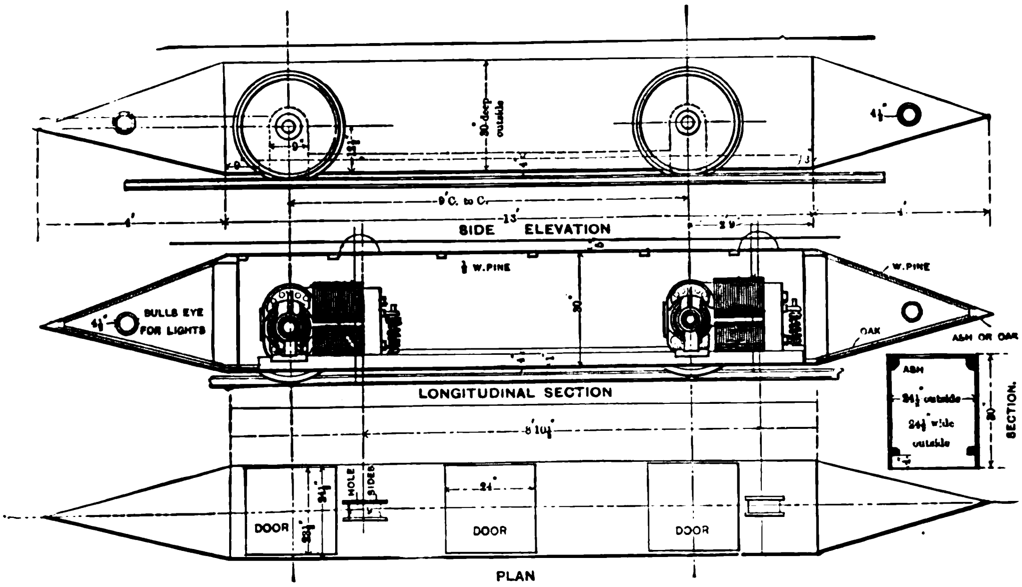

FIG. 2.—THE WEEMS ELECTRIC LOCOMOTIVE.—ORIGINAL PLAN.

The locomotive was very simple. Three axles carried 28 in. wheels; on these were hung a steel box, 16 feet long x 24 ins. high x 30 ins. wide. A slight vertical play of the box was provided for by springs, but, horizontally, the three axles were in rigid connection. On each of these axles it was designed to place a motor. The head was pyramidal; the weight of the car with three motors was about three tons. A second similar box of steel was made to be drawn by the motor-car, the two to be connected by a ball-and-socket arrangement, the interval between cars to be flanged over so that only one surface should be presented to meet atmospheric resistance. The tail was pyramidal. The second car was not in use more than once.

The track-work and cars were completed as above outlined when the matter was brought to the Sprague Electric Railway & Motor Company, with the request that they design motors of which the armatures should be placed directly on the three driving axles of the car, the construction of which was already nearly finished. It was further conditioned that the motors should do 20 h. p. of work, each, at a normal speed of about 3,000 revolutions per minute. This corresponds to a car-speed of about 250 miles per hour. Needless to say, that on so light a track, none of which was straight, and with a car weighing three tons, and with only 60 h. p. available for work, no such speed was attained. The motors were carefully designed by Mr. H. F. Parshall, of the Sprague Company, for a normal impressed E. M. F. of 500 volts, and thoroughly filled the specifications. They were to be connected in multiple across the 500-volt circuit supplied with current from a dynamo made by the Edison Machine Works. When the motors were finally mounted and ready for action, it was found almost impossible to start the car, due probably to stiff bearings, and when several trials of speed had been made, the results were disappointing.

Up to this time the electrical work had received only such engineering attention as could from time to time be given by employees of the Sprague Company, much occupied in other ways. It became evident to the Baltimore company that any satisfactory accomplishment could be had only through the continuous attention of some one having had electrical experience.

As superintendent of the Sprague Company, I had been familiar with the manufacture of the motors, and had moreover visited the plant; hence in October, 1889, it was arranged that further experiments should be under my direction. Throughout the work Mr. B. J. Dashiell, Jr., M. E., and Mr. H. F. Purdy, of the Sprague Electric Company, were of constant assistance, both in conception and execution of all that was done.

Work having been resumed, it was soon found that a given speed could be attained with less current if two motors were in service than with three, and consequently the motor on the middle axle was removed. It seems probable that, when running, this middle motor was largely occupied in skidding the wheels driven by it, since the two outer axles, on a yielding track, would doubtless support the greater part of the weight. In any case, the two motors were able to produce a greater speed than the track could stand. These machines were of the **U** type. The armature was wound with 100 sections of No. 12 B. W. G. wire, each section of two turns. This armature, with its commutator, was rigidly mounted on the axle. The pole-pieces were attached to brackets centered on the axle, the keeper was spring-supported on a cross-piece carried by the steel casing. Bearings were of phosphor-bronze and lubrication by oil from an ordinary cup. No trouble on this score was experienced. Each magnet core was wound with 120 turns of No. 4, B. W. G. wire. At 30 amperes the armature induction was about 80,000 lines per square inch. Outline of the motor is shown in Fig. 2. These motors, since wound, according to specification, for the 500 volt circuit, were originally connected in multiple arc. This connection was changed, they being placed in series, thus diminishing the potential-control, required at the station by reason of the fact that the machines were run at a speed so much below that for which they had been calculated.

---

[1] A paper read before the American Institute of Electrical Engineers, New York, February 24th, 1891, President W. A. Anthony in the chair.

[2] Pressure of other work has prevented me from carefully reviewing the calculations appearing in this paper.—O. T. C.

To supply the current, contact was made between the upper rail and brushes of sheet copper set against the rail by springs. These served their purpose well. The return circuit was through the wheels and rails, the steel casing being insulated from the axle by fibre plates and washers at joints and bolts. Rail bonds (covering joints in upper and lower rails) were used throughout; the resistance of the external circuit from the feeder junction to a point diametrically opposite was about 0.25 ohm.

The station was placed inside the circle, about 200 feet from the track. The generator was a 70 h. p. Edison machine, not compounded originally, and was driven by a 90 h. p. high-speed Ball engine. At first a wire resistance of about 12 ohms was used to lower the potential on the line, as it was not convenient to run the dynamos at less than 400 volts. Later, a whiskey barrel was filled with water, an iron plate, 8 inches square, was placed in the bottom, a similar plate was fixed to the end of an iron rod and this rod attached to the pulley, permitting easy lifting or dropping of the plate through the water. These plates being connected in the main circuit, a very serviceable liquid rheostat resulted, which, when "taken with a grain of salt," answered excellently the purpose of regulating currents which often went as high as 150 amperes.

The usual course of a run was this. Speed-observers, as many as could be had, up to five or six, were stationed around the circle, distance apart being known. Watches of these observers and of recorders who read current and potential were compared. Potential readings were taken at station and at one or two points on the line, permitting easy reduction to horse power. Mr. Dashiell, my assistant, then took the engine and I managed the dynamo. A current of from 20 to 40 amperes usually started the car. The size of the armature wires limited to about 90 amperes—45 in each machine—the current permissible for any length of time. This value was usually attained in the first half mile of run, a considerable part of the external resistance having been cut out. When the car had attained a speed of 75 to 100 miles per hour, the line potential was in the neighborhood of 450 volts, the iron plates in the barrel being in contact, having been slowly approached as the counter E. M. F. increased. The time limitation of the runs was invariably caused by failure of the track to serve its purpose. On three occasions the car left the track; once at 45 miles per hour, once at 80 miles per hour, and once, the last time, at about 115 miles per hour. Curiously enough, on the two former occasions the derailment was to the inside of the circle, superelevation being about four inches.

It was easy to tell in the station when a derailment was immi-

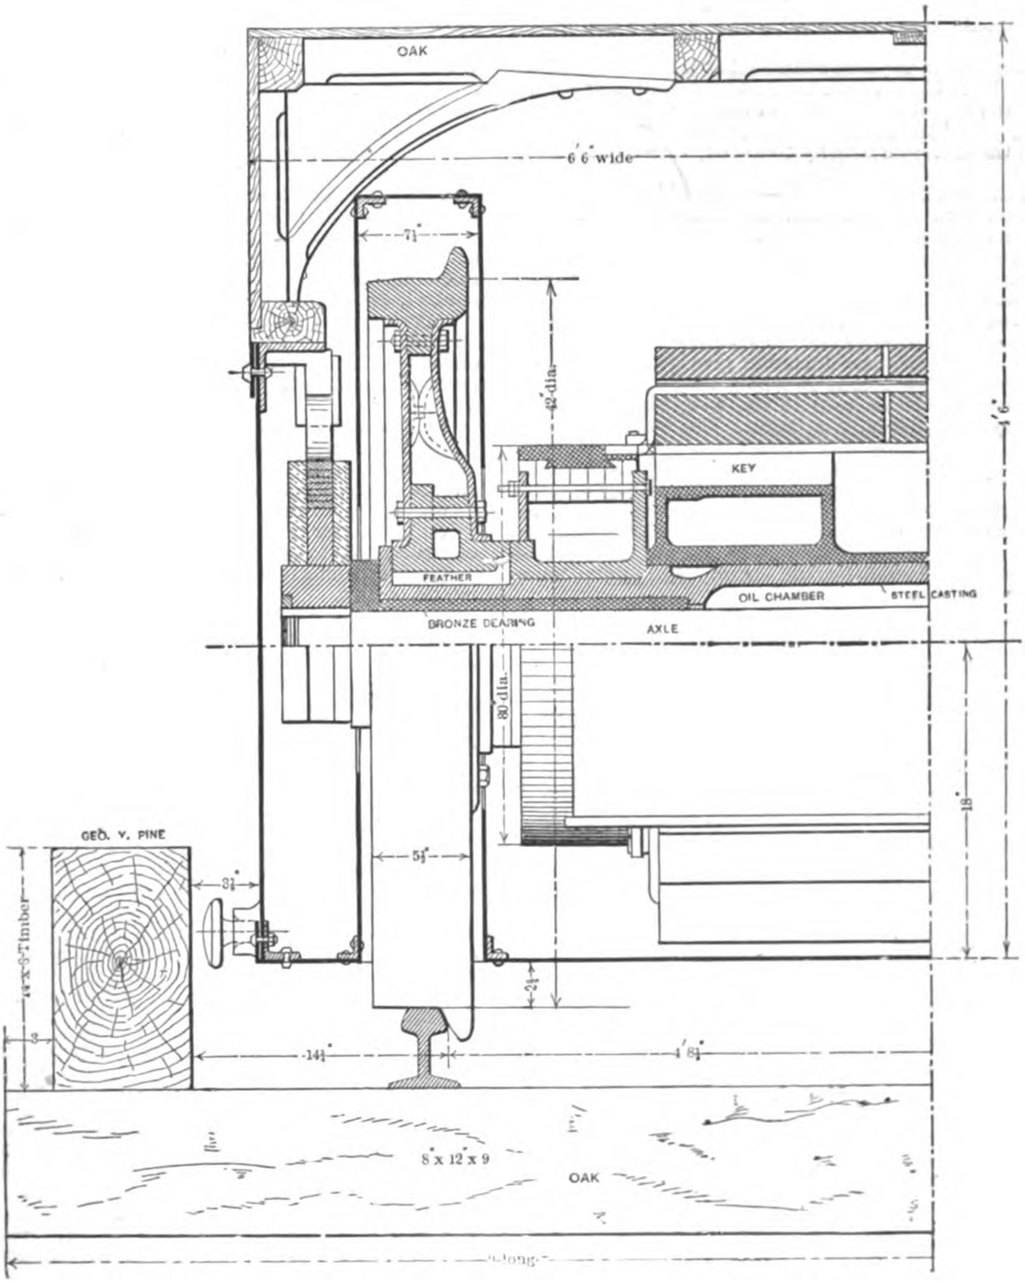

FIG. 3.—HIGH SPEED ELECTRIC LOCOMOTIVE.—HALF CROSS-SECTION.

nent, as the ammeter was most violently agitated by the make and break of the circuit caused by the particularly bad spots in the track. The agitation increased with each trip around the circle and ended in a run-off, or, after some experience had been gained, in a cessation of the trial. As the track limited the length of run in time, so also it limited the speed obtainable. Each trial—the longest being about twenty-two minutes' consecutive running—was followed by an overhauling of the track, requiring from a few hours' to a week's work by four or five men.

Could the experiments have been made on a road-bed and track, deemed even second-class according to steam railway standards of rail-weight, etc., there can be no question that without any other change, the car could have maintained for several hours a speed of 120 miles per hour. Indeed, I know of no time limitation that would have arisen save that from a limited oil supply.

The speed obtained in the first round—that is in the first 9,240 feet—varied from 30 to 75 miles per hour; this determined by the management of the rheostat. The *rate* of acceleration from point to point in going round the circle was irregular, due to the grades which, going in the direction usually followed, varied from 2.0 to 2.5 per cent.

The fact that the track—always bad—went rapidly from bad to worse during each run, made it difficult to analyze the records with a view to determining the true coefficient of traction. Moreover the coefficient for such a track, even in its best condition, would be greater than for the track that would necessarily be built for actual service. The figures obtained were of little worth as far as fixing absolute values at very high speed, but at least served to show the error of many train resistance formulæ found in the text-books. Some of these formulæ give good enough results when used for the low speeds on which they are based, but their algebraic form is such as to give rise to great error when higher speeds—say, 80 to 120 M. P. H. enter. This whole matter of train resistance has been more fully treated in a paper, "Limitations of Steam and Electricity," read by me before this Institute on May 21, 1890. (See THE ELECTRICAL ENGINEER, May 28, 1890, p. 395). The particular element of atmospheric resistance, for which special experiments were made at Laurel, was fully treated in a paper read by me before the West Point branch of the Military Service Institute, and published in London *Engineering*, issues of May 31 to June 13, 1890.

Using for atmospheric resistance, figures resulting from the experiment herein referred to, we may analyze thus:

RUN OF OCTOBER '89. FLAT HEADED CAR.

Time of 1st round, 3.8 minutes, Av. speed = 2430 F. P. M. = 28 M. P. H.
" 2d " 2.8 " " = 3300 F. P. M. = 37.4 M. P. H.
Average rate of work done by motors in 2d round = 15.0 H. P. 495,000 ft. lbs. per min.
Average horizontal effort in 2d round = 495,000 ÷ 3,300 = 150 lbs.
" " " " " for atmospheric resistance = 30 lbs.
" " " " " for acceleration (approx.) = 10 lbs.
" " " " " for other resistances = 110 lbs.
" " " " " per ton = 110 ÷ 2.4 = 46 lbs.

RUN OF NOV. 13, '89. FLAT HEAD.

Time of 1st round = 4.25 minutes. Av. speed = 2170 F. P. M. = 24.7 M. P. H.
" 2d " = 2.5 " " = 3700 F. P. M. = 42.0 M. P. H.
" 3d " = 2.5 " " = 3700 F. P. M. = 42.0 M. P. H.
Average rate of work from middle of 2d to middle of 3d round = 15.5 H. P. = 511,500 ft. lbs. per. min.
Average horizontal effort = 511,500 ÷ 3700 = 138 lbs.
" " " for atmospheric work = 36 lbs.
" " " for acceleration = 0 lbs.
" " " for other work = 102 lbs.
" " " per ton = 102 ÷ 24 = 42.5 lbs.

RUN OF NOV. 13, '89. PYRAMIDAL HEADED CAR.

Time of 1st round = 4.0 minutes. Av. speed = 2410 F. P. M. = 26.2 M. P. H.
" 2d " = 2.0 " " = 4620 F. P. M. = 52.4 M. P. H.
" 3d " = 2.25 " " = 3678 F. P. M. = 41.8 M. P. H.
" 4th " = 2.25 " " = 3678 F. P. M. = 41.8 M. P. H.
" 5th " = 2.25 " " = 3678 F. P. M. = 41.8 M. P. H.
" 6th " = 2.25 " " = 3678 F. P. M. = 41.8 M. P. H.
Average rate of work in last four rounds = 16.0 H. P. = 528,000 ft. lbs.
" horizontal effort = 528,000 ÷ 3678 = 144 lbs.
" " " for atmospheric work = 24 lbs.
" " " for acceleration = 0 lbs.
" " " for other work = 120 lbs.
" " " per ton = 120 ÷ 2.4 = 50 lbs.

[illegible]

[illegible]

and we have:

Average speed = 8,800 F. P. M. = 100 M. P. H.
" horizontal effort = 44 x 33,000 ÷ 8,800 = 165 lbs.
" " " for atmospheric work = 48 lbs.
" " " for other work = 117 lbs.
" " " per ton = 117 ÷ 2.4 = 48 lbs.

Highest speed attained this run = 110 to 120 M. P. H. Track better than in last run, but car was derailed at maximum speed.

These values, 46.0, 42.5, 50.0, 58.7 and 48.0 lbs., should be corrected for curvature, making them, 30.7, 28.4, 33.4, 39.1, and 32 lbs., respectively. Other and lower values were obtained when the track, as at first, was in better condition. But these earlier runs were not recorded in exact figures. The rails were in all cases rusty.

The speed at which this derailment took place could not be absolutely determined, since the car left the track at some distance from the last two observers, whose time records gave the speed attained between the points of observation. It was clear, however, that final speed was between 110 and 120 miles per hour. A length of 1,000 ft. of track was injured, about 300 ft. of the upper framework wrecked, and the car itself was landed about 30 ft. from the track, having finally jumped the guard rails while going over a fill 4 or 5 ft. high. It seemed clear that the Laurel plant had passed its days of usefulness. Nothing further of value could be done without practical rebuilding. It was then time to make new plans, and this work was at once begun by Mr. Dashiell and myself. At the outset I felt that—if for no other than commercial reasons—we should plan for the carrying of passengers as well as parcels. This meant an increase in the size of cars and a change from an attempt at automatic control, to control by human intelligence on the locomotive.

For purposes of demonstration I proposed to the company that they should build a track about four miles (not less) in circumference and should run thereon a train of two or three cars drawn by one locomotive. Calculations were based on the following data:

(1) A speed 150 miles per hour on a level was to be aimed at.

(2) Cross-section of car should be a minimum, consistent with the seating of passengers. This was taken at 6 ft. by 5 ft. 30 sq. ft. (crowning higher along middle of car).

(3) Gauge of track should be standard—4' 8.5".

(4) Character of track should be simply the best that art could contrive, rails to be from 65 to 90 lbs.

(5) Electromotive-force should be as high as the art of insulation would permit.

(6) Whatever might be the number of cars in a train, all were to be so connected as to present a continuous exterior, thus presenting only one cross-section to the atmosphere.

(7) Atmospheric resistance at 150 miles per hour would be taken at 15 lbs. per square foot of cross-section, a wedge or parabolic locomotive head being used. This value is 50 per cent. in excess of that indicated by our experiments.

(8) Traction coefficient, exclusive of air resistance, would be taken at 150 miles per hour, to be 35 lbs. per ton—this for reasons set forth in previous papers.

From the two resistance coefficients just given, it followed that for every square foot of cross-section, regardless of weight, 6 horse power would be required, and for every ton of weight, regardless of cross-section, 19 horse power must be supplied.

For a locomotive of about 600 horse power having 30 ft. cross-section, the dead weight was calculated to be about 18 tons. Steel cars of equal cross-section were designed, weighing, empty, about 5 tons, with carrying capacity of about 5 tons.

The important question as to power required could then be thus tabulated:

	150 M. P. H.	120 M. P. H.
Locomotive alone	300 H. P.	228 H. P.
Locomotive and one car loaded	400 "	300 "
Locomotive and two cars loaded	500 "	446 "
Locomotive and three cars loaded	600 "	525 "

To perform the work here indicated two motors were provided, one armature directly on each of the two axles of the locomotive car. These motors, outlined in Figs. 3, 4 and 5 were of the Manchester type. They were supposed to be at first connected in multiple arc across a [illegible] volt circuit, each taking about 130 to 150 amperes and delivering about 250 to 300 horse power. Should it be desired to experiment with higher line potential, the motors in series would permit [illegible] volts to be easily tried. The armatures of the Gramme type are [illegible] in. outside, 23 in. inside diameter. The armature conductors were to be of about 40,000 circular mils cross-section, or [illegible] to 300 c. m. per ampere. Many successful machines, designed to work indoors, go as low as this figure, and since the dissipation of heat must in such case proceed more slowly than in the case here considered, the figure seemed very safe. Moreover, it was intended to introduce a blast of air from the car front which should continuously flow through the open [illegible] of the armature ([illegible] type). How far the rate of dissipation would be effected by such means can not now be known. [illegible] experiments of Mr. Kennelly) goes to show that the [illegible] capacity would be much increased.

The cross-section of [illegible] in the armature was 3.5 x 40 = 140 square inches gross, [illegible] 15 per cent. for paper insulation [illegible] per cent. for commutator slots [illegible] square inches net. Through this armature it was desired to force 22,000,000 lines (C. G. S. units) or 100,000 per square inch = 15,000 per square centimetre.

The hysteresis loss in such armature revolving at 1,200 R. P. M. (equivalent with 42 inch wheel to 150 M. P. H) was calculated to be about 3,000 watts—following the curve published by Esson. The $C^2 R$ loss ($C = 135$ amperes, $R = 0.26$ ohm when $T = 75°$ C) = 4,740 watts,—or about 8,000 watts for the two losses. I found it difficult to obtain such coefficient as would give reliable values for loss due to Foucault currents. With very thin plates it would not be large. From what precedes, it followed that the number of armature conductors should be 340. These were divided into 170 sections, wound in one layer, each conductor to lie in a slot; both slot and conductor were planned to be rectangular, or nearly so, with the reservation that experience in manufacturing would soon show the proper detail.

The magnets have a cross-section of 164 square inches, through which 14,300,000 lines of force must pass, the increase from the number in the armature being determined by a leakage coefficient 1.3.

The magnet coils of the two armatures were calculated to be in series with each other, but in shunt with respect to the two armatures. This variation from present street car practice I thought to be justified by the following considerations: First, no system of commutation could obviate the need of a considerable external resistance, which then could be easily made sufficient, within itself, for speed control; second, the maximum torque for a given armature current is always desirable and can be best obtained by permanent saturation; third, this constant and maximum magnetization would tend to diminish sparking—an evil to be specially avoided in long distance work, involving continuous runs of several hours.

While it was thus intended to use shunt coils at first, I felt that a little experience would soon positively demonstrate that the advantage lay with this or the series winding.

The commutator, Fig. 3, was designed to be 23 inches in diameter, which would of course give rise to a very high speed relative to the brushes. I believe it better to face the mechanical trouble that might be connected with great circumferential speed, rather than to diminish the diameter by decrease of sections, since this in turn might produce sparking.

Without going into the mechanical details of the commutator, I may add that a single bar could be taken out or replaced, without removal from the shaft.

The rheostat for the armature circuit was designed to be of iron wire, with the expectation however of experimenting also with liquid or carbon resistance. The resistance and heat capacity of this main line rheostat were determined with reference, first, to current necessary for starting, second, to currents needed for maintaining low speeds. The starting current on practically level track was calculated to be from 300 to 400 amperes, the load being 80,000 lbs. (or locomotive and three loaded cars). For continuous running at 30 miles per hour, a current of 40 amperes would be required, the counter E. M. F. of each of the 1,500-volt motors being, at this speed, only 320 volts. The line-potential being 3,000 volts, it would be necessary to have in the armature circuit an external resistance of 59.0 ohms $= \frac{3000-640}{40}$. The wires were calculated to stand 40 amperes continuously, and the various sections were proportioned to stand the various currents for such time as would serve to bring the train up to speed. It was, of course, known that a considerable reduction in the size of resistance box could be effected by winding the motors for the regular line potential, thus normally working them in arc, but putting the armatures in series where a great reduction in speed might be required.

A small rheostat and a condenser were designed to be placed in the circuit of the magnet coils, and a rheostat also in the lamp circuit, these resistances giving delicate control.

The problem of retardation for a mass of say 40 tons running at 150 miles per hour is a serious one. The Galton and Westinghouse tests indicate a very low value for the coefficient of friction between brake-shoe and wheel, at high speeds; they report it in some cases at 60 M. P. H. as low as 0.04. As, however, it rapidly increases at lower speeds, an average of 0.1 may be taken. The total retarding effort, *i. e.*, brake resistance and track and atmospheric resistance, must be kept below that which will just produce sliding of the wheels, and the coefficient of sliding may be taken on an average at 0.08 of the weight of the wheels. If then we represent by P the maximum allowable brake pressure on the wheels, by R resistances other than brake friction, and by W the weight on braked wheels, we may write the following inequality: $0.1 P + R < 0.08 W$.

The value of P should be determined as that which, with a small margin, will satisfy this condition of inequality.

Following this calculation, it was found that a brake-pressure of about 5,000 lbs. should be applied to each wheel. This was designed to be produced by magnetic brakes similar to those used by Mr. Daft on the New York Elevated Railway. The form and approximate dimension of those brakes are shown in Fig. 4.

A mass of 80,000 lbs. moving at 150 miles per hour represents 64,000,000 foot-pounds of energy. Average resistance due to brakes = 0.1 x 60,000 = 6,000 lbs. Average resistance from track and atmosphere for average speed of 75 miles = 400 lbs.

In addition, the motors may be required to generate a current which shall be wasted over the rheostat. Since the field-circuit in the case of shunt-motors, is independent, magnetization may remain constant, and average E. M. F. of 1,500-volt motors (*i. e.*, motors generating 1,500 volts E. M. F. at 1,100 R. P. M. or, with 42″ wheels, at 150 E. M. F.) would be, while the train was coming to rest, 750 volts. Make the external resistance such, that the two armatures being in series, an average current of 200 amperes shall flow. Then, average dynamo resistance, in lbs. = 2,000. Total retarding effort = 6,000 + 400 + 2,000 = 8,400 lbs. Dividing 64,000,000 by this last quantity, we have 7,620 ft. as the length of run to come to a stop, and the time of stopping about 100 seconds.

For the mechanical construction of the locomotive, two plans were contemplated. One has a 12-foot rigid wheel base and no pilot wheels; the other has a 7-foot wheel base for the drivers and a pony-axle in front, free to move laterally over a certain distance, dragging the drivers in the same direction. This is the general principle of pilot-wheels, so largely used on high-speed engines. This second arrangement, Fig. 5, is preferred. In it nearly all the weight goes on the drivers. In this particular case, total weight of locomotive is about 18 tons, each motor being six tons. Of the total, 15 tons rest on the drivers. If then the adhesion-coefficient, while running, be taken at only 0.1, a circumferential effort of 3,000 lbs. may be exerted without slipping the wheels. This is safe, since if 600 h. p. of work be required at 150 miles per hour (= 13200 f. p. m.), the horizontal effort $= \frac{600 \times 33{,}000}{13{,}200} = 1{,}500$ lbs. For starting the load, adhesion-coefficient may be taken at 25, giving 7,500 lbs. possible pull, this being much in excess of the value required.

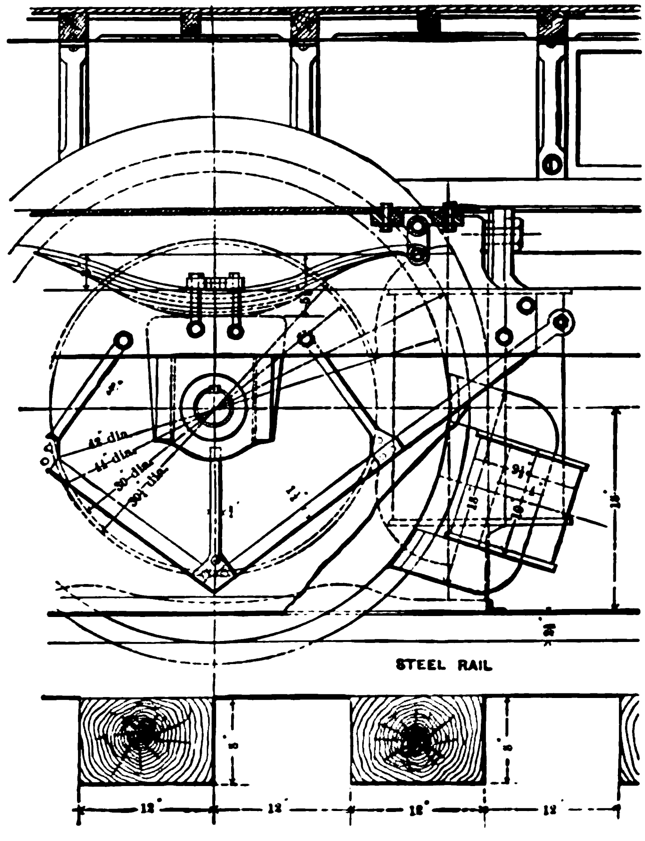

FIG. 4.—HIGH SPEED ELECTRIC LOCOMOTIVE.—BRAKE MECHANISM.

The locomotive construction is such as to put the entire weight of the armature directly on the axle. In designing this, I did not overlook the fact that the armature must thus be subjected to much jarring. But I believe the difficulty should be met by excellent mechanical construction, rather than that spring movement should in any way be attempted. For mechanism that shall succeed in high speed, long-time service, simplicity is a requirement of the first order. Indeed, generally, in this work of connecting an electrical motor to any vehicle, I have long felt that he who is over-ingenious in contriving many parts and fine adjustments, may not be over-successful.

The weight of the magnets and pole-pieces goes also directly on the axles, save for the intervention of rubber plates having a maximum play of 1-16 of an inch. By the use of motors of the "**U**" type, part of the weight might be spring-supported, but on the other hand it is not as easy, with that type as with the Manchester, to obtain a perfectly sparkless motor. Moreover the weight going dead on the axles in the case considered, is not greatly in excess of that due to 8-foot drivers and other attachments of large steam locomotives. Further the need of any spring movement decreases with increasing perfection of track-work, as, in an ideally perfect track, car-springs would not, save on curves come into play.

In the first design of locomotive cars, the operator is to sit between the two motors, where also would be placed the controlling devices. In the second design, the operator would be placed over the pony-axle, the devices being chiefly in the cylindrical or parabolic head.

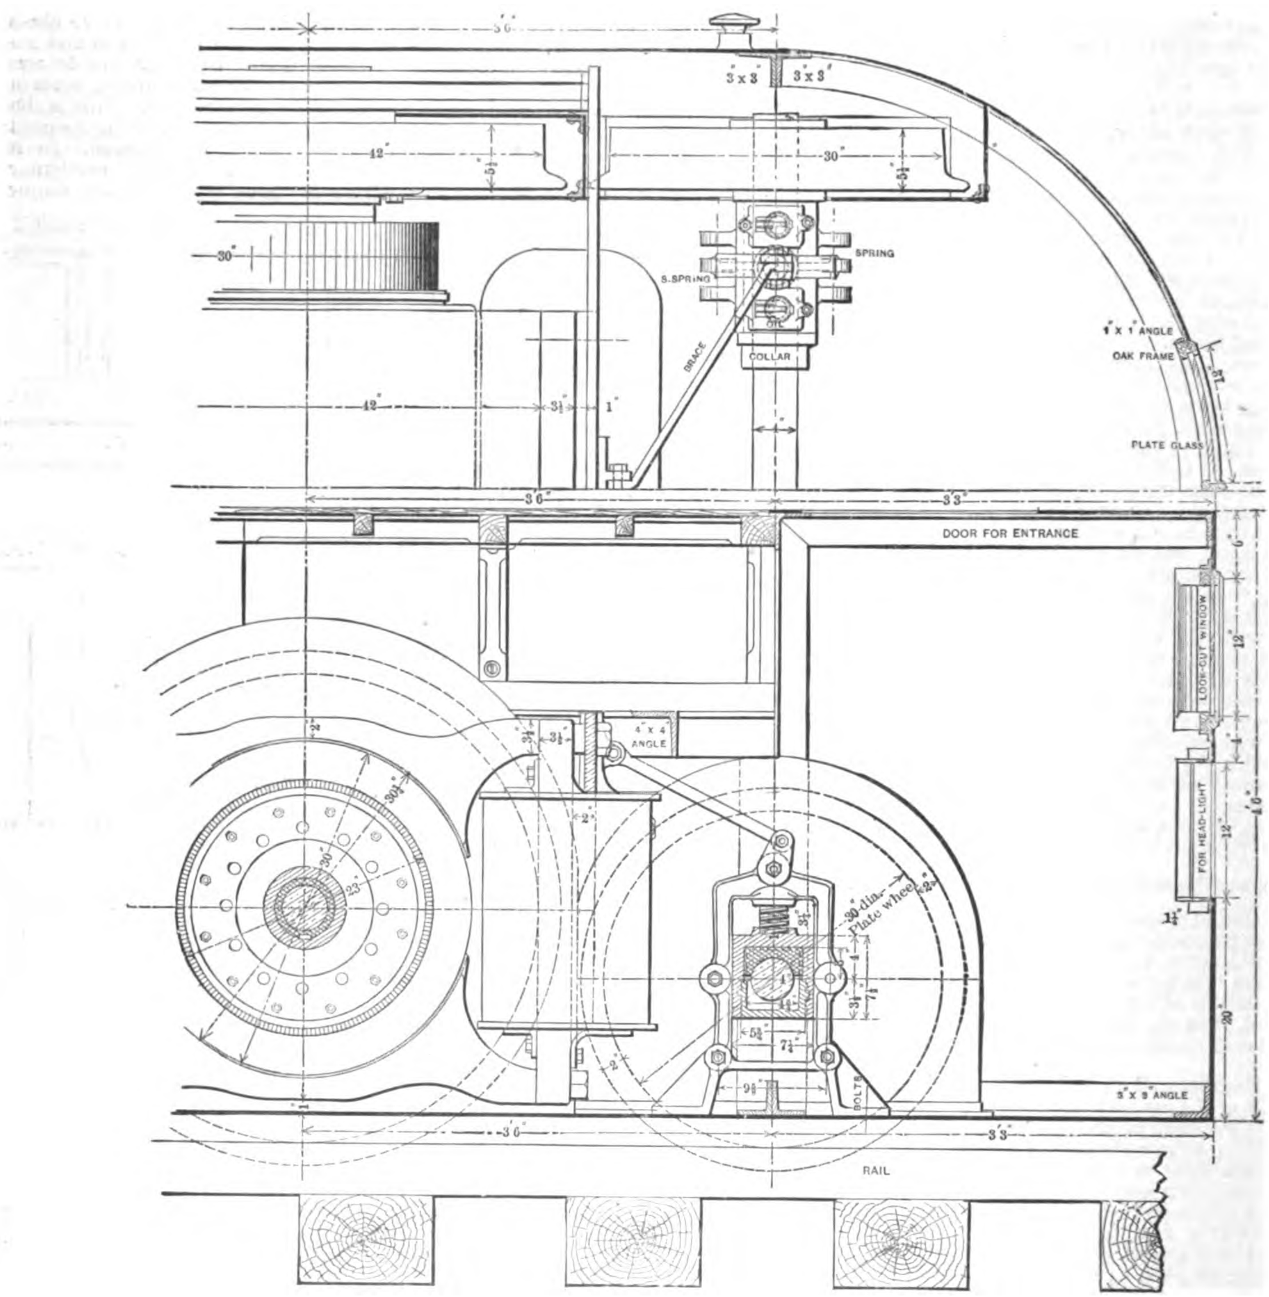

Fig. 5.—High Speed Electric Locomotive.—End of Car, Elevation and Plan.

Detailed drawings of freight and passenger cars were completed, but need not here be referred to.

As to the supply of current, it is proposed to use the double metallic system. This departure from the ground return, now so commonly employed in street railway work, seems justified by the following considerations:

1st. For a given voltage it diminishes the cost of insulation, per se.

2d. It diminishes the danger of accident within the motors.

3d. It diminishes danger of accident to workmen.

4th. By being thus more easily handled, it is probable that a higher voltage will be found practicable than with the ground return; hence, in fact, even first cost might not be greater.

As designed, the conductors will be placed in an inverted wooden trough, attached to posts placed at 12 feet intervals on each side of the track. The trough to be about 5.5 feet above the ground. The conductors for each side of the circuit to be two—one insulated and continuous; the other a bare, flat strip, broken into sections, these being normally out of circuit; the locomotive trolley-arm operating a switch which shall throw out the rear section, and throw into circuit the section ahead. Such a switch was designed in detail.

As to what the line voltage should be, progress in the art of insulation can alone determine. It would, of course, not be necessary, on a roadway for long-distance travel, to consider the death-producing voltage as a limitation.

In the important matter of limiting curvatures, calculations were made in the ordinary way, using the particular values for weight and height of centre of gravity. A safe speed was then tabulated as that which is just one-half the speed that causes the resultant of weight and centrifugal force to pass through the outer rail of a curve. The beneficial effect of superelevation, neglected in the calculation, would, of course, practically increase the factor of safety.

The following table resulted from the method described:

Radius in feet.	Safe speed, by rule above, in miles per hour.
1.000	71
2.000	98
3.000	120
4.000	140
5.000	158
6.000	172
7.000	187
8.000	198

Of course, naught save practical trial could determine whether the assumed factor of safety, which is quite large enough at present speeds, would, in fact, be right for the higher speeds aimed at.

COMMERCIAL ASPECTS.

Copper calculations were made, based on a station potential of 3.000, and also of 6,000 volts, stations being 50 miles apart (thus supplying current 25 miles on each side) and on a service requiring one train on each 25 mile section, the drop on the line being 33% of station potential. Then for a line of 1,000 miles, as from New York to Chicago, with copper at 15 cents per lb., and for 3,000 volts initial:

	Per mile.
Cost of conducting system, including frame work - - =	$ 7,000 00
" station per mile, including steam - - - - - =	3,000 00
" double track, including depots, etc., - - - =	55,000 00
" train equipment, 3 cars each, 50 trains and engines =	1,000 00
Total per mile - - - - - - - -	$66,000 00

In this, the cost of track construction is based on road-bed figures reported for the Erie Railway Co. To arrive at operating expenses, suppose 20 trains each way each day, and a schedule of 125 miles per hour, *i. e.*, 8 hours for the trip. Suppose a station development of 800 h. p. per train on the line, or 64,000 h. p. hours per trip. In stations of large capacity working under the supposed conditions, the cost of one h. p. hour = 0.90 cent (see tables in previous paper "Limitations of Steam and Electricity") or per trip, for power a cost of $57.60. For train men, suppose two men on each train, and one per train in reserve, and suppose $3.00 per man per trip of 8 hours, then, cost per train trip = 3 × 3 = $9.00. Interest charged per train trip =

$$\$66,000,000 \times 0.05 \div 365 \times 40 = \$225.42.$$

For maintenance of way (see Wellington's Statistics), take $1,000 per mile of double track per annum, or per day for supposed line, $2,700.00; or per train trip, 2,700 ÷ 40 = $67.50. For general expense of operating company, suppose $1,000.00 per day—or per train trip $25.00. For wear and tear, oil, etc., on train itself, take $10.00 per trip. Then total = 56.60 + 9.00 + 225.42 + 67.50 + 25.00 + 10.00 = $394.42.

For receipts:

Suppose average train be of two cars (such as designed) having each a capacity of about 10,000 lbs. freight (considered such, as express and mail matter), or of say 15 passengers. Suppose average train load of freight, 15,000 lbs., of passengers, 20. Take freight at 33 cents per cwt., passengers at $25.00. The income per trip in either case—$500.00, showing profits, over fixed charges, of say $100.00 per trip, or $4,000.00 per day. The total daily load of freight, each way, required to justify the service above treated, is 300,000 lbs., or if 200 through passengers be carried (*i. e.* ten trains for passengers each way each day), then only 150,000 lbs. of freight. The *present* movement between New York and Chicago, in mail and express, is not far from this figure. A five-hundred mile line, connecting Boston, New York, Philadelphia, Baltimore and Washington, would be even more profitable. It is to be remembered also that a service of *small* trains is contemplated, making fixed charges relatively very large. Much larger trains could be, and I think *will be*, run at the speeds here considered, but I have supposed that the smaller effort would precede the larger. It is further to be noted that the use of 6,000 volts potential, and the extension of some existing roadway instead of the building of a new one, would diminish first cost. As grade-crossings would be out of the question, and as cities would require to be entered above or below the surface (country roads to be carried over on bridges), it is perhaps best to consider only the larger figure already used.

To demonstrate all or nearly all that has been outlined in this paper will cost about $300,000, covering the construction and operation for a reasonable time, of the four-mile circular line proposed above. Last year the Baltimore company met unexpected difficulty in efforts to raise the needed money; their operations were suspended and my connection with them ceased just at the time when plans were completed—even to working drawings. I have been much pleased to learn, within the last few days, that far from being discouraged, they are now confidently hoping that they may push on, in the near future, the great work to which they have laid their hands.

Unfamiliar as is the project, you will perhaps be the more ready to share the confidence of its promoters, on hearing the words from Prof. Henry A. Rowland and Dr. Louis Duncan, of Johns Hopkins, to whom were submitted, last spring, full details of the plans partially described in this paper, after reviewing the figures for power required. They say:

"We believe from the data obtained that the values given are not too low, and that the horse power which Mr. Crosby calculates is *not less than the amount required*. While we have investigated carefully and considered all the data obtainable, yet the existing experiments are not sufficient to accurately fix a limit to the train resistance. *We believe, however, that the value assumed by Mr. Crosby is safe.*"

"The motors, the calculations and drawings for which are in the appended statement, will develop the horse power for which they are designed, namely, 500 horse power. We point out some modifications which will be beneficial. *We believe that they will drive the train* (locomotive and two cars, O. T. C.) *at the required speed.*" (Italics here and elsewhere are mine; speed then considered, 120 miles on a level. O. T. C.)

"The possibility of a train being derailed by an obstruction on the track increases with the speed. At speeds up to 90 miles, however, there seems no increase in the number of derailments. In the case in question, the centre of gravity of the cars is very low, and *it would be difficult to derail them on straight parts of the track*. The radius of the curves should of course be great, but not so great as would be required for an ordinary train going at these high speeds. *The question of safety is*, however, *almost wholly a question of track construction.* Considering the form of the proposed train, its comparatively light weight, making a less demand on the track, it is certain that, with a carefully constructed road, it could attain, with safety, speeds which would be impossible with trains as at present constructed. As these latter have several times made 86 miles, and often made 80 miles, *it would seem that a speed of* 120 *miles or even more, with the electric cars, would not be outside the limits of safety.*"

"The plan for supplying current to the motors is feasible."

"The design of the motors is discussed in the detailed report. It is generally good."

"Should it be demonstrated by an actual test that passenger trains can be run safely and economically at a speed over 100 miles per hour from here to Chicago, the financial aspects of the case would certainly be improved. *We are of the opinion that the chances are in favor of this being accomplished by the present scheme.*"

These words, though guarded and accompanied by criticism of the detail, are yet a substantial approval of what was submitted. To me, they were very encouraging.

THE TELEPHONIC REPRODUCTION OF SPEECH.[1]

BY E. MERCADIER.

THE principal object of the telephone is the reproduction of speech at a distance with all its component elements; the articulations with their inflections, the vowels and diphthongs with their characteristic accents, timbre with all its delicacy, and the whole reproduction with sufficient intensity. But the transformations of energy, which go to make up telephonic effects, tend to injuriously affect the human voice.

An alteration of timbre, consisting of a disagreeable snuffling, which distorts words, is due to the fundamental note and harmonics of the diaphragm being superimposed upon those of the voice, without becoming confounded with them; and producing a disturbance of the electric waves, of the movements of the diaphragm molecules, and, therefore, of the sound waves which reach the ear. If my theory be correct, it is not necessary in order to correct this alteration of timbre, to take a diaphragm the fundamental note of which is superior to the limit of the sounds emitted in articulate speech, that is to say, one whose fundamental note is somewhere about ut_4 for men and ut_5 for women. Then the human voice would not tend to produce the fundamental note and harmonics of the diaphragm, which would no longer coincide with the tones of the human voice. Moreover, in order to produce them it would be necessary (owing to the stiffness of the diaphragm) to employ a mechanical force greater than that which the human voice is capable of exerting when speaking. This has been verified by experiment. I will only cite two extreme cases. A diaphragm of 100mm. diameter and 1mm. thick, or one 30mm. diameter and .1mm. thick. Both satisfy the condition mentioned above, and, fixed to appropriate telephones, neither of them produces a sensible alteration in the timbre of the voice.

The alteration of articulations and vowels consists, on the one hand, of the exaggerated predominance of certain consonants, vowels and syllables, *p, b, r, k, a, o, un, on, ent;* and in the marked weakening of *l, s, c, z, i, e* and *u*. The consequence is, that it is frequently very difficult to understand the words distorted in this way. The alteration is due, in large measure, to the shape and aperture of the buccal cavity, which are different in the pronunciation of the various articulations and vowels mentioned above, and to the resulting energy of the sound waves being much weaker in the second case, than in the first. From this point of view this distortion would seem inevitable, but it is also due in some degree to the correlative production of the harmonics of the diaphragm. In fact, while seeking to remedy this defect, I found that it was markedly diminished by precisely the same method as indicated above, employed to suppress the alteration of timbre, that is to say, by suitably proportioning the thickness and diameter of the diaphragm so that its fundamental note shall be very sharp.

---

[1] *Comptes Rendus.*

The line joining the transmitter to the receiver also plays a certain part in this connection, which I hope to examine later on.

The third difficulty is the production of two parasitic resonances. The first of these is only noticeable to trained ears, and consists of a metallic crackling, apparently due to a kind of friction along the radii of the diaphragms caused by a change in the direction of the lines of force. This disappears in a diaphragm of high fundamental note. The other effect is the resonance due to the mass of air in the telephone box itself, and may be eliminated by decreasing the air space, by filling the box with felt. At the same time that we obtain clearness in the reproduction of speech, we satisfy the conditions necessary to obtain sufficient loudness, a very fortunate circumstance, since the two desiderata of clearness and loudness are equally indispensable. This fact thus permits us to approximate perfection in an instrument, as delicate as it is marvelous.

THE TELEPHONIC SITUATION IN ENGLAND.

A LARGE number of the National Telephone Company's shareholders met specially a few days ago, writes our London correspondent, to consider the position of the company, now that the first master patent had expired. Many were disposed to look upon the future with misgiving when the right of monopoly was taken away, but before the crowded assembly dispersed it had caught the enthusiastic spirit of the president. The statement as to the business done and the proposed new capital, impressed shareholders favorably as to the future progress. The accounts were so good that they eclipsed all former records of profits. The chairman then spoke of the lowering of rates in the country from £15 to £10, and thought the large influx of new subscribers would more than compensate for the loss incurred. In proof of this, it was stated that during the last half year 1.940 were wired up, giving an average of 74 per week; since the decrease in rates 651 new customers were wired in the first three weeks of this year.

No one can doubt the strong position held by this concern, for it starts in the competition with the advantage of having connections all over England, and no less than 244 towns linked together. It would necessitate an enormous outlay before any other scheme could approach this state, and were the company only likely to be disturbed by private individuals, it would suffer little. It is not, however, new enterprise which will cause a panic, it is the taking over by the post-office of the telephones, a fact which seems to be altogether ignored by the officials of the National Company. For, although the postmaster-general cannot stir in the matter for five years, I imagine, in the event of the company applying to Parliament for statutory powers, which is spoken about, the post-office will make its power felt.

THE ELMORE COPPER DEPOSITING PROCESS.

THE Elmore Copper Company issued invitations recently to members of the press to view the working of the special process at Leeds. In response a large number journeyed down to Yorkshire, including the London correspondent of THE ELECTRICAL ENGINEER.

The works consist of a melting shed where rough Chili bars are melted and converted into convenient form for introduction into the depositing tanks; dynamo room, where are three Mather & Platt's dynamos and Williams and Robinson's engines; depositing tanks; machine hop, where the process of removing the copper tubes from the mandrels is operated; and the testing room.

The following is a rough sketch of the process: Rough Chili bars, containing ninety-seven per cent. of copper, are melted in a furnace and then ladled out and dropped into a tank of water, the copper being afterwards taken out in the form of large granules technically termed "shot copper." These are taken into the depositing room and packed on perforated copper plates at the bottom of each of the sixty tanks to the depth of some inches, so forming the anode. The tanks or baths are about twelve feet and twenty inches, by three feet, six inches, and contain one, two, or three iron mandrels, ten feet, six inches long, and varying from four to eighteen inches in diameter. The tanks are connected in series; about forty were working during the visit. The mandrels revolve in the tanks by means of chain gearing connected at one end of each bath, each set being actuated by pulleys attached to a long line of countershafting running the length of the tanks. It will be seen by this that the deposition on the mandrel takes place from underneath and the circuit is completed by brushes similar to those used for dynamos rubbing on one end of each mandrel. The burnisher, an agate rubbing over about one-half an inch length of surface, moves slowly from end to end of the mandrel, each point of copper surface thus receiving a rubbing under slight pressure about every forty minutes. The current used was said tobe 750 amperes, and the E. M. F. at each tank terminal about .9 volt. Each mandrel has to be first coated with a film of copper in a cyanide bath before it is introduced into the tank, for the purpose of forming a tube upon it, and after the proper thickness has been obtained there is the process of removing the tube, and recoppering the mandrel. The removal is effected by letting the mandrel with its copper deposit revolve, while a machine having a couple of rollers running at right angles to the tube above and beneath it, passes slowly along its length and loosens the copper from the iron; it is then taken to another machine and the tube pulled off the mandrel.

The single plant in operation is stated to be capable of yielding a deposit of some five tons per week of 168 hours. A specimen of copper cut circumferentially gave an elongation of twenty-one per cent., the breaking strain representing twenty-one tons on the square inch.

Literature.

Dynamos and Electric Motors; All About Them. By Edward Trevert, 1891. *Bubier Publishing Company,* Lynn, Mass. Flexible cover, 5x7 inches, 96 pages. Price, 50 cents.

In this little work the author has attempted to give the reader a practical idea of what modern dynamo electric machinery consists of, and has adopted the very excellent plan of carrying this out by means of a detailed description of the manner in which dynamos and motors are constructed, giving full detail drawings and dimensions so that the reader is thereby enabled to construct such a machine for himself. This is followed by an explanation of the methods of construction of an electric battery for running electric motors. The little work contains many practical hints and will no doubt interest a large class, among those who take pleasure in constructing their own experimental apparatus. Mr. Trevert is doing good work in an unpretentious but effective manner.

Bibliotheca Polytechnica; Directory of Technical Literature. By FRITZ VON SZCZEPANSKI. New York, 1890. The International News Co.

THIS is a classified catalogue of books, annuals and journals, published in America, England, France and Germany, relating to legislation, hygiene, and daily life. As it was originally published in German, the alphabetical classification is arranged with reference to that language; so that an English or French reader is confronted with some difficulties. Although the book has evidently been compiled with care, there are many omissions, and the work has, we fear, fallen short of the excellent intention of the compiler.

May's Popular Instructor, for the Management of Electric Lighting Plants. By OSCAR MAY, PH.D.; Frankfort o. M. Shirmer and Mahlau; London, *The Electrician.*

THIS little book is intended to supply the owner of an electric lighting plant with a set of printed instructions, enabling him to check his engineer; and also to assist the engineer in the performance of his duties. The subject is treated so popularly that it may be fully grasped by any one not possessing technical knowledge. In addition to the instructions, which are very complete, there are extracts from the Phœnix Fire Office rules.

Letters to the Editor.

THE ADOLESCENCE OF ELECTRICITY.

Apropos of Prof. Sweet's communication giving a remarkable quotation from some old book about electricity and your editorial remark thereon, I may recall that in a paper which I read in 1884 before the Conference of Electricians at Philadelphia, a quotation was given from a book entitled "An Essay on Electricity," by George Adams, published in London, 1792, which reads:—"As electricity is in its infancy when considered as a science, its definitions and axioms cannot be stated with geometric accuracy."

In this, therefore, you will see not only expressed the hopeful spirit which is manifested concerning the science at the present day, but also expressed in the same words that the electrical Saul among the prophets still uses when he feels moved to say something about it. It was all right then, but it is effete now; it may still be "youth," certainly not "infancy."

THOS. D. LOCKWOOD.

LONDON.

Interesting Installation.—Electricity in the Holy Land.—Lighting of Durham Cathedral.—Electric Lighting of the City of London.

AN interesting installation has been erected at a saw mill at Neuss by the Deutsche Elektricitat Gesells. of Aix-la-Chapelle. The motor is one of 20 h. p., which serves to haul logs of wood up to the works from the neighboring Erft canal; the dynamo supplying current to the motor is also used for lighting the premises.

A decided sensation has been caused in Jerusalem by the introduction of the electric light into a flour mill, nigh unto Damascus Gate. It need hardly be said that the Arabs and Jews are much puzzled to account for a light in a lamp in which there is no oil, and up to the present time while gazing with wonder have been keeping at a respectful distance.

I mentioned in a previous communication the probability of using electricity for lighting Durham Cathedral. This project has come to a head, and successful experiments have been carried out to determine the exact lighting power required.

The first practical costructive step towards lighting the city of London by means of electricity was taken a few days ago, when the lord mayor placed in position the first stone of the main junction box for the electric conductors at the top of Wallbrook, close under the shadow of the western walls of the Mansion House. The partial lighting of the city by electricity took place some ten years since, but the imperfections which developed in the earlier systems of illumination operated to prevent any further steps being then taken to extend it, although a sum of £12,000 was spent. About eight years since negotiations were set on foot by the commissioners of sewers with a view to introduce the electric light in its most improved form into the city on a thoroughly practical and commercial basis. The result has been the division of the City into three sections. The eastern division comprises the whole of the city east of the Mansion House, the central division is that between the Mansion House and St. Paul's Cathedral. The third and western division comprises the remainder of the City west of the Mansion House as far as Temple Bar. The central and western divisions have been handed over under contract to the Brush Electrical Engineering Company; the eastern division will be lighted also under contract by the Laing, Wharton & Down Construction Syndicate. The contracts made by the commissioners of sewers provide for the lighting of the whole of the streets of the City of London, partly by arc lamps and partly by glow lamps. The contractors for the central and eastern divisions have obtained powers for supply of electricity to private consumers; and in the western division similar powers are being applied for. The contractors will light every street, lane, court and alley and will obtain what practically amounts to a monopoly in private supply.

According to the scheme, the streets will be lighted in all by 400 arc lamps of 2,000 nominal candle power and 1,000 glow lamps of varying candle power. It is estimated that the cost to the City when the work is fully completed will not very much exceed £20,000 per annum; of this sum the commissioners anticipate that about twenty times the illuminating power at present obtained from gas will be secured. The contracts require that the works for public lighting shall be commenced before the 19th inst., and this ceremony consisted in starting the underground works. This commencement comprises the main junction box, which will be employed for connecting the mains of the two contractors. The object here is to make the systems inter-dependent, so that in the event of a serious breakdown occurring at either of the generating stations, the electric current will be obtainable from the other station.

The sites of the stations have been fixed on the side of the Thames, having a combined capacity of 1,200 2,000 c. p. arc lamps and 120,000 incandescent lamps of 60 watts.

LONDON, Feb. 4, '91.

Electric Lighting in the City.—The Guernsey Electric Railway.

SINCE my last communication the Brush Company and Laing, Wharton & Down Syndicate have agreed to transfer to a new company the contracts for lighting the city of London by electricity. Although obscurity is a characteristic of legal documents, the agreements made between the companies are remarkable for opacity. They are so skillfully or unskillfully worded, so intentionally vague, that none but those actually engaged in the transaction could tell with exactitude the precise gain of the vendors. It is true sums of money, presumably large, are supposed to change hands, and that the purchasers acquire contracts, provisional orders, central stations, etc., but these are so clustered together that it is impossible to arrive at the value placed upon any one item.

An important step is about to be taken by the Guernsey Railway Company, Limited, who have decided to substitute electric tramcars for the present steam cars on their line, which is nearly three miles long. The railway was constructed by the Guernsey Steam Tramway Company in 1879 and worked by them until 1888, when the service was discontinued, owing to the severe competition of the omnibuses. The present company acquired the tramway shortly afterwards, and have since been seeking a cheaper method of traction, which they believe to have found in a direct system of electrical traction. The local government board has given permission for the erection of overhead wires.

BOSTON.

A Victory Over the Snow.—Taxing Corporations for Use of Streets.—Fire Department Report.

DURING the recent severe snow storm in Boston, the electric cars may be said to have won in the battle with the elements. Not a single car was ordered off, but assisted by a number of small electric ploughs and brushes, they managed to keep fair time all through the blinding storm. There has been sufficient experience with snow storms now in Boston to prove that electric car systems can be made to successfully cope with the heaviest storm, and that all that is necessary is good management in the providing adequate ploughs and brushes, and getting them out on the line before the snow has a chance to solidify on the tracks. The fight must be begun with the commencement of the storm and no fear need be entertained about the successful running of the cars. The maxim might well be "Look after your tracks, the current will take care of itself."

It is evident that one of the matters before the legislature that will cause most discussion is the measure relating to the taxing by cities and towns of corporations using the streets and highways. There is a tendency to assess the tax upon the dividends of the corporation, exempting from such tax a certain per cent. of the earnings, which would be equal to a fair rate of interest upon the capital invested. One plan that has been proposed is that when there is a dividend of over 10 per cent. for a street railway corporation the fares shall be reduced accordingly. There is a strong possibility that the poles of the telegraph and telephone companies will be allowed to go free from this tax because of the complications that would almost necessarily result from the interstate connections of these companies. As far as street railways are concerned, it is thought that this proposed tax would diminish dividends, rather than increase the price of fares.

An extract from the report of the commissioners in Boston's Fire Department may be found interesting, as comparing the causes of fires, and showing how few can be attributed to the "deadly" electric light wire. The table showing the different causes of fires and alarms since May 1, 1890, includes 17 accidental automatic, 94 needless, 14 false, 5 out of town fires, 31 bonfires, 10 soot in chimneys, 33 from careless use of lamps, candles, etc., pipe or cigars, smoking, and clothes too near stove, 20 because of defective flues, stovepipe, grate or furnace, 17 electric wires, 13 fireworks, 29 from gas, 13 incendiary and 12 supposed to be, 2,953 from the use of kerosene oil, 15 matches and rats, 39 matches and children and 22 careless use of matches, 27 overheated stoves, furnaces and steampipes, 25 spontaneous combustion, 90 unknown, 42 by sparks. Five alarms were given by mistaking smoke or steam for fire.

The following extract may also be found interesting: "The present plan of running the wires of the various electrical systems through our streets is one of the most formidable of the problems with which the department has to contend, and its complications are constantly increasing. While these systems have become institutions that we cannot spare, a further regulation of them is required in order to secure the greatest good of the greatest number. Electric wires are not only active agents in causing fires, but some of these lines are so thickly run in front of buildings as to render it almost impossible to raise ladders for ventilation, carrying up hose or saving life. It might be a proper question of public policy to inquire whether in many such instances the wires might not be carried over the buildings, instead of alongside, until such time as the city shall get ready to order the wires underground. An essential weakness of the ordinance, creating the office of inspector of wires is, that the fire alarm telegraph has been divorced from the fire department. This act seems not to have been considered in the light of experience. While the present inspector understands the needs of the department and the relations of the fire alarm telegraph to other systems, the future, under the present arrangement, is fraught with menace to the best interests of the city and this department, which is the opinion not only of the fire commissioners, but of the inspector of wires as well."

BOSTON, March 8, 1891.

Society and Club Notes.

NEW YORK ELECTRIC CLUB.

At a regular meeting of The Electric Club, held Thursday evening, February 26th, 1891, it was voted to admit new members during the succeeding three months, upon the payment of one-half the initiation fee. This offers memberships as follows:

Active—$20 Initiation fee, and $40 yearly dues.
Associate—$10 " " $20 "

The object of this change is to rapidly increase the membership of the club, the limit of which has been raised to 1,000.

It is hoped that members will take advantage of this opportunity to bring their friends into the club.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the Institute on March 17, at the headquarters, 12 West 31st, Mr. J. J. Carty will read a paper entitled "Inductive Disturbances in Telephone Circuits." This subject is one of the greatest technical and practical importance, and could not be in better hands. Moreover, telephonic topics rarely offer themselves, and the art is not one in which there are to-day many experts familiar with the deeper problems of telephonic research.

Secretary Pope has just issued a title page and an excellent table of contents and index for Vol. VII of the *Transactions*. With this is also given an excellent steel portrait of Mr. Edward Weston, the fourth of the Institute's presidents. In keeping with his practice hitherto, Mr. Pope has begun the new volume of *Transactions* by issuing the parts in cover of a new tint. The double number for January and February contains Mr. Kennelly's admirable paper on "Inductance," Mr. Berliner's interesting description of his gramophone, and the valuable discussion on inductance and its new unit, the "henry."

NEW YORK TELEGRAPH CLUB ELECTION.

At the annual election of the New York Telegraph Club the following officers were elected for the ensuing year: President, E. E. Brannin (re-elected); first vice-president, Richard Kane (re-elected); second vice-president, Thomas J. Dunn; third vice-president, James I. Buxton; recording secretary, J. Clayton Watts; financial secretary, John R. Powers; treasurer, John Brant; librarian, L. E. C. Moore.

Personal.

MR. MYRON D. LAW.

The above-named electrical engineer has just been put in charge of the arc lighting work of the Edison General Electric Co., with headquarters for the present at Schenectady. Mr. Law began his electrical career a long time ago. He became connected with the old Telegraph Supply Co., of Cleveland, in 1877, having previously been engaged in general electrical work, such as it was in those days. He was sent to San Francisco to renovate the electrical work in the Baldwin Hotel, and then took hold of the San Francisco Telegraph Supply Co. About 1877-8 the first 12,000 c. p. Brush machine arrived out on the Coast and was put on exhibition. In the spring of 1878 they received the first four-current, four-light Brush machine, which was put up in the Palace Hotel courtyard. On September 16, 1878, Mr. Law started the first 16-light Brush machine for commercial work, with lamps rented at the modest price of $10 apiece per week, six nights a week, till 12 o'clock only. Soon after this the California Electric Light Co. was organized with a capital stock of $5,000,000. In 1880, after this very successful pioneer work, Mr. Law came East, and was associated with Mr. C. M. Rowley as assistant superintendent of the New England Brush Co. He was then sent to Philadelphia and there acted as the company's agent. In 1881 the Brush Co., of Philadelphia, was organized, and there Mr. Law stayed, through all the company's growth and changes, until 1890. He then accepted an invitation to take charge of the electrical reorganization of the Denver Consolidated Electric Co.'s plant at Denver, Col., and there remained until the present time. Mr. Law has had an experience in arc lighting work that is probably unsurpassed in this country.

ELECTRICITY HEALTHFUL IN ST. PAUL.

In response to a request from the Thomson-Houston Co., the board of health furnished them the information that during the past five years there have been 513 deaths from violence, none of which, however, as either directly or indirectly attributable to electricity.

Appointments, Etc.

Mr. John A. Seely has been appointed by the city council of Wheeling, W. Va., its electrical engineer for the purchase and equipment, &c., of its new municipal lighting plant, on which, it is said, $100,000 may be spent.

Manager Wallace G. Riggs, of the Meriden telephone division, is to be removed to New Haven, where he will be the superintendent of the operating department of that division, having charge of the switch boards, testing of the wires and of the electrical department of the office.

A. W. Ives, manager of the Southern New England Telephone Co. for the Ansonia district, has resigned to go to Boston, where he will pursue studies in electricity.

S. H. Bassett, son of R. M. Bassett, the extensive manufacturer of Birmingham, Conn., has severed his connection with the concern there, and will go into company with Stanley & Hall, manufacturers of electrical supplies in this city.

Mr. W. Hazen, who was for 15 years assistant publisher of *The Evening Post*, of this city, has vacated the business managership of *The Electrical World* after a four months' incumbency.

Mr. J. H. Passmore has resigned his position as inspector for the Edison Co. to accept that of electrician for the Rapid Transit Street Railway Co., of Newark, N. J., for whom he constructed the road on behalf of the Edison Co. The road has started off in admirable running order.

Metal and Supply Market.

IMPORTANT REDUCTION IN THE PRICE OF ALUMINUM.

The change in price list announced for their aluminum by the Pittsburgh Reduction Co., of Pittsburgh, Pa., is worthy of special note, and indicates very significantly the rapidity with which the metal is coming to the front. In writing us about this change, the company say: "The facts in the case are that we have come to the conclusion that in order to develop the larger market which we feel confident will surely open up upon reducing the price of aluminum to $1 per lb., it is best to make this rate for any quantity. At this rate, aluminum, which is nearly four times lighter than nickel or German silver, is a much cheaper metal to use than either of them, and is at such a price that it can be economically used for many purposes, being nearly as cheap as copper."

THE NEW D. E. MERITENS PRIMARY BATTERY.

For the past few days, writes our London correspondent, English and French newspapers have dwelt upon a great discovery of M. de Meritens in the shape of a galvanic battery. The inventor read a paper recently before the Societé Internationale des Electriciens, more or less descriptive of his apparatus, but he succeeded in convincing his hearers, who for the most part were not electricians, that he had solved effectually the great problem of the cheapness of electricity. The figures given during the address were too vague to be serious, and time must elapse before an unprejudiced statement is forthcoming as to the actual value of the battery.

M. de Meritens claims to have succeeded in rendering the galvanic pile absolutely constant as a source of electricity, by employing on the one hand pure zincs, and on the other, as the positive electrode, a plate of carbon perforated and covered on the side facing the zinc, with a sheet of platinized lead, the exciting liquid being water mixed with sulphuric acid. A battery was produced which, being short circuited, gave during an hour ana d half a constant current of 33 amperes. It is impossible to tell what would be the output under normal conditions, or at its maximum power over a given external circuit, or what would be the consumption of zinc and acid per effective horse hour or kilowatt hour. According to M. de Meritens, we should obtain electrical energy and hydrogen, which could be collected and utilized, by the expenditure of pure zinc and sulphuric acid for the formation of sulphate of zinc, the composite electrode of platinized lead and carbon remaining unattacked. The sulphate of zinc would then be treated electrolytically, plates of iron being employed as the anode so as to reduce to a minimum the counter electromotive force of decomposition of the electrolyte. The products of the operation, for which motive power is, of course, employed, would be on the one hand pure zinc, which would serve for the mounting of other elements, and on the other hand, sulphate of iron, the marketable value of which varies with the demand.

The Berlin municipality has lately come to the following decision: That no more concessions will be granted for the construction of high level street electric railways, or for electric tramways requiring overhead conductors.

Reports of Companies.

WESTINGHOUSE INTERESTS.

Mr. George Westinghouse announces a further extension of the time for subscriptions to the preferred stock of the Westinghouse Electric Co. to March 20. Interests on the Switch and Signal Co. bonds will be paid on the presentation of coupons.

STATEMENT OF THE BELL TELEPHONE CO.

The Bell Telephone Co. makes the following statement showing the movement of instruments for the month ended Feb. 20, and two months to date :

Month Feb. 20.	1891.	1890.	Increase.
Shipments	6,072	4,298	1,774
Returned	3,276	2,261	1,015
Net output	2,796	2,037	759
Since Dec. 20.	1890-91.	1889-90.	
Shipments	10,237	7,640	2,597
Returned	6,394	4,502	1,892
Net output	3,843	3,138	705
Instruments in use Feb. 20	485,473	446,879	38,594

STOCKS AND BONDS.

SCRANTON, PA.—Mr. Nicholas Kiefer has secured the charter and franchise of the South Side Electric Light, Heat and Power Co., of Scranton, having bought out the other members. This franchise covers the entire city, of which only the centre is now supplied with electric light, and Mr. Kiefer asserts that there is no better opening in the country for a plant of 5,000 incandescent, and 300 arc lights, and urges capitalists to join him in the undertaking. He will be glad to hear from any one desiring to become interested.

HELENA, MONT.—The Helena Electric Railway Co. has mortgaged its property to the Old Colony Trust Co., of Massachusetts, for $500,000, of which $150,000 is negotiable immediately.

MINNEAPOLIS, MINN.—The Minneapolis Street Railway Co. and the Minneapolis, Lyndale and Minnetonka Railway Co. have issued, jointly and severally, 5 per cent. bonds to the amount of $3,093,000, due Jan. 15, 1919. The subscription list was opened at the office of J. Kennedy, Tod & Co., on March 4. Application will be made to have these bonds listed on the Stock Exchange.

THE LYNN AND BOSTON RAILROAD CO. have received authority to increase their capital stock to $1,000,000, for the purpose among others of further equipping the road with electricity.

NILES, O., has reached her limit in bonded indebtedness ($16,000) and if the question of water works or electric light is decided in the affirmative, a special act of the Legislature will be necessary to grant permission to raise the funds.

HOPE, ARK.—The Town Council has been negotiating a sale of the water and electric plants, which had been constructed at a cost of $15,000, to a stock company, for the alleged purpose of enlarging and improving the same. It is proposed to give the company a thirty-year franchise. The company was to be allowed to charge an average of $10.00 to families. The present cost of operating for all purposes is $3,400 per annum and free water to citizens. Judge Mitchell enjoined the sale, and the mayor and aldermen gave notice of application to dissolve the injunction.

ELECTIONS.

OLD TOWN, ME.—At the annual meeting of the Old Town Electric Co., the following members were elected directors: Arthur S. Palfray, Salem, Mass.; Alphonso A. Wyman, West Acton, Mass.; P. H. Alexander, Ferdinand A. Wyman, Warren S. Hill, Hyde Park, Mass.; N. H. Colton, James H. Burgess, Old Town.

NEWPORT, R. I.—Mr. John P. Sanborn has been elected president of the Edison Illuminating Co. A semi-annual dividend will not be paid. The company has declared but one half-yearly dividend.

DIVIDENDS.

The American Waltham Watch Co. has declared a semi-annual dividend of 4 per cent. payable March 2.

KALAMAZOO, MICH.—The City Electric Light Co. has declared a 5 per cent. dividend on stock taken prior to January 1.

PROPOSED NEW YORK BOARD OF TELEGRAPH COMMISSIONERS.

The establishment of a board of three telegraph commissioners is contemplated in a bill put in by Mr. Stein, of New York. They shall be expert telegraphers and be appointed by the Governor for two, four and six years, respectively. They must examine and license successful applicants for telegraphic work on the State railroads. No road, under the bill, can employ any telegraph operator under eighteen years of age or who has not passed the examination of the board. The annual salary of each commissioner is placed at the handsome sum of $5,000. The annual expenses of the board must not exceed $25,000, and the Comptroller must collect the money from the roads interested.

MR. S. E. BARTON'S CLEVER ADVERTISING SCHEME.

Detective Bedford, of Atlanta, has arrested S. E. Barton, president of the Electric Mutual Insurance Company, and agent of the Royal Insurance Company, of Liverpool, the Germania, of London, and the Pennsylvania, of Philadelphia.

It appears that Mr. Barton, who was on his way to Florida, with Luther Stieringer, the expert, to shoot game, was in Atlanta several days, stopping at the Kimball House, and that while there, he wrote up several insurance policies, in violation, it is claimed, of the State law, which requires all insurance companies, doing business in the State, to deposit $25,000 and to take out a license. The Electric Mutual has been given big advertising all over the country by the Associated Press, and some of Mr. Barton's countless friends in the electrical business, who know how slick and shrewd he is, are admiring him for the manner in which he has thus secured a big, free "ad." The case will be decidedly interesting owing to the prominence of the defendant.

ANTI-TELEPHONE LEGISLATION.

The directors of the Telephone Subscribers' Association of the State of New York, resolved at a recent meeting to commission F. S. Gardner to arrange at Albany for the introduction into the Legislature of last year's telephone bill and to exert every effort to secure the passage of the measure.

THE TELEPHONE IN SWEDEN.

State papers recently published in Sweden show that great progress has been made in telephony. There are now 3,338 wires worked by the government, and the total length, including lines operated by private enterprise, is 46,090 kilometres.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of March 7, 1891, from New York, Boston and Washington ; Pittsburgh, March 6.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEB. 24, 1891.

Accumulators :—

Secondary Battery, S. C. C. Currie, 447,279. Filed Nov. 18, 1890.
Electrode comprises an interior support, an exterior woven tube and a porous metallic substance or materials cast within the tube and around the support.

Alarms and Signals :—

Thermostat, A. M. Barron, 446,846. Filed Sept. 19, 1890.
Mechanical details of construction.

Police Signaling Apparatus, B. J. Noyes, 447,058. Filed July 28, 1887.
A system for the joint use of police and fire departments ; adapted for distinguishing between police-signals and fire-alarms. An independent receiving instrument is employed at the central station for the police signals together with means for including it in the line and simultaneously cutting out the police-signal receiver.

Police Signaling Apparatus, B. J. Noyes, 447,059. Filed July 28, 1887.
Designed for transmitting determinate signals—as a box number—special signals—as a wagon call—and variable signals—as the numbers by which the police officers are known.

Municipal Signal Apparatus, B. J. Noyes, 447,060. Filed Sept. 14, 1888.
In addition to apparatus at the sub-stations for transmitting various code-signals to a central station, provides mechanism at the sub-stations for transmitting impulses different from those employed in the code-signals, which shall operate an audible alarm or indicator at the central station, whereby an alarm may be made to respond to some of the signals and not to others.

Municipal Signal Apparatus, B. J. Noyes, 447,061. Filed Sept. 14, 1888.
Adaptation of induced or secondary currents to operate alarms or indicators at a central station.

Signal Box, B. J. Noyes, 447,062. Filed Sept. 11, 1889.
Consists in the combination with a signal-box and a key for operating it adapted to be inserted and withdrawn, of a piece of material arranged to be marked upon or embossed by the key.

Non-interference Fire Alarm Signal-Box, W. H. Kirnan, 447,074. Filed March 1, 1889.
Employs a motor for operating signalling mechanism, a handle for starting the motor, a mechanical disabling device for the starting-handle controlled by armature of electro-magnet, and a resetting device operated by the motor at the conclusion of a signal.

Annunciator and Indicator System, J. E. A. Miller, 447,195. Filed Sept. 5, 1890
Details of construction and circuits for an annunciator and indicator system for hotel use and other similar purposes.

Clocks :—

Independent Electric Clock, W. J. Dudley, 447,105. Filed Oct. 18, 1890.
Relates to clocks of the class in which time is measured by a pendulum or balance, while the hands are moved by an electro magnet which is also employed to impel the pendulum or balance.

Dynamos and Motors :—

Electric Motor, L. Gutmann, 446,864. Filed Sept. 18, 1890.
An alternating, pulsating or intermittent current motor. Invention consists in using such currents in the field magnets, whose several cores are suitably subdivided to prevent heating, creating a magnetic field which by induction acts on one or more close-circuited ring-windings, and generating in a single winding of the armature secondary currents differing in quantity and lag from one another by the external application of one or more short circuiting brushes.

Galvanic and Thermo-Electric Batteries :

Galvanic Battery, M W. Robinson, 417,016 Filed June 6, 1890.
Battery shown has four porous cups containing separate positive elements immersed in a single outer vessel containing one continuous negative element.

Lamps and Appurtenances :—

Socket for Incandescent Electric Lamps, J. M. Orford, 446,995. Filed Nov. 18, 1890.

Relates particularly to the switch for making and breaking circuits.

Regulator for Electric Circuits, T. M. Edwards, 447,177. Filed Nov. 5, 1890.

Relates to employment of a liquid resistance in a regulator applicable especially for controlling the circuits of several sets of electric lights in a theatre or other audience room.

Apparatus for Flashing and Exhausting Incandescent Electric Lamps, W. E. Nickerson & A. Berrenberg, 447,256. Filed June 20, 1890.
Relates to a system of apparatus for exhausting a large number of lamps simultaneously, and consists essentially of means for automatically cutting off the current from the lamp circuit whenever an influx of air occurs either through breakage or through inadvertent manipulation.
Claim follows :
In combination, one or more electric lamps, connected to an exhaust apparatus, a main circuit for flashing the filaments of said lamps, a local circuit including a circuit closing device operative upon an admission of air to the exhaust apparatus, and a cut-out for the main circuit, controlled by said local circuit.

Vacuum-Pump, A. Berrenberg & W. E. Nickerson, 447,273. Filed May 10, 1890.

A mechanical pump applicable to the exhaustion of incandescent lamps.
Claims follow :
1. In the jacketing-spaces of a vacuum-pump, deaerated oil as a sealing medium.
2. In a vacuum-pump the combination of jacketing-spaces sealed with deaerated oil, and an apparatus having passage-connection with said spaces and adapted to deaerate the oil and force it through the jacketing-spaces.

Vacuum-Pump, A. Berrenberg & W. E. Nickerson, 447,274. Filed May 10, 1890.
Claim follows :
The combination, in a vacuum pump, of a piston and cylinder, with a filling of deaerated oil adapted to fill all the space under and about the piston within the cylinder at the completion of the stroke of the piston, and thus completely expel all air.

Vacuum-Pump Connection, A. Berrenberg, 447,275. Filed June 2, 1890.
In connection with a system of vacuum-pipes, combines a socket-piece adapted to receive a key or the socket-end of a fork, and having passage-connections with the vacuum system, with a jacketing-piece having passage-connection with a jacketing-system as described.

Metal Working :

Method of and Apparatus for Electric Welding, H. Lemp & L. M. Schmidt, 446,974 Filed July 23, 1890.
Relates to the welding of longitudinal joints ; particularly applicable to jointing strips, bars &c., side by side.

Electric Welding Apparatus, M. W. Dewey, 447,104. Filed Nov. 1, 1890.
Especially applicable to the heating and welding of curved forms, as rings, hoops, tires, etc.

Miscellaneous :—

Binding-Post, C. A. Lieb, 446,871. Filed Sept. 19, 1890.
Details of design and construction.

Fuse-Block, A. P. Seymour, 446,895. Filed July 26, 1889.
Designed to avoid the loosening of the fuse in its clamps ; provides a spiral take-up spring which allows a number of turns backward of the clamp screw without releasing the grip of the clamp upon the fuse.

Automatic Cut-Out, J. P. Tirrell, 446,902. Filed June 4, 1888.
Designed for automatically cutting out a branch-circuit in case of an accidental ground connection caused by the derangement of the terminal points or otherwise ; especially applicable to electric gas-lighting systems.

Cut-Out, S. D. Field, 446,966. Filed May 28, 1890.
A safety appliance for electric circuits.
Claim 1 follows :
A potential cut-out for electric circuits, consisting of an enclosed fluid conductor, such as mercury, connected to the circuit, a grounded terminal adjacent to such conductor, and an interposed gaseous body of relatively higher conductivity than air.

Electric Time-Lock, M. I. Flowers, 446,967. Filed May 5, 1890.
Consists in combination, with an electric motor, of a time dial, a check bolt, and intermediate connections, by which at a predetermined time the check bolt will be actuated or released to permit the locking mechanism proper to be actuated.

Electro Heating Apparatus, C. E. Carpenter, 447,023. Filed Sept 27, 1890.
Applicable to smoothing irons and similar purposes. Combines with the heated surface-plate and resistance employed, a coating of enamel or its equivalent securing the resistance to, but insulating it from, the heated surface-plate.

Vacuum-Core for Electrical Heating Devices, H. R. Butterfield, 447,127. Filed June 25, 1890.
Adapted to smoothing irons. Inventor makes use of a removable hollow shell, which is exhausted of air and contains the resistance.

Electric Heater, J. I. Ashbaugh, 447,143. Filed March 15, 1890.
Employs a solid central bar or part of clay or its equivalent, a coil or wire closely wrapped about such bar or part, and a heat conducting envelope surrounding the coil, the envelope being a non-conductor of electricity.

Railways and Appliances :—

Electric Railway Signal, E. T. Harvey, 446,917. Filed Nov. 6, 1888.
Adapted to enable the engineer of a train to receive an "O. K." signal at different or predetermined points along the line of a road, the road being divided into sections, each having an independent circuit.

Trolley for Electric Railways, S. H. Short, 446,981. Filed Nov. 12, 1890.
Instead of a somewhat deeply grooved trolley wheel as usually employed, the inventor uses a contact roller with a cylindrical periphery and ears or guards projecting alongside the roller beyond its periphery.

Trolley-Wire Hanger, C. H. Macloskie and W. E. Baker, 446,985. Filed Nov. 18, 1890.
Consists of a hollow conical metal case, open from top to bottom and having an annular rib or flange at or near its larger end. An insulating cone of porcelain or other material is adapted to fit against the interior of the conical metal case.

Cross-Over for Trolley Lines, S. H. Short, 447,208. Filed Oct. 22, 1890.
Relates to means for carrying one trolley line or supply conductor over or across another in such a way as to allow the trolley to pass freely on either line.

Electric Railway System, C. J. Van Depoele, 417,215. Filed March 7, 1889
A converter system of distribution and supply for electric railways enabling the energy to be transmitted from the power station at high potential.
Claim 1 follows :
A system of supplying and distributing currents for electric railways, comprising working conductors along the line of way, a circuit supplying currents of relatively high potential, main tension reducing devices connected with the high tension circuit and continuously supplying currents of lower potential to the working conductors, and auxiliary tension reducing devices distributed along the line of way and provided with automatic means for closing the circuits and rendering the auxiliary converters operative upon a fall of potential in the working circuit.

Current-Controlling Device for Electric-Railway Cars, J. C. Chamberlain 447,230. Filed Sept. 9, 1889.
Current regulating apparatus for storage battery cars.
Claim 1 follows :
The combination, with an electric circuit, of groups of batteries, a motor and a regulator having series of contacts for changing the grouping of said batteries and, co-operating therewith, separate series of contacts adapted to connect said batteries with opposite poles of said motor, all of said contacts being mechanically connected, so as to move together.

Electric-Motor Mechanism, S. E. Mower, 447,255. Filed May 31, 1890.
Applicable to electric railway cars. Consists, in connection with a car axle and a continuously running motor, of speed reducing gears connecting the armature shaft with the axle, one of the gears being loose on the axle, a second set of speed reducing gears connecting the armature shaft with the axle, one gear of the second set being loose on the axle, and a double bevelled cone friction-clutch mechanism secured on the axle intermediate of the loose gears of the speed reducing gears.

Electric Railway, R. M. Hunter, 447,283. Filed Dec. 6, 1890.
Relates to the position of an overhead trolley wire with respect to the tracks at curves. At a curve the inventor places the trolley wire somewhat to one side of the centre of the track and towards the outer rail of the curve with a view of diminishing lateral play of the trolley pole when a car is rounding a curve.

Telegraphs :—

Telegraph Transmitter, S. W. Smith, 447,166. Filed Nov. 13, 1890.
A key-board transmitter for Morse signals.

Telegraph Apparatus, J. A. Parker, 447,198. Filed Feb. 28, 1890.
Improvement in devices of manipulation for the telegraph system known as "Stenograph" for which patents were granted to M. M. Bartholmew, No. 215,559, May 20, 1879, and No. 255,910, April 4, 1882.

Telephones and Apparatus:—

Magneto-Electric Signal Device, N. B. Ginochio, 447,045. Filed May 9, 1890.
A magneto-electric call-box adapted to telephone and telegraph service.

Telephone, E. J. P. Mercadier, 447,194. Filed May 26, 1890.
A telephone having its diaphragm adapted to respond only to a tone of a given pitch, and applicable for use in multiplex and harmonic telegraphy. Inventor calls it a "Monotelephone."

Transmitter Circuit, A. C. White, 447,220. Filed July 24, 1890.
An arrangement of circuits and devices providing for the common use by a number of telephone transmitters of a single battery or source of electricity.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 3, 1891.

Alarms and Signals:

Electrical Annunciator, W. E. Cram, 447,558. Filed May 23, 1890.
An annunciator adapted for hotels or similar uses Designed for the employment of relatively feeble currents and to reduce dimensions and consequent space required.

Electrical Door-Bell Pull, L. W. Cleveland, 447,748. Filed Dec. 1, 1890.
Adapted for increased protection of the contact parts from the action of the weather.

Conductors, Conduits and Insulators:—

Electrical Subway, J. C. Reilly, 447,850. Filed May 20, 1890.
Composed of one or more ducts, within one or more of which is placed a leading-in device consisting of a longitudinally slotted tube fixed to the interior wall of a main duct or passage: within such interior duct is a link composed of a metal plate slightly greater in width than the diameter of the tube so that one edge projects downward through the longitudinal slot; the conductor or cable to be drawn into position is attached to the protruding edge of the link-plate above mentioned.

Distribution:—

Electric-Lighting System, B. B. Ward, 447,482. Filed May 5, 1890.
Consists in an arrangement of circuits and of devices for equalizing the resistances in several multiple-arc branches, as in arc or incandescent lighting.

Electrical Transformer, R. Kennedy, 447,569. Filed Dec. 29, 1886.
The transformer consists of insulated copper conductors for the primary and secondary circuits enclosed throughout their length within an outer sheathing of iron wires or plates, in the form of a cable which may be coiled up or bundled in any convenient manner. Connections may be made by any number of points along the length of the cable for obtaining any desired electromotive force less than the maximum.

Dynamos and Motors:-

Electric Dental Motor, H. H. Blades, 447,291. Filed March 23, 1888.
Relates especially to means for manipulating or regulating the currents of an electric motor by mechanism located at the hand-hold at the end of a flexible shaft such as is usually employed with dental machinery.

Commutator Brush, E. W. Rice, Jr., 447,352. Filed Nov, 28, 1890.
Claim 1 follows:
A carbon commutator-brush having a metal coating gradually decreasing in thickness toward the wearing surface of the brush.

Dynamo-Electric Motor or Generator, E. Thomson, 447,384. Filed Oct. 20, 1890.
Comprises improvements in the means for connecting the armature wires with the commutator segments, and in means for binding together the projecting ends of the armature-windings into a fairly rigid mass with the armature body.

Commutator Brush, W. Main, 447,469. Filed Dec. 23, 1889.
Consists of a series of contact plates arranged to be held in contact with the commutator by centrifugal force when used with a stationary commutator and rotating brush-carrier, or by a spring when the brush-carrier is at rest or moving slowly; brush consists of a series of parallel plates inclined to the surface of the commutator with their edges parallel with the plane of rotation.

Electric Motor, E. B. Meyrowitz & F. Buchhop, 447,734. Filed May 21, 1890.
Relates to portable motors for light work, and consists in design and construction adapted for the enclosure of the motor in a substantially spherical shell or casing.

Lamps and Appurtenances:

Incandescent-Lamp Socket, H. J. Gutman, 447,315. Filed Sept. 29, 1890.
Relates chiefly to the contact points, and is applicable to other purposes as well as to lamp sockets.

Electric-Arc Lamp, E. Thomson, 447,383. Filed Feb. 16, 1884.
Designed mainly to provide for an accurate alignment of the upper and lower carbons, and thus to permit the use of carbons of relatively small diameter.

Universal Joint for Incandescent-Lamp Brackets, E. C. Bennett & E. C. Freeze, 447,486. Filed Apr. 4, 1890.
Enables an incandescent lamp to be adjusted to any position.

Electrode for Electric-Arc Lamps, A. C. Siebold, 447,702. Filed Oct. 30, 1890.
A negative electrode designed to be practically indestructible.
Claim 1 follows:
In an arc lamp, a negative electrode consisting of a metallic bar or rod having a layer of carbon upon one end enclosed or covered by a thin metallic plating.

Electric-Arc Lamp, L. H. Buchanan, 447,746. Filed July 8, 1890.
A lamp of the class employing carbon discs instead of rods or pencils; the discs are in sector form and are placed in a horizontal plane.

Medical and Surgical:—

Rheostat, J. O'Meara, 447,494. Filed Nov. 15, 1890.
A rheostat adapted to the control of currents for electro medical purposes.

Miscellaneous:—

Electric Heater, C. H. Rich, 447,353. Filed Sept. 15, 1890.
Consists of a heat-absorbing core provided with washers of an absorbing and radiating nature and coils of insulated wire about the core and between the washers; the heat is absorbed from the inner part of the coils and brought to the surface for radiation.

Electric Time-Lock, J. H. Kaiser and A. B. Ledwith, 447,409. Filed May 15, 1890.
For safes. Consists in a locking-bolt and means for operating it, an electro-magnetic device co-operating with the clock-movement in operating the bolt, and a device by which the bolt may be operated from the outside of the door.

Electro-Magnetic Cut-Out, G. Taintor, 447,529. Filed Aug. 16, 1890.
A safety device. Designed to ground a line at various points during dangerous disturbances and thus shunt heavy currents away from fuses and instruments; also facilitates the testing of lines.

Electric Cut-Out, G. C. Gammon, 447,676. Filed July 2, 1889.
Adapted to break an electric circuit after a pre-arranged period of time when the same becomes grounded or otherwise closed, thus preventing waste of battery.

Electric Snap-Switch. G. W. Hart, 447,728. Filed Aug. 21, 1890.
Design and construction for simplicity.

Railways and Appliances:—

Electric Railway, W. H. Knight, 447,332. Filed Mar. 18, 1886.
Relates to a conduit system of electric railways and includes a supplementary frame on a car or locomotive for supporting the motor and contact device. The supplementary frame is journaled on the axles, supports the car through intermediate springs, and carries the motor.

Conduit for Underground Trolley Wires, H. J. Medbery, 447,338. Filed Nov. 21, 1890.
Conduit is made of wood pulp or other fibre, and is either moulded into shape under great pressure, or made from sheets which may be bent and fixed into shape under the influence of heat and pressure.

Turn-Out and Crossing for Line Conductors, S. H. Short, 447,496. Filed Apr. 12, 1890.
Particularly designed for roads employing two overhead or underground trolley conductors in a complete metallic circuit.

Trolley for Electric Railways, W. J. Calvert & W. P. Wiswall, 447,632. Filed Aug. 27, 1890
Provides an attachment for the trolley which will clear ice from the conductor, and will also serve as a guard to keep the trolley from leaving the conductor.

Electric Motor, R. W. Traylor, 447,704. Filed May 21, 1890.
A motor especially adapted for electric cars.
Claim 1 follows:
In an electric motor, the combination, with the pole-pieces of the field magnets, of cores arranged between the yokes and the parallel projections of the pole-pieces, each magnet being wound with a separate coil, and a countershaft extending between and parallel with the cores of said magnets.

Telephones and Apparatus:—

Telephone-Switch System, C. C. Gould, 447,426. Filed Oct. 10, 1887.
Designed for use in telephone exchanges and intended to facilitate and expedite manipulation.

Telephone-Exchange Apparatus, F. G. Beach, 447,485. Filed Feb. 4, 1888.
Consists in devices and arrangements of circuit intended to reduce the number of lines required in metallic circuit exchanges by combining as a metallic circuit the lines of any two subscribers conveniently located.

SHEARING SHEEP BY ELECTRICITY.

The suggestion which was made some short time ago that electricity should be utilized for the shearing of sheep, has, it is stated, been promptly taken advantage of by the Australian sheep farmers. A very effective installation has just been made on the Raukapuka estate for actuating Wolseley sheep-shearing machines by motors. Ten of these machines are now electrically worked there, and it is calculated that the extra value of the clip of 13,000 sheep has nearly recouped in one season the whole cost of putting up the machines. In the Raukapuka plant, a turbine drives the dynamo, and an overhead wire conducts the current to the motor which drives the shafting in the woolshed. Special arrangements are made to keep the speed of the shafting constant, though the work being done continually varies. It deserves mention that the idea originated two or three years ago with Mr. George H. Guy, the secretary of the New York Electrical Society.

A NEW SUBWAY SCHEME FOR NEW YORK CITY.

A bill has been introduced in the New York Senate to wipe out the Board of Electrical Control and establish a new Subway Commission, which may spend $3,000,000 of city money on new subways in any year and which would practically come into possession of such subways as now exist under private control.

LIGHTING AN IMPORTANT RAILWAY TUNNEL.

A good deal of satisfaction is expressed by commuters and other travelers on the Delaware, Lackawanna and Western Railroad at the announcement that Samuel Sloan, the president of the company, has decided that the Bergen tunnel shall be lighted by electricity. The work will be carried out by Mr. Paul H. Brangs, the electrician of the Railway Co., who is already taking steps to carry out Mr. Sloan's ideas.

A COLOMBIAN CABLE.

An important contract has been signed by the Colombian Government for the construction of a sub-fluvial telegraph line from the head of navigation on the Magdalena River to Carthagena and Barranquilla, and a submarine cable from these points to Colon, where connection will be made with the lines already communicating with the United States and Europe. The work is to be completed within two years and a half, and will put Colombia in good telegraphic connection with the rest of the world.

Legal Notes.

THE AMERICAN RAPID TELEGRAPH CO. DEFEATED.

The appeal of the American Rapid Telegraph Company from the judgment of the General Term of the Supreme Court, in favor of the Board of Electrical Control in the suits brought to have the subway acts declared unconstitutional and void, has been decided, by the Court of Appeals, against the company.

AUGUST JOHNSON vs. ERIE TELEPHONE CO.

Suit for $15,000 damages has been brought by Mr. August Johnson, of St. Paul, Minn., against the Erie Telephone Co., for injuries received from being thrown from his buggy. He claims that his horse took fright at a telephone pole which overhung the street.

LOCAL ELECTRIC LIGHTING COMPANIES SUING NEW YORK CITY.

The Brush Electric Illuminating Company and the United States Electric Lighting Company have begun actions against the city for damages to their poles and wires. The former asks for $525,000 and the latter for $550,000. The suits are the outgrowth of the crusade against the poles and overhead wires made by the Commissioner of Public Works under orders from the Mayor in December, 1889, and following months. The poles and wires were removed on the ground that they were a menace to life.

The companies base their claims for damages on the losses they suffered through the interruption to their business caused by the breaking of the electric circuits with which they supplied private patrons. The city's defense will be that it has the right to regulate structures in the public streets affecting the life and health of the general public.

DANGEROUS WIRES AND POLES.

The Hudson County Grand Jurors have sent to Judge Knapp a communication stating that for months past the wires and poles of the Western Union Telegraph Company and of the Bell Telephone Company in many places in the county have been and still are a source of danger and injury to the persons and property of the people. They ask the court to abate the nuisance.

ELECTRIC SIGNAL LITIGATION.

A suit has been brought by the Electric Secret Service Company, of West Virginia, against the Gill-Alexander Electric Manufacturing Company, of Kansas City, Mo. The invention in dispute is an automatic electric signal, an appliance by which telegraph operators are enabled to signal any specific office without signalling all the other offices along the line. Edwin R. Gill is the inventor. The West Virginia Company allege that they bought the entire patent from Gill, and seeks to enjoin the Kansas City Company from manufacturing the article. Gill says that he sold the West Virginia company only a half ownership in the patent.

A TROLLEY WIRE INJUNCTION DENIED.

In the proceedings brought by John W. Decker and others, property-owners along the line of the Harlem Bridge, Morrisania and Fordham Railway Company, to prevent that company from adopting the trolley system of electrical transportation, on the ground that their consent was obtained by fraudulent representations, Judge Ingraham has refused to grant the injunction.

ANOTHER WESTERN UNION POLE INJUNCTION.—Upon the application of M. H. Oppenheim, counsel for William Meles, who resides at No. 146 West Seventy-first street, Judge Ingraham of the Supreme Court has granted a temporary injunction, restraining the Western Union Telegraph Company and the Fire Commissioners, from maintaining an unsafe pole in front of his residence, and from erecting or maintaining poles and wires on Seventy-first street, between Columbus and Amsterdam avenues. This is the third proceeding which has been instituted against the maintenance of poles and wires in that section of the city, and the tirade against such obstructions is gaining impetus.

UNIONTOWN, PA.—The injunction asked for by the Pennsylvania Railroad Company to restrain the Uniontown Electric Street Railway Company from running any cars, has been refused.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Dividends from advertising depend on the care and shrewdness with which the money is invested by the advertiser."

ELECTRIC MOTORS WITHOUT COMMUTATORS.

The Elektron Mfg. Co., of 79-81 Washington street, Brooklyn, has just issued a neat little brochure under the above title, and containing a great many testimonials as to the value and usefulness of their motors. It has the following pithy little preface:

It is well known that the average electric motor requires less attention and less skill to operate than any other machine from which power is obtained; and that people who have bought a good machine and are careful to give it a few minutes' attention daily according to instructions, have invariably found it satisfactory.

If everyone in charge of a motor was careful to give it a fair show this little brochure would never have been written, but what manufacturer has not had occasional experiences with people too careless to follow simple directions, or to prevent ignorant persons and small boys from meddling with the brushes and switches, yet who become dissatisfied with the resultant annoyances and condemn a machine that in other hands would have been a perfect success.

Nothing short of a machine that will take care of itself under all possible conditions will give such people entire satisfaction. Is it possible to make one?

Ever since the advent of electric power inventors have been working in this line. They have usually sought to abolish the commutator and brushes as being the parts requiring the most attention and most likely to be disarranged through accident or ignorance, but so far their efforts appear to have been unsuccessful, and it is more than probable that the commutator will always remain an essential part of both motors and dynamos where continuous currents are used.

Instead of attempting to do away with commutators and brushes we have attempted, and by correct design, self-adjusting brushes, self-oiling bearings, and a great reduction in speed have succeeded in entirely avoiding all the annoyances referred to. The motors run practically without attention and there can be no "monkeying" with the brushes. Patents have been granted to us for important features of the improvements.

The Perret motor has heretofore ranked with the best. With these improvements it stands unequaled.

The first motors equipped with the improvements mentioned have been in use nearly a year and have given unqualified satisfaction.

RAW HIDE PINIONS AT THE MORGAN ENGINEERING WORKS.

The New Process Raw Hide Co., of Syracuse, have received the following from the Morgan Engineering Works, of Alliance, O.:

"On Dec. 6th, 1890, you wrote inquiring whether the raw hide gears gave us satisfaction in regard to wear and noiseless feature and the need of no oil. The eight pinions were used on four motors, two 15 and two 20 horse power for operating two 25 ton cranes, for handling locomotives for the Pennsylvania R. R. Co. at Altoona, Pa. We must say they have given us the highest satisfaction and we have no complaint whatever to make.

"We have replaced on a large 10 ft. planer, steel bevel wheels with raw hide gears, and they have now been running over a year and a half, giving entire satisfaction and outwearing both bronze and steel.

"The reason we did not answer your letter previously, is that we desired a longer time to test these gears before giving you our opinion."

THE INTERIOR CONDUIT AND INSULATION CO.

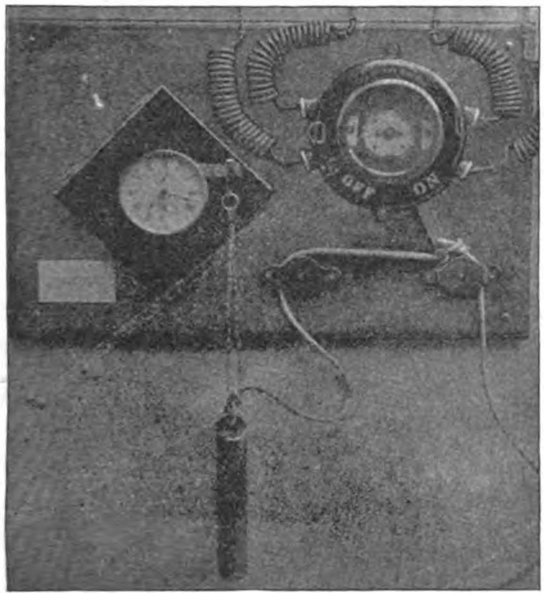
In THE ELECTRICAL ENGINEER of June 18th, 1890, appeared a full description of the methods employed by this company, which had at that time just issued its prospectus. It has now been found necessary, in view of the rapidly growing demand for the system, to open a branch office in Chicago. The unprecedented success of the company proves that the trend of popular opinion toward better and safer wiring is assuming the nature of a demand.

GIBSON UNINTIMIDATED.

The Gibson Gas Fixture Works, 1,426 Callowhill street, Philadelphia, have issued the following defiance, under date of March 5: "We will indemnify purchasers of our electric or combination fixtures against all infringement suits. The Trust threat is simply another desperate attempt to intimidate dealers."

THE AUTOMATIC CLOCK FOR LIGHTING CIRCUITS.

Some time ago, The Electrical Engineer described the automatic clock of the Electrical Engineering and Supply Co., of Syracuse, N. Y., for cutting out incandescent or arc lamps. The accompanying illustration shows the clock attached to an arc switch, as exhibited at the Providence Convention, where it attracted considerable notice. To set the clock, the sliding bar at the right is drawn out until it rests against the inclined track; the traveler is hung on the track, and, at the time set, the traveler rolls off, falling with sufficient force to throw any style of switch, and cut out the lamps. The clock is especially useful for cutting out loops at any hour, on all night circuits, thus avoiding the necessity of a patrolman to switch out lights.



The Automatic Switch Clock.

FEED WATER HEATERS IN ELECTRIC LIGHT PLANTS.

Mr. H. S. Cooper, the superintendent of the Conshohocken Electric Light and Power Co., has recently addressed the following very interesting statement to Warren Webster & Co., of Philadelphia, dealing with the question of feed water heating and steam economization:

In reply to yours inquiring as to the action of the "Vacuum" exhaust economizer and feed water heater, we would say that after three months' steady use, we are more than satisfied with it, as our acceptance of and settlement for it would prove.

Our feed-water is phenomenally rich in the sulphates and carbonates of lime and magnesia, in fact it is a veritable mineral water, and with our previous heater, gave us great trouble, clogging the heater and fouling the boiler, and as the heater was a tubular one, it was next to impossible to clean it of the adhering scale, and in consequence we could only get from 135° to 140° temperature of feed-water. Since using the economizer we have no trouble with scale in our boilers, in fact the old scale is gradually coming off. The annual inspection of our boilers was made last week by the insurance company, and they were pronounced in much better condition in regard to scale than a year ago, when using same water and the tubular heater. The deposit of lime, etc., in the economizer is so heavy that we are compelled to clean it every two weeks, and with the extra set of deposit plates you sent us we can do it *easily* in less than an hour and with the engines running, if necessary. With our old heater, all this or *nearly* all this deposit was in the *boiler*, and what *did* deposit in the heater we were unable to get out and it stayed there, preventing a thorough heating of the feed-water. With the economizer we find only a difference of 1° or 2° before and after cleaning it, we get a steady temperature of 210° *at the pump* when using the most water, and when using only a small quantity have found it as high as 211° at the pump, which would show *very* close to 212° in the economizer, and that with a perfectly free exhaust, or rather with a slight vacuum, as the difference in our exhaust is noticeable when we use the economizer and when we do not.

As you know, we were prejudiced against the "open" form of heater, owing to our fear that the oil in the exhaust steam would be carried back to the boiler in the feed-water. After a very close examination, we cannot find *any* trace of oil in our boilers, your arrangements in the economizer entirely clearing the water of the oil. We are also well pleased with the automatic feed and discharge valves on it; they give us no trouble, we turn the economizer on when we start and hardly look at it until we stop. In fact, for efficiency, simplicity, compactness and accessibility for cleaning, it is without a rival.

The writer has used or had in service *all* of the leading exhaust heaters on the market, and while many of them are excellent, there is not *one* good point in any of them that your economizer does not cover, and there are many points in the economizer that *none* of them have.

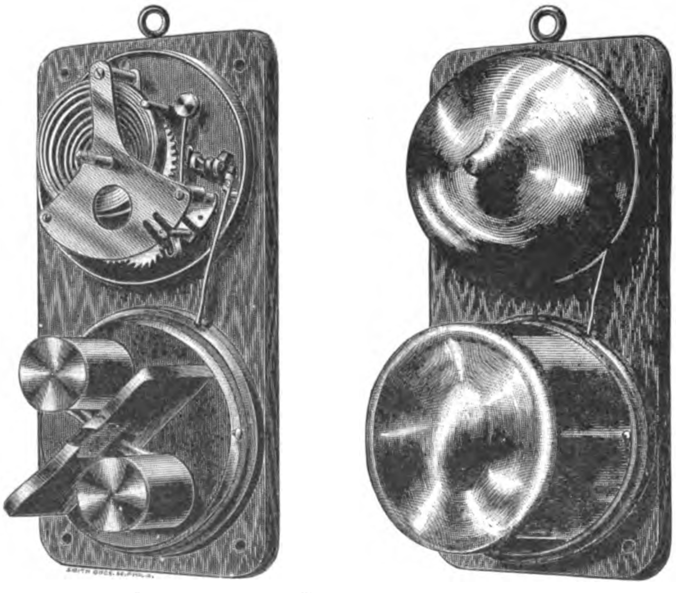
We shall be pleased to show ours to anyone at any time, or to take them to see any of the others you sold around here, and they all appear as to be as well pleased with theirs as we are with ours.

Of course, with a freer exhaust, and with hotter and cleaner feed-water, we are saving coal right along, a very nice interest on the money paid for the economizer, to say nothing of cleaner boilers.

A NOVEL FIRE AND HEAT ALARM.

The accompanying illustrations show the Iske automatic fire alarm, manufactured by Stoner, Myers, & Co., of Lancaster, Pa. Fig. 1 shows the device with the gong and case removed, the clock work, and means of starting it being visible; while Fig. 2 shows it as it appears hanging on the wall ready for use. The operation is as follows: The two cylinders shown at the bottom in Fig. 1, are connected by a tube which extends nearly to the bottom of the lower cylinder. This cylinder is partly filled with some liquid which will volatilize readily when relieved of pressure, and the whole (cylinders and tube) is exhausted of air, and hermetically sealed. It is then pivoted at some point on the tube so that the lower cylinder will just overbalance the upper, as shown. When, however, heat is applied, part of the liquid speedily evaporates, the pressure of the vapor forcing part of the remainder through the tube, into the upper cylinder, when it immediately overbalances the lower, and both rotate about the pivot. Their rotation is sufficient to set in motion the clockwork, and start the bell ringing.

The device can, of course, be adapted to electric bells equally well, but where it is not desired to sound an alarm at a distance, the clockwork is held preferable, on account of its simplicity, cheapness and portability. The clockwork is entirely encased by the gong, and is wound by means of it, so that no key is required.



Figs. 1 and 2.—The Iske Fire Alarm.

The alarms, unless specially ordered, are made to sound at 110° Fahrenheit. The apparatus is handled in this city by Frederick Pearce, 79 John street, this city.

THOMSON-HOUSTON PLANTS IN THE WEST.

The Western Isolated Lighting Department of the Thomson-Houston Electric Co., Chicago, report the following recent sales:— Calumet Distilling Co., New Chicago, Ill., 200 light incandescent plant (increase). Bradner, Smith & Co., Chicago, 20 light arc plant (increase). Woodcock & Loring, Clifton House, Chicago, 12 arc light plant; Liss & Rickeman, 75 North Clark Street, Chicago, 120 light incandescent plant; D. B. Fisk & Co., Wabash avenue and Washington street, Chicago, 35 arc plant and 250 incandescent lights,

PATENT METALLIC SHIELDED AND ANTI-INDUCTION WIRE.

Since the general growth of the electric light and railway circuits, telephone service has been more or less hampered by its great enemy, induction. Many attempts, more or less successful, have been tried to overcome this difficulty, and many so-called anti-induction wires have been invented. We illustrate in the accompanying engravings two forms of wire, manufactured under the patents of Henry F. Campbell, of Boston, which are well calculated to overcome induction and to be of valuable service to telephone and telegraph companies, who are willing to pay for first-class installation work. For telephone purposes, as shown in Fig. 1, this wire consists of an ordinary No. 12 galvanized iron wire, insulated either with rubber and saturated braid or with two or three saturated braids, and then spirally wound with a metallic shield consisting of a strip of annealed iron ribbon, and the whole covered over with a strong braiding. But Fig. 2 shows another form of the wire, with a copper shield instead of the iron, which can be supplied if desired. When used for telephone service as a metallic circuit, these wires have shown remarkably good results, and they are attracting a great deal of attention. The metallic shield also acts as a very excellent resistance to abrasion from the limbs of trees or other obstacles, and prevents in a large measure any danger of both sides of the circuit being grounded. The two circuits being in one composite wire, it will also be seen that it effects a great saving in cross arms, insulators and general pole construction. This wire is also manufactured for aerial electric light line wire, the shield in this case acting as a good preventive from abrasion and protecting intact the underlying insulation much better than any cotton or yarn braiding could do. The wire is manufactured by the National Electric Company, of 19 Congress street, Boston, with Mr. Charles E. Jackson, president, and N. T. Greenwood, treasurer, and they have a well equipped factory at 22 Medford street, Boston. Great care is taken with the manufacture of the wire, any desired degree of insulation being attainable, and every reel is thoroughly tested in tanks with delicate galvanometers before shipping.

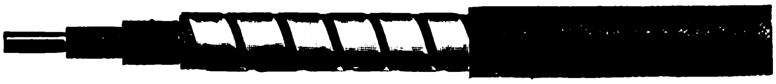


Fig. 1.—Metallic Shielded Anti-Induction Cable.

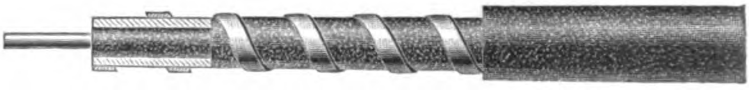

Fig. 2.—Metallic Shielded Anti-Induction Cable.

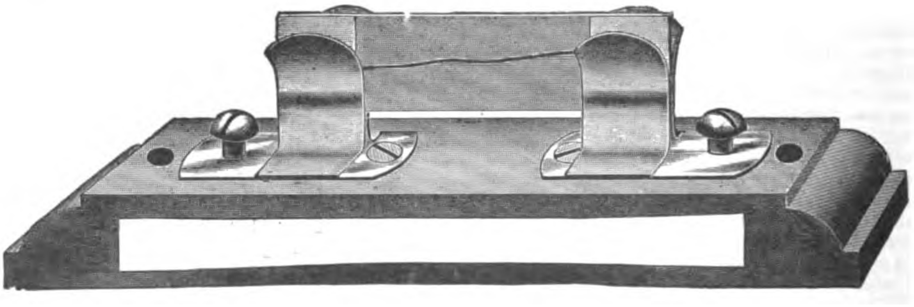
A NEW FUSIBLE STRIP AND HOLDER.

The accompanying illustration shows a convenient form of fusible strip and holder especially designed to protect telegraph, telephone and other instruments from damage by lightning, or heavy dynamic currents. By a new process, the fuse wire is adjusted to blow with any desired current, that in the drawing being for a current of one-half ampere. When a fuse blows, the strip can be removed and a new one substituted with the greatest facility, the inspector carrying a few extra strips in his pocket to replace those destroyed.



The Central Electric Company's Fusible Strip and Holder.

The device is controlled and sold by the Central Electric Company, of Chicago.

Mr. John H. Bowley, formerly assistant to Prof. Morse, and who assisted at the laying of the first Atlantic cable from the American man-of-war "Niagara," died on Sunday, March 1st, at Jersey City.

CAPITAL OFFERED FOR INCANDESCENT LAMP WORKS.

An advertisement appears in our columns this week from a gentleman who represents capitalists desiring to invest in the manufacture of incandescent lamps, and who are ready to put capital in an established business or to start a new concern. The proposition is in every respect one that deserves consideration.

AN INTERESTING LITERARY RELIC.

Mr. G. W. Davenport, the vice-president of the Thomson-Houston International Co., secured recently while in Europe a most interesting relic of which he is very justly proud. It is none other than Michael Faraday's own copy of Franklin's well-known and rare collection of letters and papers on philosophical subjects. It has his book plate on the inside of the front cover, and bears signs of use.

As touching on a late memorable controversy, Mr. Davenport points out that on page 325 Franklin remarks that "Death by electricity would be the easiest of all deaths." It is a little strange that electrocutionists have not hit on this and used it.

THE COLUMBIA SNOW SWEEPER.

In our issue of Feb. 4, we published an illustrated article on the excellent "Columbia" snow sweeper, recently brought out by the Columbia Electric Co., manufacturers of dynamos, motors, &c., St. Paul, Minn. It should be added to the description then given that the car itself was the design of Mr. George Larkin, the chief engineer of the St. Paul City Railway Co., the motors being the design of the Columbia Co., as already stated.

PAISTE ELECTRICAL SPECIALTIES.

A very neat and tastefully printed little catalogue, entitled, "Some Practical Pointers," has been issued by H. T. Paiste, of Philadelphia. The "pointers" refer to several of his specialties, such as switches, cut-outs, sockets, shade holders, etc., all of which are so well known that nothing remains to be said in regard to them, except that they are still enjoying a well earned popularity.

A LARGE CARD ARC MOTOR.

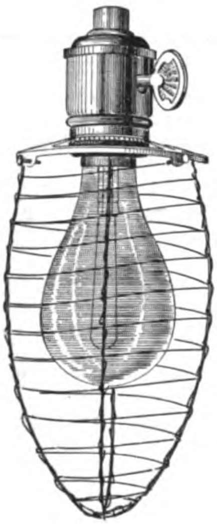
The Card Electric Motor & Dynamo Co., of Cincinnati, have recently shipped one of their new type 6 h. p. arc motors to St. Louis. This machine is probably one of the largest arc motors made.

A NEW DIRECT CABLE OFFICE.

The Direct United States Cable Company has opened a special office at 21½ Spruce street for the purpose of providing a greatly accelerated and more direct service for the numerous patrons of the Atlantic cables in the district familiarly known to New York business men as the "Swamp."

ESTEY'S NEW LAMP GUARD.

Of the many things which recommend the incandescent lamp as an illuminant in theatres, mines, factories, etc., the question of its portability is no small one to consider. But the lamp must be protected, as, should it come in contact with any hard substance, which is liable to happen, it is very easily broken. The accompanying cut shows a wire guard to protect the lamp from this danger. The guard is manufactured by W. S. Estey, 71 Fulton street, this city. This guard is made very strong and fits into any ordinary shade-holder of the necessary diameter.



Estey's New Lamp Guard.

TRANSMISSION ROPE.

The two principal objections to the transmission of power by manilla rope have always been the inability of the rope to stand, for a long time, the effect of moisture, and the internal friction caused by passing over the sheaves.

Both of these faults have been greatly mitigated by the C. W. Hunt Company, of 45 Broadway, in their "Stevedore" transmission rope. This is laid up with tallow and plumbago with the twist of the rope, the tallow making it partially waterproof, and the plumbago acting as a lubricant, and reducing the internal friction. It is claimed to be the only rope that will stand exposure to the weather.

LAVA ELECTRIC INSULATORS.

A substance that is absolutely fire-proof, non-porous, and insoluble, having the rigidity of stone, and the non-conducting properties of dry air, appears certainly to combine in itself every quality desirable in an insulator.

The D. M. Steward Mfg. Company, of Chattanooga, Tenn., seem to have produced such a substance in their lava insulator, which is claimed to possess greater possibilities, and a wider range of application, than any other substance ever used for the purpose. It is equally effective for inside or outside use, underground or in damp places; it can be cut, turned, or molded into any shape required, before being hardened, and the process of hardening does not warp the pieces. Hence it may be made to fit any given place as accurately as brass, often a great desideratum to electricians. No heat, short of the electric arc, has any effect upon it, and, as it is perfectly non-absorbent, it can be used with no fear of damage in cellars, steamy rooms, or where exposed to the fumes of acids, etc.

Holtzer-Cabot Electric Co.—All the right, title and interest of Charles S. Bush Company, and Charles S. Bush, in and to the Providence Construction Co., and its assets, have been sold to the Holtzer-Cabot Electric Co., of Boston, Mass., and all parties are notified that Charles S. Bush Company and Charles S. Bush, will not be liable for any debts contracted by said Providence Construction Company, hereafter. All debts and claims against said Providence Construction Company, may be rendered to the Holtzer-Cabot Electric Company, and will be promptly paid.

WOODBRIDGE & TURNER.

The above enterprising young firm of electrical engineers and street railway contractors have found it necessary to secure larger offices, and have removed to Room 47, the *Times* building, where they will enjoy greater facilities for their growing business.

THE GAYNOR ELECTRIC CO.

A very handsome new factory has been built by the Gaynor Electric Co., of Louisville, Ky. It is of brick 224 feet long, 60 feet wide, and six stories in height. Power is supplied by a 250 h. p. Corliss engine. The company's capacity is increased fourfold, and it is claimed that they will have the largest factory in the world devoted to fire alarm and police signal apparatus.

The company's systems of fire alarm and police signaling are well known and in constant demand. They are now carrying out contracts for San Antonio, Tex.; Lincoln, Neb.; Clinton, Ia., and Louisville, Ky.

THE RAE ELECTRIC RAILWAY SYSTEM.

A very interesting pamphlet has been published by the Detroit Electrical Works on the Rae Electric Railway system which it is introducing with such phenomenal success and rapidity. There is given a very complete description of the system as a whole, and in detail, interspersed with large explanatory cuts; and this part is admirably clear. There is also a neat classification of the various electrical, machanical and economical advantages of using the Rae system. The frontispiece is a fine view of the Detroit Electrical Works on Baltimore and Woodward avenues, Detroit, and the whole is bound up in a handsome cover.

A WORD TO THE WISE STEAM ENGINEER.

A few years ago, says the *Stationary Engineer*, no one dreamed that in so short a time the electric light would become a regular part of the equipment of mills and factories. It was only when the dynamo found its place in the engine room and the incandescent light sparkled in the shops and work rooms that the engineer found anything of special interest to him in the study of electricity. Now he must study it whether he will or no, and though the knowledge he most requires must be of a practical nature, he must have a goodly amount of theoretical or "book" information in order to understand what he is doing.

ST. LOUIS TRADE NOTES.

The East St. Louis Electric Railway is now in successful operation. Thomson-Houston system is used. Eight cars are in use running from the Levee to the National stock yards.

The Columbia Incandescent Lamp Co., having increased their capital stock, have put in new machinery and pumps, increasing their capacity to double their former output. They are now prepared to supply their many customers without delay. Mr. Leonard Schaefer, formerly with the Schaefer Electric Lamp Co., of Cambridgeport, Mass., and the Sawyer-Man Electric Co., has been engaged as superintendent.

The Emerson Electric Manufacturing Co. have brought out a new cross-over for trolley wires, the novel feature of which is that a trolley wheel of any pattern can pass it without flashing. This company are meeting with an excellent trade in all of their late novelties, notably the Bagnall trolley crossing and their spring clip ceiling block.

The Home Novelty Manufacturing Co. have moved into commodious quarters at the northeast corner of Tenth and Walnut streets. This company have undertaken the development of the Unicycle elevated railway system, which was the leading feature of the electrical section of the Exposition last October. A Unicycle motor car of full size is being constructed at their works and the elevated roadway is being erected at the yards of the Unicycle Elevated Railway Co., and all will be ready for a trial in a few weeks.

The American Electrical Manufacturing Co. have taken quarters at Nos. 2,011-2,017 Pine street, and are getting ready for the manufacture of electrical machinery and supplies, and arc and incandescent lamps. Ben. Nahm is president and treasurer; Joseph Wolf, vice-president; and Benj. Dubinsky, formerly with the Heisler Co., is secretary and electrician.

The Electrical Supply Co., of Chicago, continues to make a specialty of fuse wire, and is prepared to supply all sizes in any quantity. The facilities of this company for making accurately calculated fuse wire are unsurpassed and the high quality of the goods is acknowledged on all sides.

THE INSULITE SOCKET.

THE great desideratum in a lamp socket is the utmost simplicity and the fewest parts consistent with the efficient performance of its duty. Bearing this fact in mind, Mr. Thos. G. Roebuck has invented the socket shown in the accompanying illustrations.

The method of wiring the socket is exceedingly simple. For this purpose the cap is slipped over the wire pipe, the set screw B taken out and the insulated screw D loosened, as well as the screw E. One line wire is then inserted into the centre tube C, which is held in contact by the screw D. The other wire is then passed behind the screw E by the shoulder or lip of the contact spring. The socket is held firmly to prevent the wires from twisting while screwing the nozzle home on the line wire pipe; the set screw is then replaced which locks at half a turn of the nozzle.

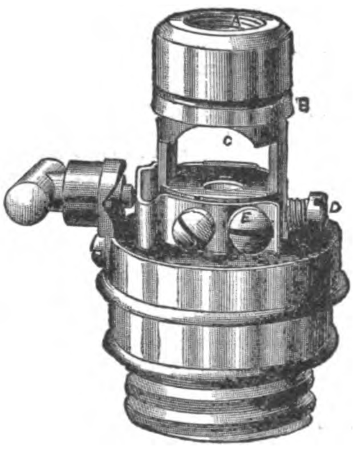


FIG. 1.—THE INSULITE SOCKET.

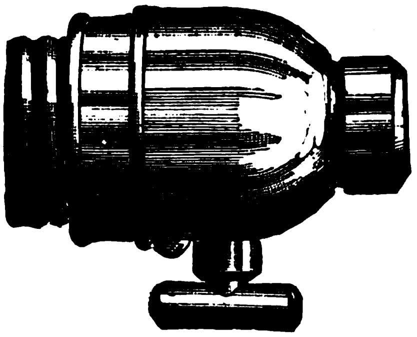

FIG. 2.—THE INSULITE SOCKET.

This simple socket is manufactured by the Insulite Manufacturing Co., of 35 Broadway, of which Mr. Thos. G. Roebuck is the sole selling agent.

COMPLIMENTING THE NEW YORK FIRE TELEGRAPHS.

The Board of Fire Commissioners has had entered upon its minutes, resolutions expressing its high appreciation of the zeal and ability shown by Mr. J. Elliot Smith, its superintendent of telegraph, in meeting promptly and successfully the serious emergency that arose through the destruction of the aerial fire wires and other circuits in the memorable snow storm of January 25.

BURNLEY DRY BATTERIES.

The Central Electric Company are in receipt of a letter from J. Parker & Son, Chicago, in which they state that they have had three Burnley dry batteries in constant use for two years, and that they have been successfully operating six 3 inch bells, which upon a test recently made, were working as satisfactorily as when first put in. They report the largest sales yet recorded on this battery during the month of February.

MR. A. E. HUNT, president of the Pittsburgh Reduction Co., intends giving a lecture on "The Prospects of the Use of Aluminum in Railroad Work," before the Railroad Club, on March 19.

NASSAU ELECTRIC CO.

The Nassau Electric Co. have removed their offices from 19 Park Place to 112 White street, where a full line of their specialties can be seen.

THE D. & H. C. COMPANY'S building at Albany is going to use Grimshaw White Core wire throughout, 100,000 feet being used. The work is being done by the Robinson Electrical Works, of Albany.

WESTERN TRADE NOTES.

THE MOSHER ARC LAMP CO., have produced a carbon that will burn fully twice the length of the ordinary carbon—sixteen to eighteen hours with a single pair of carbons. It will also burn with a very long arc without flaming, which, on incandescent circuits, means a great saving in power.

THE SUNBEAM INCANDESCENT LAMP CO., Manufacturers' Building, Chicago, are just putting in a new 200 h. p. engine and three large dynamos.

MR. J. R. BURDICK, of the H. W. Johns' M'f'g Co., of New York, has been a welcome visitor to Chicago, where he is well known among the electrical fraternity. The famous Vulcabeston insulation for magnet cores, arc lamps, and all purposes where an insulating fibre is required, is in great demand, and all the large electrical manufacturers are using it.

THE BAIN ELECTRIC M'F'G CO., 47 & 49 S. Jefferson street, are now comfortably installed in their new quarters. As heretofore, excellent work will be turned out and with increased facilities, orders for dynamos and motors of the largest size, mining and other special machinery, will be filled with greater promptitude than ever. Electric repairing will also receive the same careful attention. Mr. Bain, the president and engineer of the company, reports business as increasing very rapidly, and the out look is of the most promising and encouraging character.

THE CENTRAL ELECTRIC CO., Chicago, are showing a very unique and effective patented dust protector for contact points in bells, telegraph instruments, etc., which THE ELECTRICAL ENGINEER will fully illustrate when the cuts are prepared.

OKONITE.—For good construction in electrical apparatus where insulation is important, the famous Okonite wires admit no equal, and this is practically demonstrated by the orders for this wire during the dull season, when other things are suffering The Central Electric Company, who are the general Western agents, booked orders last week for more than 2,000,000 feet of varied sizes, the demand being unprecedented, proclaiming "Okonite still king."

THE ELECTRICAL SUPPLY CO., of Chicago, are having an excellent sale for their "Shield Brand" tape, and reports from those using it are highly satisfactory. The tape is prepared to offer insulating qualities similar to those of their well-known moisture-proof line wire, from which it takes its name. The E. S. Co. suggest that a cheap and simple method of discovering the virtues of this tape is to try a little.

MR. W. C. HAGAN, late of the Union Electric Co., at Pittsburgh, spent part of last week among the electrical fraternity in Chicago. He is now in business for himself at Pittsburgh, and has the agency for Simplex wire and a number of good specialties.

CUTTER'S new globeholders for T.-H. lamps, which we illustrated recently, seem to meet a decided want, as the orders for them are growing in number from week to week.

MR. J. H. COOKE has returned recently from a flying trip to Cincinnati and Indianapolis, where he secured some very handsome orders for the "Sunbeams," which in his well-known lamps he has managed to catch and effectually bottle up for distribution to central stations all over the country, which have suffered long enough from the thick clouds attendant heretofore on long lived lamps.

THE ELECTRIC CONSTRUCTION AND REPAIR CO., 205–207 Cana street, Springer Building, Chicago, are now manufacturing in large quantities an improved insulating paper for armature insulation. The paper is a non-conductor of heat, and is covered with a special material of remarkably high insulation, and impervious to moisture. The paper used is a fine quality of bond paper, consequently possessing great strength, and is specially prepared for this work.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XI. MARCH 18, 1891. No. 150.

A THOUGHT IN A LEISURE MOMENT.

BY

Wm S Eaton

WHILE in my laboratory, one day, I had occasion to await the development of a chemical operation then in progress. Casting about for something to occupy an idle moment, my gaze rested upon a small pile of iron turnings, some carbon plates, porous cups and various other odds and ends, and this is what I did.

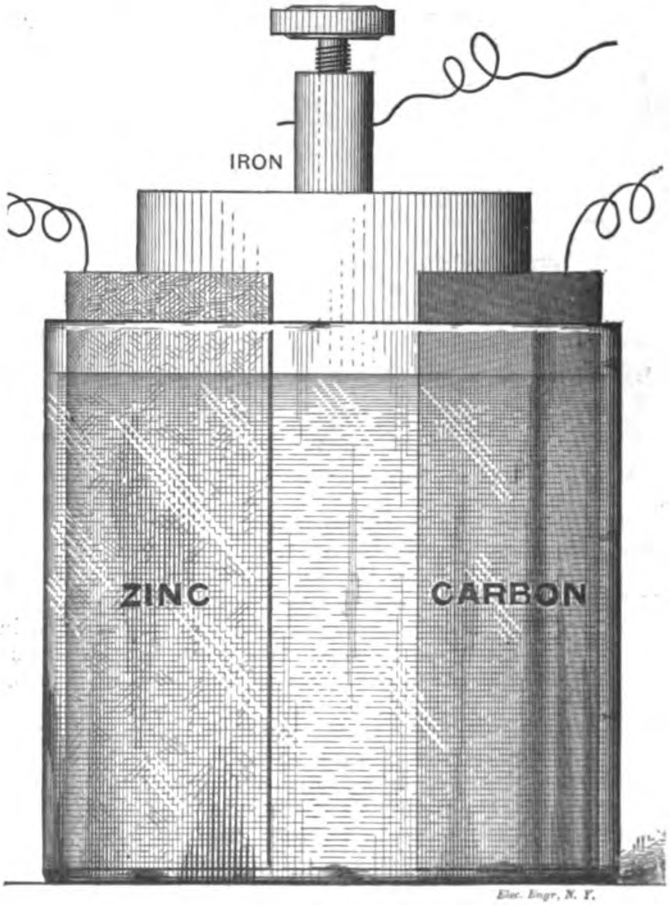
In the centre of a porous cup I placed a bar of ½-inch round wrought iron and rammed about it the iron turnings, to a depth of perhaps one-half an inch; then I dusted in some rouge, then more iron turnings, and so on, until the cup was full of the metal and rouge. By way of explanation, I will say that I did not stop to consider whether, or not, the rouge would be of any service; it was simply close at hand and in it went; nitro-glycerine or hair-oil would, in all probability, have taken the same road, had it been as accessible as the rouge.

My next move was to immerse the porous cup in a weak solution of sulphuric acid and water and pour a little extra into the porous cup for good measure. Next I inserted in the dilute solution outside the porous cup, a plate of carbon and a plate of zinc, the arrangement being shown in the accompanying illustration. I connected the wire from the zinc and iron electrode to a small vibrating bell and "let 'er go." It went; not very strong at first, but better after a little while, and in a few hours stopped.

The iron which had been the negative element of the battery became evidently as oxidizable as the zinc; so I disconnected the zinc and attached the carbon, thus making the iron the positive. This, of course, gave a stronger current than the first. Finally, this ran down and I switched back to the zinc again and got a better result than at the first trial; it seemed to run longer and give a better current. And so I kept changing from zinc to carbon alternately making the iron positive and negative.

For a single fluid battery I must say it did very well, and my recollection of it (this occurred many months ago) is that it ran with the iron as negative element, from Saturday noon until Monday morning. By that time its energy was almost gone; but I got a strong current when I switched the wires again, making the iron once more the positive element. It seemed to me that the iron filings had accumulated considerable electrical energy, and as soon as it was permitted it discharged itself. If such is the case, no doubt there was a large resistance when the zinc-iron elements were connected, which tended to reduce the effectiveness of the battery very materially. When the iron and carbon were connected there seemed to be a powerful rush of current for a short time. I never had the time to make any tests, and after a number of days I dropped it. These facts are as I remember them, and are in the main correct.

Although this experiment was ended almost as soon as begun, yet it made me consider the feasibility of employing, in primary or secondary batteries, some of the material usually accumulated in machine shops and elsewhere, and generally regarded as of no value. I also thought that the effectiveness of storage batteries might be increased, the weight reduced, and the cost lessened, by making up the electrodes of granulated, shaved, or otherwise prepared lead, instead of the plates and grids usually employed in that class of cells. I can see no great difficulty in forming a secondary battery of thin dividing partitions of porous earthenware, ramming in the lead turnings and adding the litharge and minium so as to incorporate the whole thoroughly. It is well known that in storage batteries generally the whole of the lead plate is not doing useful work. In the case of lead shavings, however, we get a greatly increased surface, and simplify the mechanical construction. We also avoid that fruitful source of trouble, buckling in the plates, and I think the weight would be diminished. It is equally true that there may be grave disadvantages attending such construction; yet, as the secondary battery has already proved its usefulness, any idea looking toward an improvement would appear to be worth an investigation.



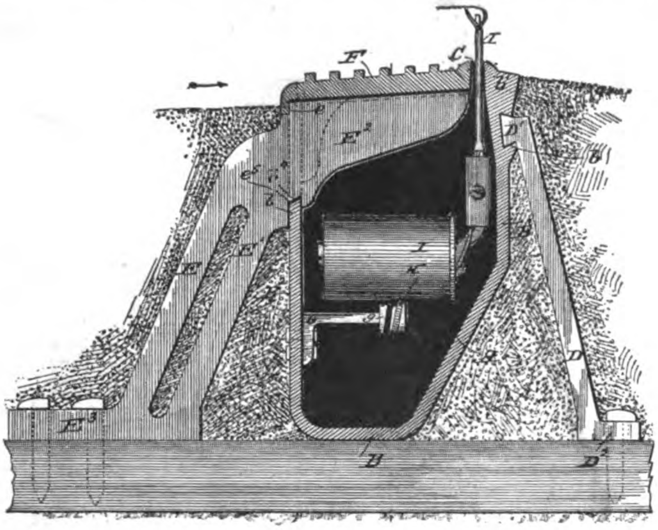
AN EXPERIMENTAL BATTERY.

BLACK'S ELECTRIC RAILWAY CONDUIT.

At the present day, when electric railways are coming into operation so extensively, and when the overhead wire is in many cases looked upon with disfavor by property owners, a practicable underground conduit is of the greatest importance. Mr. Bernard J. Black, of Richmond, Va., with this idea in mind, has designed the conduit shown in section in the accompanying illustration.

As will be seen, the conduit is formed of a series of essentially **U**-shaped metallic yokes B, which are each about four feet long and about one foot deep. The sides of each of the yoke sections extend up above the surface, and form the edges of the slot C. The wall B' of the yoke is provided with a horizontally-disposed dovetail groove *b*, in which are fitted the dovetailed heads D' of a brace-arm D, the lower end of which is anchored, as shown. These arms serve to brace one side of the conduit.

Metal brace-arms E are employed to brace the opposite side of the conduit, and also to serve as supports for the conduit covers. Each of these arms consists of a body portion E', about two inches in width, the upper portion of which extends inwardly, as at E^2, forming brackets for supporting the tops F of the conduit. These brackets extend across the top of the conduit, as shown, and form with the inner ends of the top plates the inner edge of the slot C. By this construction it will be seen that the conduit slot is placed at the inner end of the conduit instead of the centre, as is usually the case, for the purpose of preventing the jarring of passing vehicles from injuring the walls.



BLACK'S ELECTRIC RAILWAY CONDUIT.

Each removable top plate is four feet long, corrugated on its upper face to prevent animals from slipping, and provided with a depending lip which projects over the upper end of the side wall of the yoke, and is seated in a recess *e*, formed in the outer upper edge of the brackets. The upper faces of the bracket portions of the arms are provided with grooves or gutters, which serve to lead the water to one side and prevent it from entering the slot. In placing the conduit in position the concrete or other material forming the street-surface is packed about the conduit flush with the outer upper edge of the top plates, which are rounded, as shown, and form, therefore, practically no obstruction to a vehicle passing in the direction indicated by the arrow.

Vehicles going in the opposite direction, when passing over the slot and coming against the wall, tend to force the end down and make the slot-opening irregular. To securely brace the slot wall, therefore, the plates are provided with depending lugs which rest against the inner face of the yoke, throwing the strain against the conduit wall.

The horizontal brackets, G, support the trolley wire, which is wound about the insulators so as to avoid unnecessary slack. The trolley I is arranged to project laterally and travel on the top of the wire.

This trolley is the joint invention of Mr. Black and Mr. Wilton F. Jenkins, of Richmond, and is detachably connected with the car body, so that, in case of the car leaving the track, the mechanism may not be injured, nor the circuit broken.

THE PROTECTION OF CROSS COUNTRY WIRES.

BY

W. M. Miner

I SHOULD like to say a few words on a subject that is beginning to agitate the minds of some of the electrical engineers of this country, namely:

What shall be done to protect the telegraph and telephone wires from the damaging effects of the snow and sleet storms, such as lately laid low a good share of the wires throughout the country?

I have noticed one or more articles on the subject, which seem to point a little towards a plan I have had in view for some time past, and which may be of interest, as it is, I believe, superior in several respects to any I have heard of. My plan is this:

For all lines alongside and adjacent to the railroads, substitute several cables of a few wires each, supporting these cables by posts of wood, or metal, extending alongside of the track a few feet from the rails, or to timbers and walls, when necessary, eight or more feet apart; cross pieces, for the cables to rest on, being fastened 12 or 18 inches above ground. If preferred, wood or metal troughs or conduits could be secured to these posts, and the cables laid therein. They should be of two or more parts, permitting easy access to the cables.

The advantage of running the cables so near the ground is, the very slight chance there would be of derangement by falling so short a distance to earth. They would work the same even if lying on the ground for a short distance, and for the short time necessary before repairs could be made. If entirely buried in snow and ice, they would continue to work, unless broken, in which case they would be more convenient to handle.

At road crossings and stations the cables could be elevated to poles, high enough to clear all vehicles, etc., or run underground for a short distance.

In using cables composed of a few wires each, repairs would be easier and less expensive to make than if composed of a large number of wires.

Different systems could use different cables, and not be so apt to interfere with each other, as they probably would do if all were bunched in one cable.

At present the available space along most of the railroads is nearly, or quite, taken up by the pole lines, and the poles are nearly all overloaded, making it necessary for some of the lines to follow the highways, go across lots or any way to get there, when the railroad is the shortest and most preferable route.

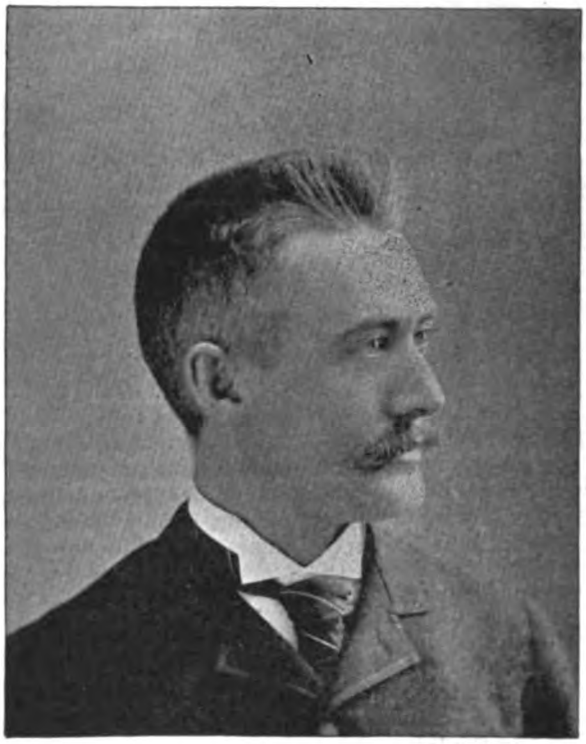
By the proper use of cables these lines could all be placed along the railroads. Of course, lines branching off to small towns off the routes of railroads would be run on poles as now, but few of these towns so situated would require more than one or two wires.

The cost seems to be the greatest drawback to any plan of this kind, but the damage due to a general breakdown of wires, and stoppage of communication, such as has occurred twice or more within the last three or four years, would go far towards paying for such a system as I suggest.

ELECTRICAL ENGINEERS.

FRANK B. RAE.

THE portrait shown on this page is that of Mr. Frank B. Rae, whose electric railway system is being rapidly introduced in different parts of the country. Mr. Rae was born July 25, 1854, at Elmira, N. Y. His father was an English mechanic who had emigrated to this country, and his mother was an American of English parentage. The boy attended the common schools until he was about 12 years old, when his parents removed to Syracuse, N. Y. When fifteen years old he succeeded in securing also about three months in mathematics at the business college, but beyond this he did not enjoy the advantages of regular tuition. At the age of sixteen Rae obtained a position as messenger boy with the Atlantic and Pacific Telegraph Company, at Syracuse. He manifested considerable aptitude for telegraphic work, and after carrying messages for only a month or two, was made batteryman and repairer for the division. Mr. Rae had served perhaps a month or so in this capacity when he was pulled from a thirty-foot pole by a horse car and slightly injured. He has, since that time, taken noble revenge by doing his share in banishing the horse car from our streets. The immediate result of the accident was that it gave him an opportunity to learn practical telegraphy, and upon his recovery he became a railroad operator upon the New York Central Road. In 1872 Mr. Rae returned to the Atlantic and Pacific Company, at Albany, and later was installed at Syracuse as manager. In 1874 he became associated with the Western Union Telegraph Company, in this city, and learned to operate the printing instruments. In 1876, in connection with Mr. C. H. Davis, he published a very useful book of "Diagrams and Connections." This literary effort attracted attention and helped him to obtain a position in San Francisco as quadman. The work that he did there in making the then new system successful, came to the notice of President Orton while that gentleman was visiting the Pacific Coast, and Mr. Rae was appointed electrician for the Western Union Company in that Division. He served in this capacity until 1879 or 1880, when he went into the employ of the Brush Electric Light Company, of San Francisco, and in 1882 he took charge of the Brush plant at San Jose, where he erected one of the first high towers used for city lighting.



Frank B. Rae

In February of 1883, Mr. Rae came East to obtain some patents on devices that he had invented, and had the good fortune to meet Mr. Stephen D. Field, with whom he had already been acquainted in San Francisco. It had been his intention to return to the Coast, but he was induced by Mr. Field to remain in New York. In 1883 he was sent by Mr. Field to Chicago to build the electric railway for the Chicago Exposition of Railway Appliances, and there, with Messrs. Mailloux and Healy, he put in operation the road equipped with the motor "The Judge," which, during the continuance of the exposition, a period of two weeks, carried nearly 27,000 passengers. The road was about one-third of a mile long, and the track was laid on the third rail plan. The average speed maintained was eight miles an hour. This practical piece of work attracted considerable attention, and was followed up by the operation of "The Judge" immediately after at the Louisville Exposition, where Mr. Rae also had charge of the work.

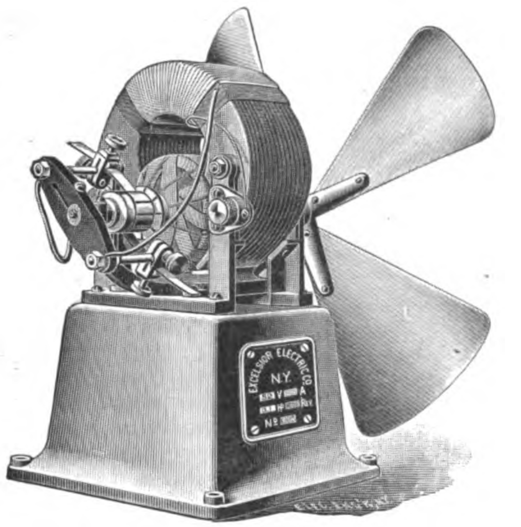
Returning to New York, Mr. Rae was associated with Mr. Field in the perfection of the Field system of stock printing telegraphs, acquired and operated by the Commercial Telegram Company, and Mr. Rae, for some time, was in charge of the large central office at the foot of Broadway. Having put this plant in successful operation, Mr. Rae went into the electrical engineering business with Mr. C. O. Mailloux, and then became electrician, in 1886, for J. H. Bunnell & Co., of this city.

At this time a very tempting offer was made to him in connection with the celebrated Barker-Mitkiewicz concession in China, and he was one of the electrical engineers dispatched by Count Mitkiewicz to the Celestial Empire to bestow on the Chinaman the blessings of telephony and other modern electrical inventions. Mr. Rae proceeded, by way of Suez, to China, and after a stay in that country, which was very brief, owing to the failure to convince the Chinese that they wanted any of the Mitkiewicz blessings, Mr. Rae finished his circumnavigation of the globe by returning home via San Francisco. He had barely landed in this country before he was summoned to Chicago to apply the dynamo to the stock printing telegraph system of the Western Union Company. While there he was employed as an expert to report upon the electric railway system of the Detroit Electrical Works, and did his work in such a satisfactory manner that he was subsequently requested by the Detroit concern to undertake for them the production of a new system. He consented, and in November, 1888, settled in Detroit, assuming charge of the inventing and electrical engineering of the railway department of the Works. Since that time the Rae system has become very widely known, and it is now in use on a large number of roads, in such cities as Cleveland, Galveston, Columbus, O; Portland, Oregon; Colorado Springs, Detroit, Fort Worth, East Reading, Pa.; Joliet, Ill.; while contracts have also been taken for Rochester, South Chicago, Elkhart, Ind.; Adrian, Mich.; Decatur, Ill.; Kansas City, Nashville, Tenn.; Aurora, Ill.; Sault Ste. Marie, Mich.; Springfield, Ill.; Springfield, Mo., and other places. There are a great many individual and distinctive elements in the Rae railway system, and one of the most notable features, to which Mr. Rae has steadfastly adhered, is that of equipping each car with but one motor, the motor being suspended lengthwise the car and driving upon each axle equally by means of bevelled gear, so that there is a material reduction in gearing and in number of wearing parts.

Enough will have been said to show, that in spite of the fact that Mr. Rea is still quite a young man, he has had a very active, eventful and noteworthy career. It may be stated, moreover, that in addition to his motors and railway system, he has invented a number of electrical appliances and devices, among which may be mentioned the Rae "Horn ammeter," illustrated and described in our columns last year.

THE HOCHHAUSEN ALTERNATING FAN MOTOR.

THE wide-spread use of the alternating current has created the demand for its application to the operation of motive power apparatus, and one of the largest fields in this direction, so far, is its application to the driving of fans for ventilating purposes. In keeping, therefore, with the progress of the times, Mr. William Hochhausen, of the Excelsior Electric Company, of this city, has designed the simple little alternating fan motor, illustrated in the accompanying engraving. In this little machine the field-magnet is built up of laminæ of thin sheet iron, and in this way they are fitted for the magnetization by the alternating current, without becoming heated in the least.



THE HOCHHAUSEN ALTERNATING FAN MOTOR.

The magnet, as will be seen, is wound at the top with only 4 ounces of wire. The armature is of the Siemens drum type, and so wound that contiguous wires have but a very small difference of potential between them, thus preventing burn-outs. It is wound in 16 sections and has only 6 ounces of wire on it, being provided with a commutator, and running at 50 volts, for which the motor is designed. The fan revolves at 1,000 revolutions per minute, and the motor is self-starting under full load, consuming no more current than a single incandescent lamp.

The motor itself weighs only 10 pounds, and the base 5 pounds additional, making 15 pounds in all. Although diminutive in size, the mechanical details have been thoroughly worked out, and in addition to its other qualities, it has self-oiling bearings, so that it practically requires attention only at very long intervals. The motor, which we have recently seen in operation, runs without the least sparking.

MAGNETIC ROTATION.

BEFORE the Chemical Society a paper on "Magnetic Rotation" was read by Prof. W. Ostwald, of which the following is an abstract: "The magnetic rotation of organic compounds, according to Perkin, is an additive function of their composition and equal to the sum of the rotations of the components, but this is not the case with the rotation of inorganic compounds, which is usually found greater than that calculated on such an assumption. In the case of hydrogen chloride, for instance, the calculated value is about 2.18, and as a matter of fact the value obtained for hydrogen chloride dissolved in an organic solvent, isoamyl oxide, is 2.24, but when dissolved in water the value found is from 4.05 to 4.42, increasing with the dilution. The author points out that these exceptional values are only obtained in the case of electrolytes, and that they must, therefore, be referred to a fundamental difference existing between the constitution of electrolytes and that of non-conductors. That such a difference exists has been already deduced from other considerations, and has led Arrhenius to the formulation of the theory of electrolytic dissociation. The author claims that the facts established with regard to magnetic rotation are in perfect accordance with this theory, and that any exceptional values in the magnetic rotations of electrolytes are due to the occurrence of electrolytic dissociation."

THE GIBBS DENTAL MALLET.

THE relief obtained by the dentist in the substitution of electric drills and mallets in place of those driven by foot power, as heretofore, has made the former the favorite method, and no dentist who pretends to keep up with the times is now without an electrical outfit. The dental mallet has been the subject of a variety of designs and modifications, but one of the most simple and efficient which has come under our observation is that designed and manufactured by Mr. Wm. E. Gibbs, of this city. This mallet is illustrated in the accompany engraving, and its operation is as follows:

The current entering the lower binding screw, shown in the illustration, passes through a circuit breaker into the coil of an electro-magnet, which slides easily in the hollow handle, thence through a retractile spring connecting the lower end of this magnet with the heavy iron nozzle of the instrument, and traverses the case itself to the other binding screw. The movable mallet being magnetized by the action of the current is drawn down suddenly, and delivers a blow upon the inner end of the chuck which holds the point, at the same time breaking the circuit and allowing the retractile spring to push it back to its original position, when, the circuit being again complete, the blow is repeated.

In order that the circuit shall not be too quickly broken, and also to provide means for regulating the force and rapidity of the blow, the circuit breaker is made of iron and follows the mallet by magnetic attraction until stopped by a shoulder, when a spring takes it back to its former position. The set screw in the head regulates this movement.

THE GIBBS DENTAL MALLET.

Being round and smooth, and without external coils or projections of any kind, the mallet accommodates itself readily to the hand of the operator. The blow is rapid and positive and its force and rapidity may be regulated from the lightest and quickest, to the heaviest and slowest in a moment by means of the adjustment screw between the binding-posts, and further increased or diminished by the amount of hand pressure exerted upon the filling in the tooth.

A push-button of convenient shape lies near the chair, within easy reach of the foot, and the current is supplied by twelve cells of No. 2 Samson battery.

THE MEYLAN-RECHNIEWSKI ELECTRIC ENERGY METER.[1]

BY E. MEYLAN.

As is well known, electric meters may be divided into two great classes, the continuous integrators and the discontinuous integrators, or the automatic reading instruments.

The first are represented at present by the chemical meters, and by what are sometimes termed motor-meters; they are characterized by the fact that the instrument gives at each instant the quantity sought, that is, $\int C\ dt$, or $\int E\ C\ dt$, according to the case, and this either by the accumulation of a metallic deposit, or by the fact that the speed of a movable part is at each instant proportional to the electric energy or to the current. The meters of the second class play the part of an operator, taking off at certain equal intervals the figures of the electric energy or the output, the instrument automatically carrying out the summing up of these variable quantities.

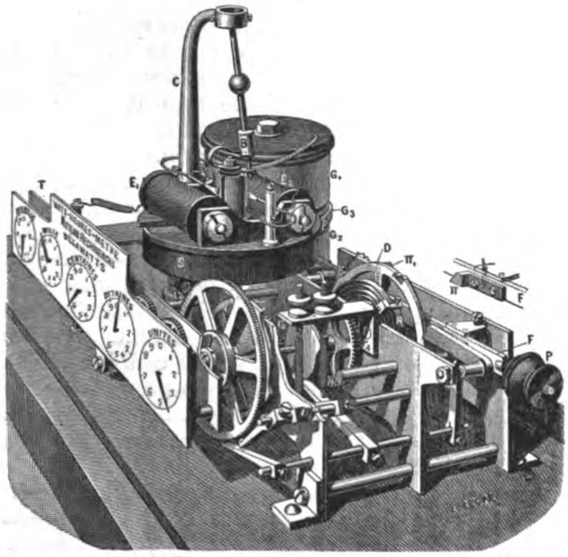


FIG. 1.—THE MEYLAN-RECHNIEWSKI ELECTRIC METER.

The meter constructed by us is of this latter class.

The most important part of the automatic reading meters is the motor, which usually is called upon to furnish, by the constancy of its speed, the equal intervals of time which separate the readings, or rather the equal intervals of time during which the readings take place. In all the meters with which we are acquainted this is done by a clockwork movement wound up by an electric device furnished with a regulator, or by an isochronous motor for discontinuous currents. Now, these arrangements present two distinct disadvantages, the first, and most apparent, being that which results from the electric contacts and the sparking. In spite of all precautions these contacts gradually become dirty and cease to act; moreover, the motive force being essentially intermittent, it is necessary to be absolutely certain that it will act in the position last taken by the moving part each time it returns to a state of rest. The second difficulty is the regulation of this motor; none of the simple regulators employed in clockmaking are efficacious, except within very narrow limits, and it is therefore necessary to make the motor act upon the contacts, in order to make the number and the duration of the electric impulses vary with the variations of the mechanical resistance of the apparatus.

We hope to obtain a better result by using a more robust piece of machinery in the shape of a Gramme motor, which gives no sparks and has no dead point. To adapt it entirely to our needs it is sufficient to add two arrangements—one destined to make the starting certain, the other to regulate the speed.

A motor taking a constant current, supplying the very variable work necessary to take the readings, and giving at the same time the time factor, has, furthermore, the advantage, by no means negligible, of being able to be inserted directly in the shunt circuit, which is needed for the wattmeter, so that in this way one shunt circuit is all that is required.

The Meylan-Rechniewski meter, of which Fig. 1 gives a general view, comprises six principal parts:

1. An electric motor, M, Fig. 2, with permanent current and constant speed.
2. A train of wheels, reducing the speed of the motor and communicating to a final or principal axle, A, Fig. 3, a strictly uniform and continuous rotation, of which the speed is one-third revolution per minute.
3. An electro-dynamic balance—a wattmeter formed by one or two fixed coils, G_1, G_2, traversed by the main current, and a movable coil, G_3, fixed to a beam, F, mounted upon a pivot or upon knife-edges; this balance gives rise, under the action of the main current and the shunt current, to a force proportional to $E\ C$, a force which is balanced by a fixed counteracting force.
4. An elastic cam; this is the part of the apparatus which works the readings of the balance.
5. A gearing arrangement controlled by two detents, communicating to the first moving part of the register, T, the movement of the principal axle during the period of each reading of the balance. The action of the detents is dependent upon the movements of the principal axis of the elastic cam.
6. A integrating register whose various dials show in hecto-watts the consumption of energy in the circuit upon which the meter is connected.

The motor is of a special type. Fig. 2 gives a section and partial elevation, which will serve to make its action clear. It is a disc motor, but one in which the two field magnet poles are on the same side of the armature, that is to say, above the latter; this arrangement gives rise to a real uplifting of the armature core under the action of the magnetic field. This considerably relieves the jewel upon which the pivot rests.

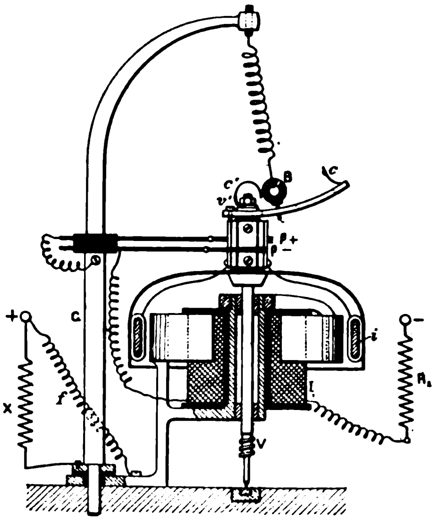

FIG. 2.—THE MEYLAN-RECHNIEWSKI ELECTRIC METER.

The field magnet system comprises two semi-circular pole-pieces, connected together with two square pieces fastened by two bolts, which form the cores of the two electro-magnets, E_1, E_2, Figs. 1 and 2.

The armature is a flat ring of iron, insulated and wound

---

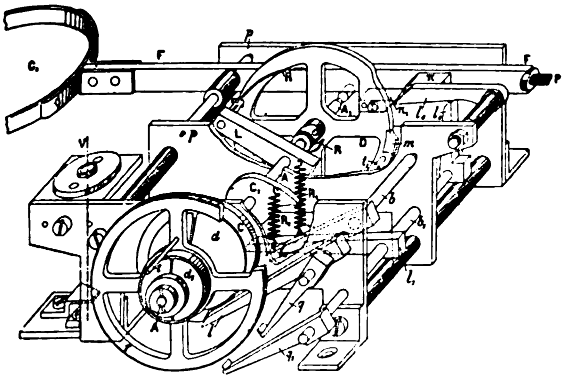
[1] Abstract from the *Bull. de la Soc. Int. des Electr.*

with 3,000 turns of fine wire, forming five or six segments, connected to an ordinary commutator. This armature is carried in an ebonite support, mounted upon the axis, V, whose endless screw works the wheels, $r_1 \ldots r_4$, Figs. 1 and 3.

The field magnet is fixed to the pillar or standard, C, which also carries one of the brushes, $\beta +$. The second brush is held by an insulating support. These brushes are formed of an elastic wire terminated by a flat pinch of silver wire of .15 or .2 millimetre diameter.

The system of regulation consists in periodically shunting the coils of the armature. This result is obtained very simply by connecting one of the commutator plates to the insulated passage which pulls round the conical pendulum which is used as a speed indicator. One of the brushes ($\beta +$) being itself connected to the ball of this pendulum, it will be seen that when the ball, B, touches the contact, c, a part of the shunt current passes outside the armature. For instance, when the plate is under β —, the current goes by way of X, C, B, c, β —, to the field magnet, I, without passing through the armature. On the other hand, when this plate is beneath $\beta +$, the shunt current passes entirely into the armature.

On an average, a decrease of about 50 per cent. of the motor energy is thus produced, which is sufficient, generally speaking, to maintain the speed practically constant within fairly large limits. For a variation of 17.7 per cent. of the volts, the variation of speed was only 2.2 per cent.; in the practical limits of electric lighting, even with a total variation of 10 per cent., the maximum possible error under this head would be only about 1.5 per cent.



. FIG. 3.—THE MEYLAN-RECHNIEWSKI ELECTRIC METER.

The sparking at $c\,\beta$ is absolutely invisible, for it only takes place from the breaking of a circuit traversed by .025 ampere; moreover, the contact is always perfect; and, lastly, the current is never entirely broken, as is the case in the well-known arrangement of Marcel Deprez. On the other hand, it may be considered as practically constant when care has been taken to give the armature a resistance relatively small compared to that of the whole circuit.

The regulator has yet a further purpose, that of assuring a sharp starting of the motor by giving rise to a strong increase of the shunt current while yet the ball has not quitted its central support. This is brought about by a contact, c^1, connected with the axle of the motor, and thence through the body and the wire, f, with the outer extremity of a resistance, X. The other extremity of this resistance being connected to the standard, C, it is seen that so far as concerns the contact between B and c^1, the resistance, X, is shunted, and the shunt circuit then only includes the motor and the rheostat, R_1. The motor therefore rapidly gains its normal speed, and there is never the slightest fear of a misstart.

In the case when it is desired that the meter should act with very variable differences of potential, a *double slotted way* is employed, that is, a passage formed by two parts connected with two plates diametrically opposite. From 90 to 140 volts, the variation of speed is about 2.5 per cent. only, *i. e.*, for a variation of 50 per cent. in the potential.

The electro dynamic balance of the instrument is seen to the left in Fig. 1. The fixed coils, G_1 G_2, are formed by insulated copper strips wound on a central wood core. The two coils are connected so that the actions are added together, and that the force acts upwards. The current is taken from two brass blocks pierced with holes, into which the cables are fixed and tightly screwed by a set screw.

The movable part is formed by a roll of fine wire, G_3 carried upon an ebonite support fixed to the arm by a metal ring rivetted to this latter. This part can be seen in Fig. 3. The current is led to the coil on one side by the pivots, and on the other side by a band of very flexible tinfoil, fixed upon an insulating support near to the axis of suspension. The movable coil is balanced by a counterweight screwed to the end of the arm, F. The engagement of the arm, F, by the elastic cam is brought about by a piece of steel, π, fastened to this arm.

The elastic cam, Fig. 3, comprises the disc, D, carrying the steel cam, π_1, the spiral spring, R, the axle, A_1, and a clutch, L, which connects it to the principal axle, A. The axle, A_1, is carried directly on the end of A between points or on pivots. While the cam, π_1, does not meet the piece π of arm F, the spring, R, is not twisted, and the shaft, A_1, participates in the movement of the axle A. At the moment of contact, on the contrary, the cam is stopped and the spring is twisted through an angle proportional to the pressure that the arm exercises originally upon its acting end. At the moment when the cam raises the arm the reading is finished.

The regulation of the instrument is brought about very simply by assuring the simultaneous freeing of the detent q and the re-engagement of the detent q_1, when the electrodynamic pressure is nil; this regulation is brought about by the position on the shaft of the cam c and the adjustment of the weight, P.

As we have said, the motor is wound in series, and forms part of the fine wire circuit of the wattmeter and a rheostat. The connections of the shunt circuit are therefore those of Fig. 2, of which X would represent a rheostat and R_1, the coil of the wattmeter.

Each meter carries four terminals; the two first to the left, which are insulated, correspond to the positive main, and the positive wire to the lamps; they are connected by the thick wire of the galvanometer. The two others, which together form one connection, serve to fasten the negative main and the negative lamp wire. The shunt circuit is connected on one side to one of the positive terminals, and on the other to one of the negative terminals.

The calibration of the meter is made in such a manner that the first dial of the register indicates a multiple or a decimal part of the electric unit of work, the hecto-watt-hour (1,000 watt-hours).

Thus, for meters of lower capacity (100-110 volts 12 amperes), one division of the first dial corresponds to a deca-watt-hour (10 watt-hours). This calibration is made, for a type once settled upon, by altering in the desired direction the total resistance of the shunt circuit, which is about 2,000 ohms, the speed of all motors being regulated previously so that the rotation of the main axle is made once in three minutes.

Our first model of meter, the ratchet wheel of which has 300 teeth, measures from unity to 70 or 80; furnished with a galvanometer, whose resistance is 0.01 ohm, it forms our type of 12 amperes, and is capable of measuring from one lamp of 8 c. p. (30 watts) up to 40 lamps of 8 c. p., or 20 lamps of 16 c. p.

The principal constants of this type are:

Periodicity of readings............	3′
Constant	1 division = 10 watt-hours
Resistance of shunt circuit..........	2,350 ω
Resistance between terminals........	0.01 ω
Maximum loss of volts..............	0.12 volt
Loss empty (100 volts)...............	4.5 watts
Maximum loss (100 volts 12 amperes)	4.5 + 1.5 = 6 watts
Maximum electro-dynamic couple...	60 gramme-centimetres.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—XVII. (*concl.*)

(*Copyright The Electrical Engineer.*)

BY

Herbert Laws Webb

SIMPLE RULES FOR CONNECTING UP.

In working with portable sets the following simple rules for connecting up will be found of use:

Galvanometer Constant:—Connect one pole of battery to galvanometer, second pole of battery to high resistance, second terminal of galvanometer to second terminal of high resistance; shunt and short circuit key to be bridged across galvanometer circuit.

Insulation:—Connect one pole of battery to galvanometer and the other to earth; join the cable to second terminal of galvanometer; shunt and short circuit key as before.

Condenser Discharge:—Connect "earth" block of condenser, one terminal of galvanometer and one pole of battery together; front block of condenser to lever of discharge key, second terminal of galvanometer to upper contact, and second pole of battery to lower contact of discharge key.

Capacity of Cable:—Connect one pole of battery and one terminal of galvanometer to earth, substitute a cable or lead for condenser at lever of discharge key; other connections the same as in taking discharge of condenser.

Conductor Resistance:—If cable to be measured is single and grounded at distant end, connect as follows: Join one pole of battery to centre of proportional arms of bridge and other pole to earth. Connect cable to extremity of left hand proportional arm, and extremity of adjustable coils to earth. One terminal of galvanometer is connected to extremity of each proportional arm.

If the cable to be measured is double and looped at the distant end, the only difference in the connections will be to join second cable-end and second pole of battery to extremity of adjustable resistance coils, removing the earth connection at this point.

In setting up the instruments the first operation will always be to connect the shunt to the galvanometer, and the short circuit key to the shunt; when this is done the terminals of the short circuit key correspond practically to the terminals of the galvanometer; therefore all galvanometer connections are most conveniently made direct to the short-circuit key.

CARE OF INSTRUMENTS AND CONNECTIONS.

In connecting up instruments either for temporary or permanent use, trim the ends of all wires carefully, tapering the insulation back from the bared portion of the wire, so as to leave no loose shreds of insulation or braiding to make contact with binding posts or other parts of instruments and thus give rise to surface leakage. Always bend wires around binding posts from left to right, so that when the nut is screwed down it will tend to grip the wire firmly and not to loosen it or push it back, as would be the case were the wire bent round from right to left. This point is one of special importance when dealing with stranded wire.

Keep the hard rubber pillars, bases and tops of keys and other instruments thoroughly dry and clean. It is very difficult to prevent dust from lodging on the instruments, as some of the parts are very difficult to get at, but a little careful attention every day with a camel's hair brush and a piece of chamois leather will go a long way toward keeping the instruments in good condition and always looking clean and bright. When not in use the instruments should always be properly covered up. If work is being done every day it is better to dust twice a day—in the morning before beginning work and in the evening before covering up. In any case the morning inspection and dusting should never be omitted.

When the instruments are not in use, all plugs should be kept in position to prevent dust from being deposited in the sockets; dirty plugs and sockets introduce extra resistance. The plugs should be cleaned occasionally with very fine emery paper. The sockets should also be cleaned from time to time in the same manner. This can be done by means of a small wooden plug of a size to fit loosely in the socket; by slitting the plug part of the way up, the edge of a strip of emery paper can be held in the plug and the strip wound round it. With this the sockets in the brass blocks can be thoroughly cleaned. If the plugs and sockets are kept clean there will be no danger of introducing extra resistance from bad contacts and accurate measurements can be depended upon. The platinum contacts of the keys should be cleaned occasionally by rubbing with a piece of ordinary unglazed writing paper, or, if they have become very dirty, with very fine emery paper. Keys with rubbing contacts will seldom need this attention, as the contacts are kept clean by the friction of the two surfaces. When ordering keys it should be insisted that all the fixed parts of brass be secured to the hard rubber pillars by means of steady pins. If the steady pins are omitted, the levers, contact plates and bridges will soon work loose and shift round—a very annoying and troublesome defect.

The bases of keys and other light instruments are generally drilled at the corners so that they may be screwed down to the table. A better plan, which will insure more thorough insulation, can be adopted if the instruments are to be used permanently in one place. This is to have the bases made solid, *i. e.*, without holes, and to stick the keys to the table with Chatterton's compound, or some similar elastic glue. In damp places the insulation of the instruments can be improved by covering the table with a sheet of gutta percha before setting up the instruments.

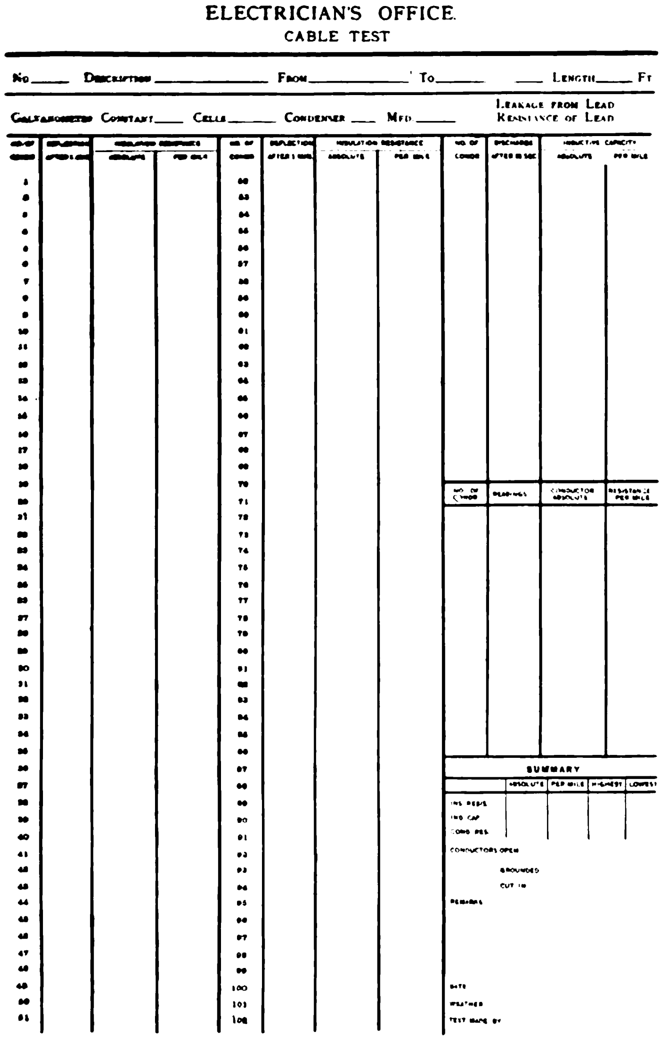
RECORDS AND REPORTS OF TESTS.

In keeping records and making reports of tests for future reference, or for the information of others, care should be taken to make the information recorded as full as possible, so that all the data that can possibly be required at any future time may be always accessible. In making reports or entering up records of tests there can be no greater error on the part of the observer than to imagine, because certain data are quite well known to him, that there is no necessity to write them down, as he can always remember all about the matter himself. The object of keeping records and making reports is to furnish other persons with full information on the subject; and the records should be so written up that anyone needing to refer to them five, ten or twenty years after, might be able to readily ascertain the whole history of any cable tested, the conditions under which the test was made, and, if he found it desirable so to do, to check the figures and work out the test for himself.

This can only be made possible by inserting in the records all the details of the construction of the cable, such as size of the conductor, style and thickness or weight per mile of insulation, length of cable, etc., and all the figures referring to the test, such as battery power, resistance and shunt used in taking the galvanometer constant, battery power and shunt used in taking insulation test, leakage from lead, resistance and capacity of lead, capacity of condenser and battery power used in taking discharge from standard condenser. The state of the weather and the temperature should also be noted. When these data are all correctly given, a record of a test has permanent value; when they are omitted or given incorrectly, or in such form as to leave room for doubt as to their exact meaning, the record is almost useless for reference, as little dependence can be placed on a "bald and unconvincing tale" in which results only are given.

Another bad practice in writing up records, almost as reprehensible as that of suppressing information, is that of using abbreviations which are understood only by the inventor or abbreviator. All remarks should be written in plain English, and, where abbreviations are used, they should be only such as are customary and "to be understanded of the common people."

In making a report of a new type of cable it is necessary to enter more into detail than in reporting the test of a cable of well-known and frequently used description, particularly if the new cable is supposed to embody any special advances over previous methods, or if valuable advantages are expected to be derived from its adoption. In such a case it is necessary, besides giving a full report of the electrical tests, to make a detailed description of the mechanical construction of the cable, specifying the number, size and weight per mile of conductors; the nature of the insulating material, and the thickness and weight per mile on each conductor; the method of laying-up the conductors; style and amount of material used for outer protection; weight of complete cable per foot or mile, etc. Reports of this kind will, of course, vary in each case, but the point is that it should always be borne in mind that an electrical test alone does not give sufficient data on which to base an opinion of the merits of a new type of cable.



ELECTRICIAN'S OFFICE.
CABLE TEST

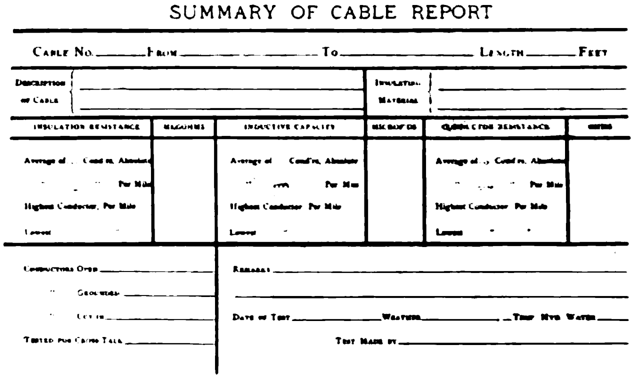
No.____ Description ____________ From ____________ To ______ ____ Length ____ Ft.
Galvanometer Constant ____ Cells ____ Condenser ____ Mfd. ____ Leakage from Lead / Resistance of Lead

FIG. 37.

When the report deals only with a test on a cable of standard type, there is no necessity to enter all the mechanical details; it will be well to consider, however, the entries which should always be made, and these will serve as a guide for drafting forms for test blanks and record books.

Topographical Data:—Name or number of cable, location of terminals, and length of cable.

Mechanical Data:—Type of cable, manufacturer's name, number of conductors, size of conductors, thickness of insulation, description of insulating material, description and thickness or weight of outer covering. In some cases the name of the cable, if some conventional trade name is used, will be sufficient to indicate by whom the cable is manufactured, and also its general mechanical construction, as such cables are generally made to a standard specification which is only departed from when improved methods of manufacture render it necessary or advisable to amend the specifications.



SUMMARY OF CABLE REPORT

Cable No. ______ From ____________ To ____________ Length ______ Feet
Description of Cable ____________ Insulating Material ____________
Conductors Open ______ Grounded ______ Cut in ______ Tested for Cross Talk ______
Remarks ____________
Date of Test ______ Weather ______ Temp. Hyd. Water ______
Test Made by ____________

Insulation Resistance
Megohms
Inductive Capacity
Microfds.
Conductor Resistance
Ohms
Average of Cond'rs, Absolute
Per Mile
Highest Conductor, Per Mile
Lowest

FIG. 38.

Electrical Data:—Galvanometer constant, stating battery power, shunt and resistance used and deflection obtained. Leakage from lead taken with full battery. Discharge from lead taken with same number of cells as used in capacity test. Resistance of lead. Discharge from standard condenser, stating battery power, capacity of condenser used and deflection obtained. Deflection for insulation on each conductor and insulation resistance, absolute and per mile. Discharge deflection on each conductor and capacity, absolute and per mile. Resistance of each conductor (or loop) with lead, absolute resistance (lead deducted) and resistance per mile.

General Remarks:—Make note of any conductors open or grounded, number of working wires in cable, or anything in the condition of the cable likely to affect the test. Note the condition of the weather and the temperature of the air, and of the hydrant water if the cable is laid underground or of the tank water if the test is made in the factory. Note the date of the test and name of the person who makes it.

It is useful in the case of a cable containing a number of conductors to add a summary giving the average insulation resistance, capacity and conductor resistance of all the wires tested, and the highest and lowest results in each test. This shows at a glance the general condition of the cable.

In preparing a test sheet for filling in the above information, the heading should contain the spaces for the description of the cable, route, location of terminals, length, mechanical details, etc. Immediately below should be the spaces for galvanometer constant and condenser discharge, and particulars of the lead, *i. e.*, its leakage discharge and resistance. The rest of the sheet should be ruled in vertical columns for insulation resistance, inductive capacity and conductor resistance, a column being made for the conductor number, another for the deflection or reading, a third for the absolute, and a fourth for the per mile. At the bottom of the sheet spaces may be ruled for the summary of average results, general remarks, date and weather, and name of observer.

The accompanying forms show, first, a full test-sheet for recording the test on a telephone cable, containing fifty-one pairs of wires, that being the type of cable generally adopted by telephone companies using underground systems; and second, a summary of the test for furnishing a report to the executive department, on the general condition of a cable. (Figs. 37 and 38.)

In the heading of the test-sheet are left spaces for the number, description, route and length of the cable. Below this are entered the galvanometer constant and discharge from standard condenser, spaces being left to fill in the number of cells, high resistance and shunt used and the capacity of condenser and battery power employed in taking the discharge. The particulars of the lead are noted here, and in cases where a long lead is used, it would be useful to enter the discharge from the lead before connecting on the cable for capacity test. The rest of the sheet explains itself, the vertical columns being ruled for entering the readings in each test and the results, absolute and per mile, in megohms, microfarads and ohms. The summary at the bottom of the sheet is a useful addition, as it shows at a glance the general condition of the cable. The figures entered in the summary are transferred to the second form, "summary of cable report," when it is necessary to report a test to some department other than that in which the full records are kept. The permanent record book is ruled in an almost precisely similar manner to the test-sheet used for noting down the observations at the time the test is made, with the exception that the summary is transferred to the heading.

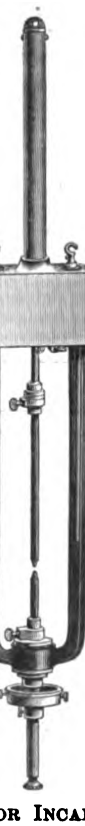
In designing test-sheets for use in cable factories, or for testing single wires, such as electric light cables or overhead wires, the sheet can, of course, be made much smaller, but it will be found a good plan to use a heading, similar to that described above, giving all the details of the cable itself and of the constants used in working out the test, otherwise the records will be incomplete and unsatisfactory.

THE NEW WARD ARC LAMP FOR INCANDESCENT CIRCUITS.

One of the most pronounced features of the present practice of electric lighting and one which is constantly gaining in popularity is the placing of arc lamps on incandescent circuits. While this method of operation was at one time looked upon with distrust, it may be safely said that this was only brought about by the inferiority of the arc lamps at that time available. With the improved construction which has since been brought out, the system has gained rapidly and no better example can be given, not only of its popularity, but also of its economy, than by citing the fact that the Edison Illuminating Company, of Brooklyn, has installed about 625 arc lamps on its incandescent circuits. The lamp here employed is the well-known Ward arc lamp, and a glance at the conditions to be fulfilled and the advantages of operating such lamps is well worthy of consideration.

To begin with, the operation of an arc lamp upon incandescent circuits obviates the necessity of introducing a high tension wire into a building, while on the other hand it offers the great convenience of allowing the arc lamp to be connected to the same circuit as the incandescent lamps for which the building is already wired. This makes the lamp equally well adapted for interior as well as exterior lighting. Again, if we consider the fact that arc lamps placed in circuit with motors are subject to fluctuation, due to the varying work of the motors, the advantages of arc lamps on incandescent circuits are obvious. Although it has been claimed that such an arrangement acts disadvantageously on incandescent lamps, causing unsteadiness and larger breakage, these faults have not been found to exist in installations where the lamp is one that is properly designed, such as that shown in the accompanying illustration. It is evident that both the arc and incandescent lamps, being connected to a constant potential circuit, are practically independent of each other, and that if the potential be maintained constant from the station, there is no good reason why the incandescent lamps should suffer.

The economy of placing arc lamps on incandescent circuits must also be obvious. In the Ward lamp, for instance, which takes 55 volts, two are placed in series across a 110 volt circuit and consume but 8 amperes. These two lamps give an effective illumination equal to 1,600 c. p. each, or 3,200 c. p. The same current, 8 amperes, passing through incandescent lamps would be able to run only 16 lamps of 16 c. p. each, equal to 256 c. p. of illumination. The enormous superiority of the arc light in economy is obvious, and this has been well recognized, especially by the owners of isolated plants. We may mention as instances of this that in the Worthington Pump Works in Brooklyn, alone, 72 of the Ward lamps are in daily operation; 44 at the Grand Central Depot, New York; 56 in the Manhattan Real Estate Association; and 38 in the De la Vergne Manufacturing Company's Works.



Ward Arc Lamp For Incandescent Circuits.

It is obvious that where it is not desired to run two lamps in series, a suitable resistance can be inserted as a compensator. In the new Ward lamp, which is manufactured by the Electric Construction and Supply Co., of this city, a combination feed is employed which operates so that any variation in the current, passing through either of the coils of the lamp, immediately acts to put the controlling mechanism in operation. The lamp is provided with an automatic cut-out, which controls the current perfectly under all conditions, and with a separate switch which renders the trimming of the lamps easy.

New York City.—The Board of Fire Underwriters has extended its thanks to Mr. J. Elliott Smith, the superintendent of the Fire Alarm Telegraphs, and his assistants, for the speedy manner in which the fire alarm telegraph system was restored after the storm of January 25, when so many lines went down all over the city. The Board asks for all the fire telegraph wires to be put underground as soon as possible.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, MARCH 18, 1891. No. 150.

By observation and experiment alone can the mind of man arrive at the knowledge of the laws which rule the universe.—Bacon.

ALTERNATING CURRENTS OF VERY HIGH FREQUENCY.

THE admirable address of Professor Crookes before the London Institution of Electrical Engineers, in which he gave a résumé of his long-continued researches on matter in the so-called "radiant" state, constituted not only a valuable contribution to our knowledge on this subject, but deserves additional recognition from the fact that it has served to call out the work of other explorers in this field, who had thus far remained silent on the subject.

It will be remembered that Prof. Crookes cited as a novel experiment the fact that he had constructed vacuum tubes in which the electrodes were entirely on the exterior, and with which he was nevertheless able to demonstrate the peculiar phenomena noticed in such tubes. It would seem, as above stated, that others have also observed these phenomena, among them being Mr. Nikola Tesla, whose work in this connection requires more than passing notice.

Mr. Tesla, recognizing the fact that the intensity of the effects produced in vacuum tubes, might be considerably enhanced by increasing the frequency of the alternations in the electric impulses, set about the construction of apparatus for this purpose, and after considerable experimenting, succeeded in obtaining a machine giving no less than 30,000 alternations per second. With such a machine at his command, Mr. Tesla experimented on Geissler tubes, and, among other remarkable effects obtained, is one in which an incandescent lamp approached to an induction coil through which currents of such high frequency are passing, lights up and is perceptibly heated. Again, by grasping the lamp by the glass bulb and bringing the metallic terminals near to, or in contact with, a conductor connected to the coil, the carbon is brought to bright incandescence and the glass is rapidly heated.

One of the most remarkable facts in connection with this subject, pointed out by Mr. Tesla, and which has been confirmed by the experiments of Dr. Tatum, with a machine placed at his disposal by Prof. Thomson, as detailed in our last issue, is, that with a 100 volt 10 c. p. lamp, the operator is able to stand without great discomfort a current sufficient to light the lamp brilliantly, thus showing that currents of high frequency are not as dangerous to human life as those ordinarily employed in practice.

Again, Mr. Tesla cites the remarkable effects of placing a condenser in connection with a machine of such high frequency of alternation as he employs. Thus, two bare copper wires of about 20 feet in length and two millimetres in diameter were connected to the terminals of the machine at one end and to a condenser on the other. The electromotive force at the terminals of the condensers was about 120 volts, while at the machine, a distance of only 20 feet, the voltage was only 65.

To explain this phenomenon Mr. Tesla looked for a case of resonance but he finally proved that the capacity which gave the highest E. M. F. corresponded most nearly to that which just counteracted the self-induction with the existing frequency, and any increase or diminution was followed by a fall in the E. M. F. Mr. Tesla concludes from his experience that the condenser may become a very efficient apparatus and capable of transforming considerable amounts of energy. These experiments it will be noted are closely allied to the phenomena observed in connection with the Ferranti mains operated from the Deptford station in London.

Regarding the heating of condensers which takes place when subjected to considerable current of high frequency, Mr. Tesla considers this to be due to three distinct causes: First, leakage or conduction; second, imperfect elasticity in the dielectric; and, third, surging of the charges in the conductor. In utilizing this condenser principle, Mr. Tesla has made incandescent lamps, the end of the filaments being completely sealed in glass, but attached to interior condenser coatings, so that all the energy required must be transferred across the glass with a condenser surface of no more than a few centimetres square. With alternations as high as 15,000 per second it is easy to bring the filaments to incandescence. Unfortunately, however, Mr. Tesla finds that after awhile the glass is perforated by the intense action and the vacuum is thus impaired, but the higher the frequency the longer the lamp holds out. Mr. Tesla points out also that condensers capable of standing a great difference of potential require a dielectric which will involve no losses, and the only perfect one in this respect would be a condenser in which the gas is under pressure; and he has experimented with such a condenser. His experience shows, however, that they are attended with many practical difficulties. In order to make condensers practically useful, higher frequencies would be required, though such a plan, Mr. Tesla points out, has many disadvantages, among them being the fact that they would not be suitable for the operation of motors.

Now that attention has been called to the variety of phenomena which may be observed with currents of such high frequency, the construction of machines for generating them becomes of considerable interest to the electrical engineer. Our readers will, therefore, be interested in the description appearing in another column of several types of machines constructed by Mr. Tesla giving alternations up to as high as 30,000 per second. While, on the surface, the construction of a machine to give a very high number of alternations per second seems a simple enough matter, its carrying out in practice will, upon further examination, be found to involve difficulties of no mean order. Aside from the electrical and magnetic obstacles, which are in themselves sufficient to try the patience of even the most sanguine, the mechanical construction of such a machine, necessarily revolved at enormous speeds, introduces difficulties of a very serious nature.

Mr. Tesla in this issue also continues the discussion on the effect upon arc lamps and arc lamp mechanism of undulating currents, a subject which Prof. Thomson has taken up in his recent communication in our columns.

THE NEW CIRCUIT COURT OF APPEALS.

The act to establish a Circuit Court of Appeals, which was approved by the President on March 3, provides for a Court of Appeals of three Judges, in each judicial circuit, of which two are to constitute a quorum. The Chief Justice of the Supreme Court, the associate justice assigned to each circuit, and the district judges, are competent to sit in the respective circuits. Any judge before whom a case has been originally heard in the district or circuit court is prohibited from sitting at the hearing of the case on appeal. The term of the new court commences the second Monday in January, in the cities of Boston, New York, Philadelphia, Richmond, New Orleans, Cincinnati, Chicago, St. Louis and San Francisco. Appeals from existing district or circuit courts to the supreme court may be taken in cases involving the construction of the Constitution, but in admiralty and patent cases the decision of the circuit court of appeals is final. The circuit courts may, however, certify to the supreme court "any question or proposition of law concerning which it desires the instruction of that court for its proper decision." In any of the classes of cases made final, which includes patent cases, "it shall be competent for the supreme court to require, by *certiorari* or otherwise, any such case to be certified to the supreme court for its review or determination."

Patentees of inventions, owners of patents, and inventors have, we think, abundant cause to congratulate themselves upon the passage of this much needed act. Heretofore, more especially during the past ten years, many of the decisions of the supreme court in patent cases, have been, to say the least, far from satisfactory. Not only have appealed cases been compelled to wait many years for hearing and final determination, but the crowded state of the calendars has rendered it wholly impossible for the justices to bestow upon intricate and complicated questions anything like the amount of consideration necessary to the proper disposition of them, and in fact, many of the opinions themselves are quite sufficient to show that the technicalities of the case could have been but imperfectly understood. The assertion which has often been made, that in cases difficult of comprehension the decision of the supreme court has uniformly been adverse to the patent, does not appear to be altogether without reason. The establishment of the new court will not only insure a much more speedy determination of appealed cases, but a far more careful consideration of the points at issue than has heretofore been possible, and we feel well assured that interests of honest litigants, as well as of abstract justice, cannot but be greatly promoted. Such a result must necessarily have a most favorable effect upon the value of patent property, as well as upon the progress of invention and the development of the electrical arts.

ELECTRIC RAILROADING AND RAILS.

It is perhaps to be regretted that the discussion on Mr. O. T. Crosby's admirable paper read before the Institute did not enter more deeply into the electrical conditions relating to high speed railways, but the direction in which it tended gives unmistakable proof of the fact that electrical engineers are thoroughly aroused to the important question of track construction as an element in the successful operation of electric railways of all kinds. Mr. Crosby pointed out, and Dr. Dudley substantiated in the most thorough manner, the fact, that, for successful high speed railroading, the track must be of such a nature as to offer a minimum resistance to the passage of the train independent of the questions of safety, which would be involved in an inferior track construction at such high speeds. The unreliability of the text-book formulae respecting the coefficients of traction, especially for street railway work, are, we are glad to say, now thoroughly recognized, so that no electrical engineer engaged in this kind of work need be led astray by them any longer. What was pointed out so forcibly as desirable for high speed service is equally applicable to our ordinary electric street car service, and street railway managers are, we believe, already alive to the fact that continuous and successful operation with a minimum of repair can only be secured with a good track.

Backsheesh Again.

The State of New Jersey, under Governor Abbett's administration, seems to be aiming to take the lead in legislation directed to the squeezing of corporations. The taxation bill brought forward at Trenton recently, threatened all New Jersey corporations with an appalling inroad to their treasuries, and now comes assembly bill 348, introduced March 2, by Mr. Trefz, which, if passed, will have serious consequences to all electrical companies in the State. In the 7th and 8th sections authority is conferred upon a State Board to contract with any person or corporation for the construction of subways, and provision is made *that such construction is to be paid for from the rentals received from those using them.* Here is "richness" that might make even a Tammany politician's eyes green with envy. We are informed that the telephone, telegraph and electric lighting companies are taking prompt measures to oppose the bill. Any electric companies in New Jersey that have not already done so will do well to fall into line at once.

EXPERIMENTS WITH ALTERNATING CURRENTS OF HIGH FREQUENCY.

BY

Nikola Tesla

In The Electrical Engineer issue of 11th inst., I find a note of Prof. Elihu Thomson relating to some of my experiments with alternating currents of very high frequency.

Prof. Thomson calls the attention of your readers to the interesting fact that he has performed some experiments in the same line. I was not quite unprepared to hear this, as a letter from him has appeared in the *Electrician* a few months ago, in which he mentions a small alternate current machine which was capable of giving, I believe, 5,000 alternations per second, from which letter it likewise appears that his investigations on that subject are of a more recent date.

Prof. Thomson describes an experiment with a bulb enclosing a carbon filament which was brought to incandescence by the bombardment of the molecules of the residual gas when the bulb was immersed in water "rendered slightly conducting by salt dissolved therein," (?) and a potential of 1,000 volts alternating 5,000 time a second applied to the carbon strip. Similar experiments have, of course, been performed by many experimenters, the only distinctive feature in Prof. Thomson's experiment being the comparatively high rate of alternation. These experiments can also be performed with a steady difference of potential between the water and the carbon strip in which case, of course, conduction through the glass takes place, the difference of potential required being in proportion to the thickness of the glass. With 5,00 alternations per second, conduction still takes place, but the condenser effect is preponderating. It goes, of course, without saying that the heating of the glass in such a case is principally due to the bombardment of the molecules, partly also to leakage or conduction, but it is an undeniable fact that the glass may also be heated merely by the molecular displacement. The interesting feature in my experiments was that a lamp would light up when brought near to an induction coil, and that it could be held in the hand and the filament brought to incandescence.

Experiments of the kind described I have followed up for a long time with some practical objects in view. In connection with the experiment described by Prof. Thomson, it may be of interest to mention a very pretty phenomenon which may be observed with an incandescent lamp If a lamp be immersed in water as far as practicable and the filament and the vessel connected to the terminals of an induction coil operated from a machine such as I have used in my experiments, one may see the dull red filament surrounded by a very luminous globe around which there is a less luminous space. The effect is probably due to reflection, as the globe is sharply defined, but may also be due to a "dark space;" at any rate it is so pretty that it must be seen to be appreciated.

Prof. Thomson has misunderstood my statement about the limit of audition. I was perfectly well aware of the fact that opinions differ widely on this point. Nor was I surprised to find that arcs of about 10,000 impulses per second, emit a sound. My statement "the *curious* point is," etc. was only made in deference to an opinion expressed by Sir William Thomson. There was absolutely no stress laid on the precise number. The popular belief was that something like 10,000 to 20,000 per second, or 20,000 to 40,000, at the utmost was the limit. For my argument this was immaterial. I contended that sounds of an incomparably greater number, that is, many times even the highest number, could be heard if they could be produced with sufficient power. My statement was only speculative, but I have devised means which I think may allow me to learn something definite on that point. I have not the least doubt that it is simply a question of power. A very short arc may be silent with 10,000 per second, but just as soon as it is lengthened it begins to emit a sound. The vibrations are the same in number, but more powerful.

Prof. Thomson states that I am taking as the limit of "audition sounds from 5,000 to 10,000 complete waves per second." There is nothing in my statements from which the above could be inferred, but Prof. Thomson has perhaps not thought that there are two sound vibrations for each complete current wave, the former being independent of the direction of the current.

I am glad to learn that Prof. Thomson agrees with me as to the causes of the persistence of the arc. Theoretical considerations considerable time since have led me to the belief that arcs produced by currents of such high frequency would possess this and other desirable features. One of my objects in this direction has been to produce a practicable small arc. With these currents, for many reasons, much smaller arcs are practicable.

The interpretation by Prof. Thomson of my statements about the arc system leads me *now*, he will pardon me for saying so, to believe that what is most essential to the success of an arc system is a good management. Nevertheless I feel confident of the correctness of the views expressed. The conditions in practice are so manifold that it is impossible for any type of machine to prove best in all the different conditions.

In one case, where the circuit is many miles long, it is desirable to employ the most efficient machine with the least internal resistance; in another case such a machine would not be the best to employ. It will certainly be admitted that a machine of any type must have a greater resistance if intended to operate arc lights than if it is designed to supply incandescent lamps in series. When arc lights are operated and the resistance is small, the lamps are unsteady, unless a type of lamp is employed in which the carbons are separated by a mechanism which has no further influence upon the feed, the feeding being effected by an independent mechanism; but even in this case the resistance must be considerably greater to allow a quiet working of the lamps. Now, if the machine be such as to yield a steady current, there is no way of attaining the desired result except by putting the required resistance somewhere either inside or outside of the machine. The latter is hardly practicable, for the customer may stand a hot machine, but he looks with suspicion upon a hot resistance box. A good automatic regulator of course improves the machine and allows us to reduce the internal resistance to some extent, but not as far as would be desirable. Now, since resistance is loss, we can advantageously replace resistance in the machine by an equivalent impedence. But to produce a great impedence with small ohmic resistance, it is necessary to have self-induction and variation of current, and the greater the self-induction and the rate of change of the current, the greater the impedence may be made, while the ohmic resistance may be very small. It may also be remarked that the impedence of the circuit external to the machine is likewise increased. As regards the increase in ohmic resistance in consequence of the variation of the current, the same is, in the commercial machines now in use, very small. Clearly then a great advantage is gained by providing self induction in the machine circuit and undulating the current, for it is possible to replace a machine which has a resistance of, say, 16 ohms by one which has no more than 2 or 3 ohms, and the lights will work even steadier. It seems to me therefore, that my saying that self-induction is essential to the commercial success of an arc system is justified. What is still more important, such a machine will cost considerably less. But to realize fully the benefits, it is preferable to employ an alternate current machine, as in this case a greater rate of change in the current is obtainable. Just what the ratio of resistance to impedence is in the Brush and Thomson machines is nowhere stated, but I think that it is smaller in the Brush machine, judging from its construction.

As regards the better working of clutch lamps with undulating currents, there is, according to my experience, not the least doubt about it. I have proved it on a variety of lamps to the complete satisfaction not only of myself, but of many others. To see the improvement in the feed due to the jar of the clutch at its best it is desirable to employ a lamp in which an independent clutch mechanism effects the feed, and the release of the rod is independent of the up and down movement. In such a lamp the clutch has a small inertia and is very sensitive to vibration, whereas, if the feed is effected by the up and down movement of the lever carrying the rod, the inertia of the system is so great that it is not affected as much by vibration, especially if, as in many cases, a dash pot is employed. During the year 1885 I perfected such a lamp which was calculated to be operated with undulating currents. With about 1,500 to 1,800 current impulses per minute the feed of this lamp is such that absolutely no movement of the rod can be observed, even if the arc be magnified fifty-fold by means of a lens; whereas, if a steady current is employed, the lamp feeds by small steps. I have, however, demonstrated this feature on other types of lamps, among them being a derived circuit lamp such as Prof. Thomson refers to. I conceived the idea of such a lamp early in 1884, and when my first company was started, this was the first lamp I perfected. It was not until the lamp was ready for manufacture that, on receiving copies of applications from the Patent Office, I learned for the first time, not having had any knowledge of the state of the art in America, that Prof. Thomson had anticipated me and had obtained many patents on this principle, which, of course, greatly disappointed and embarrassed me at that time. I observed the improvement of the feed with undulating currents on that lamp, but I recognized the advantage of providing a light and independent clutch unhampered in its movements. Circumstances did not allow me to carry out at that time some designs of machines I had in mind, and with the existing machines the lamp has worked at a great disadvantage. I cannot agree with Prof. Thomson that small vibrations would benefit a clockwork lamp as much as a clutch lamp; in fact, I think that they do not at all benefit a clockwork lamp.

It would be interesting to learn the opinion of Mr. Charles F. Brush on these points.

Prof. Thomson states that he has run with perfect success clutch lamps "in circuit with coils of such large self-induction that any but very slight fluctuations were wiped out." Surely Prof. Thomson does not mean to say that self-induction wiped out the periodical fluctuations of the current. For this, just the opposite quality, namely, capacity, is required. The self-induction of the coils in this case simply augmented the impedence and prevented the great variations occurring at large time intervals, which take place when the resistance in circuit with the lamps is too small, or even with larger resistance in circuit when the dash pots either in the lamps or elsewhere are too loose.

Prof. Thomson further states that in a lamp in which the feed mechanism is under the control of the derived circuit magnet only, the fluctuations pass through the arc without affecting the magnet to a perceptible degree. It is true that the variations of the resistance of the arc, in consequence of the variations in the current strength, are such as to dampen the fluctuation. Nevertheless, the periodical fluctuations are transmitted through the derived circuit, as one may convince himself easily of, by holding a thin plate of iron against the magnet.

In regard to the physiological effects of the currents I may state that upon reading the memorable lecture of Sir William Thomson, in which he advanced his views on the propagation of the alternate currents through conductors, it instantly occurred to me that currents of high frequencies would be less injurious. I have been looking for a proof that the mode of distribution through the body is the cause of the smaller physiological effects. At times I have thought to have been able to locate the pain in the outer portions of the body, but it is very uncertain. It is most certain, however, that the feeling with currents of very high frequencies is somewhat different from that with low frequencies. I have also noted the enormous importance of one being prepared for the shock or not. If one is prepared, the effect upon the nerves is not nearly as great as when unprepared. With alternations as high as 10,000 per second and upwards, one feels but little pain in the central portion of the body. A remarkable feature of such currents of high tension is that one receives a burn instantly he touches the wire, but beyond that the pain is hardly noticeable.

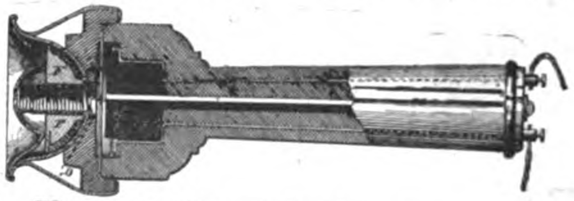
But since the potential difference across the body by a given current through it is very small, the effects can not be very well ascribed to the surface distribution of the current, and the excessively low resistance of the body to such rapidly varying currents speak rather for a condenser action.

In regard to the suggestion of Dr. Tatum, which Prof. Thomson mentions in another article in the same issue, I would state that I have constructed machines up to 480 poles, from which it is possible to obtain about 30,000 alternations per second, and perhaps more. I have also designed types of machines in which the field would revolve in an opposite direction to the armature, by which means it would be possible to obtain from a similar machine 60,000 alternations per second or more.

I highly value the appreciation of Prof. Thomson of my work, but I must confess that in his conclusion he makes a most astounding statement as to the motives of his critical remarks. I have never for a moment thought that his remarks would be dictated by anything but friendly motives. Often we are forced in daily life to represent opposing interests or opinions, but surely in the higher aims the feelings of friendship and mutual consideration should not be affected by such things as these.

WRIGHT AND WILSON'S INDUCTION PREVENTER FOR TELEPHONES.

THE accompanying illustration represents a device for which the inventors, Messrs. Thomas F. Wright and Ed. G. Wilson, of Chicago, claim prevents the disturbing effects of induction. The device is intended for attachment to the ordinary receivers now in use, and consists of a casing of sheet metal, having the external appearance of a small cup which fits snugly within the concavity in the end of the receiver, the interior being concaved around the edges of the cup and provided with a central projecting dome intended to fit against and within the ear.



WRIGHT AND WILSON'S INDUCTION PREVENTER.

The two walls of the casing are provided with central perforations C D, between which a passage is formed by the insertion of a tube E composed of a coil of small steel wire. Surrounding this tube, but enclosed within the casing, is a spool F, grooved externally, as shown, and wound with a coil of fine copper wire, one end of which is driven into the spool, while the free end terminates immediately in front of, but out of contact with, the diaphragm of the telephone-receiver.

This induction-preventing device is attached to the receiver by the spring hook attached to the casing which engages the usual flange upon the end of the receiver.

TESLA'S ALTERNATING GENERATORS FOR HIGH FREQUENCY.

It has now become a common practice to run arc lamps by alternating or pulsating, as distinguished from continuous, currents; but an objection which has been raised to such systems exists in the fact that the arcs emit a pronounced sound, varying with the rate of the alternations or pulsations of current, for which, up to the present, no effective remedy has been found. This noise is due to the rapidly alternating heating and cooling, and consequent expansion and contraction, of the gaseous matter forming the arc which corresponds with the periods or impulses of the current. Another disadvantageous feature is found in the difficulty of maintaining an alternating current arc in consequence of the periodical increase in resistance corresponding to the periodical working of the current. This feature entails a further disadvantage, namely, that small arcs are impracticable.

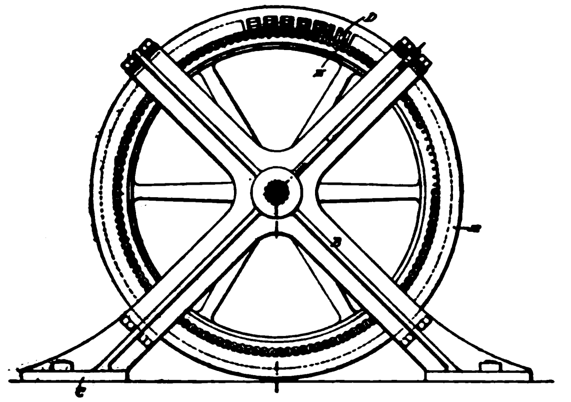


Fig. 1.—Tesla High Frequency Alternating Generator.

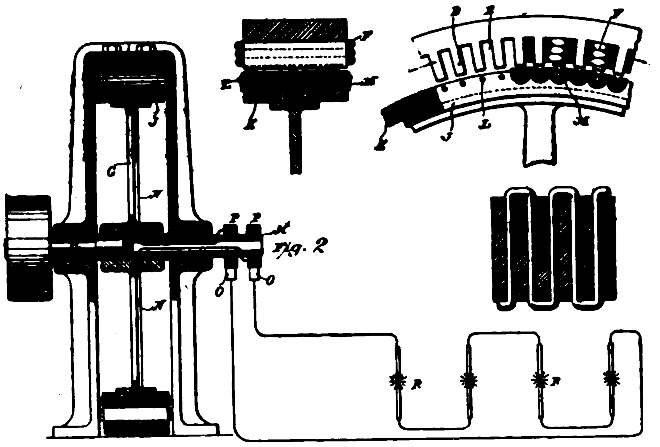
Theorectical considerations have led Mr. Tesla to the belief that these disadvantageous features could be obviated by employing currents of a sufficiently high number of alternations and his anticipations have been confirmed in practice. These rapidly alternating currents render it possible to maintain small arcs which, besides, possess the advantages of silence and persistency. The latter quality is due to the necessarily rapid alternations, in consequence of which the arc has no time to cool, and is always maintained at a high temperature and low resistance.



Figs. 2, 3, 4, 5.—Tesla High Frequency Alternating Generator.

At the outset of his experiments Mr. Tesla encountered great difficulties in the construction of these machines. A generator of this kind is described here, which, though constructed quite some time ago, is well worthy of a detailed description.

In the accompanying engravings, Figs. 1 and 2 show the the machine, respectively, in side elevation and vertical cross-section; Figs. 3, 4 and 5 showing enlarged details of construction. As will be seen, A is an annular magnetic frame, the interior of which is provided with a large number of pole-pieces D.

Owing to the very large number and small size of the poles and the spaces between them, the field coils are applied by winding an insulated conductor F zigzag through the grooves, as shown in Fig. 5, carrying the wire around the annulus to form as many layers as is desired. In this way the pole-pieces D will be energized with alternately opposite polarity around the entire ring.

For the armature, Mr. Tesla employs a spider carrying a ring J, turned down, except at its edges, to form a trough-like receptacle for a mass of fine annealed iron wires K, which are wound in the groove to form the core proper for the armature-coils. Pins L are set in the sides of the ring J, and the coils M are wound over the periphery of the armature-structure and around the pins. The coils M are connected together in series, and these terminals N carried through the hollow shaft H to contact-rings P P, from whence the currents are taken off by brushes O.

In this way a machine with a very large number of poles may be constructed. It is easy, for instance, to obtain in this manner three hundred and seventy-five to four hundred poles in a machine that may be safely driven at a speed of fifteen hundred or sixteen hundred revolutions per minute, which will produce ten thousand or eleven thousand alternations of current per second. Arc lamps R R are shown in diagram as connected up in series with the machine in Fig. 2. If such a current be applied to running arc lamps, the sound produced by or in the arc becomes practically inaudible, for, by increasing the rate of change in the current, and consequently, the number of vibrations per unit of time of the gaseous material of the arc up to, or beyond, ten thousand or eleven thousand per second, or to what is regarded as the limit of audition, the sound due to such vibrations will not be audible. The exact number of changes or undulations necessary to produce this result will vary somewhat according to the size of the arc—that is to say, the smaller the arc the greater the number of changes that will be required to render it inaudible within certain limits. It should also be stated that the arc should not exceed a certain length.

The difficulties encountered in the construction of these machines are of a mechanical as well as an electrical nature. The machine may be designed on two plans: the field may be formed either of alternating poles, or of polar projections of the same polarity. Up to about 15,000 alternations per second in an experimental machine, the former plan may be followed, but a more efficient machine is obtained on the second plan.

In the machine above described, which was capable of running two arcs of normal candle power, the field was composed of a ring of wrought iron 32 inches outside diameter, and about one inch thick. The inside diameter was 30 inches. There were 384 polar projections. The wire was wound in zigzag form, but two wires were wound so as to completely envelop the projections. The distance between the projections is about $\frac{3}{16}$ inch, and they are a little over $\frac{1}{16}$ inch thick. The field magnet was made relatively small so as to adapt the machine for a constant current. There are 384 coils connected in two series. It was found impracticable to use any wire much thicker than No. 26 B. and S. gauge, on account of the local effects. In such a machine the clearance should be as small as possible; for this reason the machine was made only 1½ inch wide, so that the binding wires might be obviated. The armature wires must be wound with great care as they are apt to fly off in consequence of the great peripheral speed. In various experiments this machine has been run as high as 3,000 revolutions per minute. Owing to the great speed it was possible to obtain as high as 10 amperes out of the machine. The electromotive force was regulated by means of an adjustable condenser within very wide limits, the limits being the greater, the greater the speed. This machine was frequently used to run Mr. Tesla's shop lights.

The machine above described was only one of many other types constructed. It serves well for an experimental machine, but if still higher alternations are required and higher efficiency is necessary, then a machine on a plan described in Figs. 6 to 9, is preferable. The principal advantage of this type of machine is that there is not much magnetic leakage, and that a field may be produced, varying greatly in intensity in places not much distant from each other.

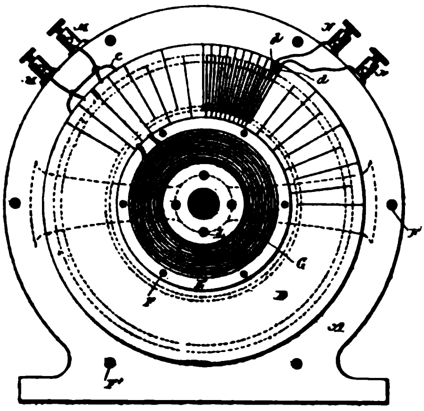


FIG. 6.—TESLA HIGH FREQUENCY ALTERNATING GENERATOR.

In these engravings, Figs. 6 and 7 illustrate a machine in which the armature conductor and field coils are stationary, while the field magnet core revolves. Fig. 8 shows a machine embodying the same plan of construction, but having a stationary field magnet and rotary armature.

The conductor in which the currents are induced may be arranged in various ways; but Mr. Tesla prefers the following method: He employs an annular plate of copper D, and by means of a saw cuts in it radial slots from one edge nearly through to the other, beginning alternately from opposite edges. In this way a continuous zigzag conductor is formed. When the polar projections are $\frac{1}{8}$ inch wide, the width of the conductor should not, under any circumstances, be more than $\frac{1}{32}$ inch wide; even then the eddy effect is considerable.

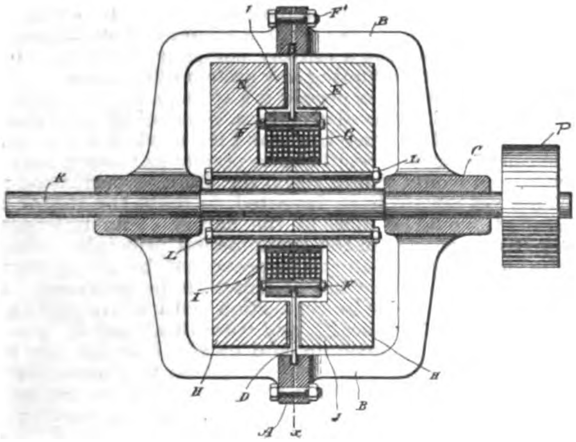

FIG 7.—TESLA HIGH FREQUENCY ALTERNATING GENERATOR.

To the inner edge of this plate are secured two rings of non-magnetic metal E, which are insulated from the copper conductor, but held firmly thereto by means of the bolts F. Within the rings E is then placed an annular coil G, which is the energizing coil for the field magnet. The conductor D and the parts attached thereto are supported by means of the cylindrical shell or casting A A, the two parts of which are brought together and clamped to the outer edge of the conductor D.

The core for the field magnet is built up of two circular parts H H, formed with annular grooves I, which, when the two parts are brought together, form a space for the reception of the energizing coil G. The hubs of the cores are trued off, so as to fit closely against one another, while the outer portions or flanges which form the polar faces J J, are reduced somewhat in thickness to make room for the conductor D, and are serrated on their faces. The number of serrations in the polar faces is arbitrary; but there must exist between them and the radial portions of the conductor D a certain relation, which will be understood by reference to Fig. 9, in which N N represent the projections or points on one face of the core of the field, and S S the points of the other face. The conductor D, is shown in this figure in section a a' designating the radial portions of the conductor, and b the insulating divisions between the same. The relative width of the parts a a' and the space between any two adjacent points N N or S S is such that when the radial portions a of the conductor are passing between the opposite points N S, where the field is strongest, the intermediate radial portions a' are passing through the widest spaces midway between such points and where the field is weakest. Since the core on one side is of opposite polarity to the part facing it, all the projections of one polar face will be of opposite polarity to those of the other face. Hence, although the space between any two adjacent points on the same face may be extremely small, there will be no leakage of the magnetic lines between any two points of the same name, but the lines of force will pass across from one set of points to the other. The construction followed obviates to a great degree the distortion of the magnetic lines by the action of the current in the conductor D, in which it willl be observed the current is flowing at any given time from the centre toward the periphery in one set of radial parts a and in the opposite direction in the adjacent parts a'.

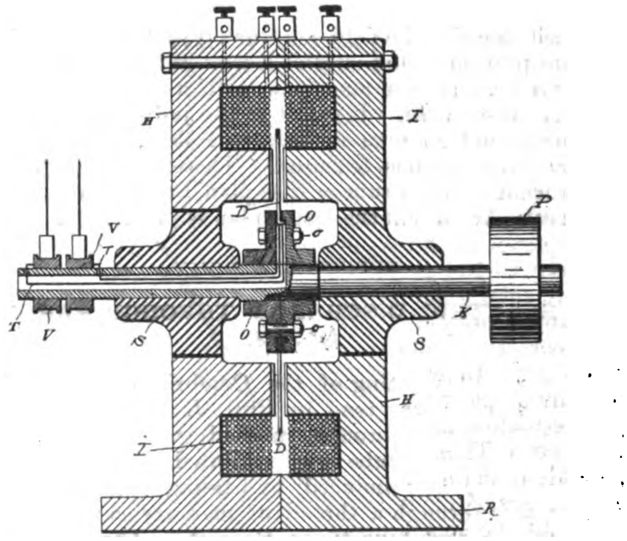

FIG. 8.—TESLA HIGH FREQUENCY ALTERNATING GENERATOR.

In order to connect the energizing coil G with a source of continuous current, Mr. Tesla utilizes two adjacent radial portions of the conductor D for connecting the terminals of the coil G with two binding posts M. For this purpose the plate D is cut entirely through, as shown, and the break thus made is bridged over by a short conductor C. The plate D is cut through to form two terminals d, which are connected to binding posts N. The core H H, when rotated by the driving pulley, generates in the conductors D an alternating current, which is taken off from the binding posts N.

When it is desired to rotate the conductor between the faces of a stationary field-magnet, the construction shown in Fig. 8 is adopted. The conductor D in this case is made in substantially the same manner as above described by slotting an annular conducting-plate. The field-magnet in this case consists of two annular parts H H, provided with annular grooves I for the reception of the coils. The flanges surrounding the annular groove are brought together, while the inner flanges are serrated, as in the previous case, and form the polar faces.

In a type of machine of this kind, constructed by Mr. Tesla, the field had 480 polar projections on each side, and from this machine it was possible to obtain 30,000 alternations per second. As the polar projections must necessarily be very narrow, very thin wires or sheets must be used to avoid the eddy current effects. Mr. Tesla has thus constructed machines with a stationary armature and rotating field, in which case also the field-coil was supported so that the revolving part consisted only of a wrought iron body devoid of any wire, and also machines with a rotating armature and stationery field. It is left to the judgment of the experimenter which plan is best to follow, each promising certain advantageous features. These machines may be constructed on the drum or disc plan, but the experience of Mr. Tesla shows that the latter plan is preferable.

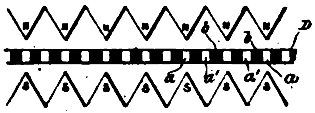

FIG. 9.—TESLA HIGH FREQUENCY ALTERNATING GENERATOR.

THE ELECTRIC DISCHARGE THROUGH RAREFIED GASES.

At a recent meeting of the Cambridge Philosophical Society, a paper was read by Prof. J. J. Thomson on the electric discharge through rarefied gases without electrodes. A vacuum tube was exhibited, in which an electric discharge was induced by passing the discharge of Leyden jars through a thread of mercury contained in a glass tube coiled four times along it. The induced discharged was found to be confined to the part of the vacuum tube which was close to the primary discharge, and it did not show striæ. It was also demonstrated that an ordinary striated discharge is strikingly impeded by the presence of a strong field of magnetic force.

ELECTROSTATIC MEASURING INSTRUMENTS.

THERE would seem to be, says *Industries*, some kind of prejudice against the use of electrostatic measuring instruments. Generally, in an alternating-current station, we find the high-pressure leads connected to transformers reducing to 100 volts or so, and a hot-wire voltmeter employed to read by. The transformer takes, say, 30 watts, probably more, and the voltmeter another 30. This means 500 kilowatt hours per annum wasted. At 5 cents this comes to $25 a year, which is the interest on from $250 to $500. A laboratory electrometer was used in electric engineering by Joubert in 1881, and others have been used occasionally since by Profs. Ayrton and Perry, Ryan and Monnier. Sir William Thomson has, however, introduced a number of electrostatic instruments, reading from 100 volts upwards, and engineers who use them do not revert to electro-magnetic or hot-wire voltmeters. Electrostatic instruments not only take no power, but have no temperature errors, and do not need corrections for frequency, and no doubt they will eventually be cheaper than other forms.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER *150 Broadway, New York city.*

THE QUESTION OF RAILWAY MOTOR GUARANTEES.

I have read with no little interest an article in your last issue, entitled "Electric Railway Guarantees," by A. H. Chadbourne, which is, in effect, an attempt to apologize for the short life of an armature by showing the unreliability of the men who supervise its use. Mr. Chadbourne is unquestionably right. If the electrical world had men who would nurse an armature, as its short life requires that it should be, there is no doubt whatever that its numbered days would be somewhat lengthened. Such a procedure is proportionately true of almost anything used in connection with machinery; true of nearly everything that exists. As Mr. Chadbourne correctly states, the refusal of a company to guarantee its motor is a "sticker," and one that will always "stick" until some one has invented an armature that will not be open to such an objection as is prompted by the inquiry. The strongest point made by Mr. Chadbourne lies in the statement that a company should "First guarantee the superintendent before we guarantee our machinery." Everyone knows that in all walks of life, whether it is in art, mercantile life, manufacturing, railroad, finance, marine, governmental, artisan, or what not, the *experts* are few; the *good* men not galore; the *medium* men in very much lesser number than the "good," and the poor, indifferent fellows in distressing majority. This is historically true, and the situation is not remedied by giving us a *weakling* to be taken care of by a *poor* nurse.

It is because companies cannot rely upon men to do their duty, that an armature is needed that will not require any more than casual attention.

In the present state of mind that is anxiously watching for developments in the electrical field, there is undoubtedly not so much a seeming want of faith in what has been invented as a fear that the adoption of a certain system may preclude the adoption of something better that may spring up suddenly like a jack in a box. This is a natural fear and is much augmented by the fact that a change of systems on a horse, or other, railway means the expenditure of a great deal of money, as well as involving no end of trouble, etc. It is, therefore, not to be wondered at that a railway company should hesitate before awarding a contract that would involve so much to them.

An armature of which there is any doubt at all, should not be considered seriously by any railway company, no matter how many careful superintendents and attentive men they may have on hand to supervise its working. In a matter of such importance, *doubt* should not exist and a railway company would not be doing justice to itself by adopting any system other than a reasonably perfect one. What is needed is a storage battery motor car that is safe with a long-lived armature, economical and durable, and such a one will, in time, command the market of the railway world, simply because it would be as perfect as human invention can devise, and would almost reach the limit of perfection; and what would yet remain to be invented, to make the motor absolutely perfect, would be more in the nature of an unimportant auxiliary than a change in the fundamental principle. An armature, the burning of which can be prevented by the application of a perfectly devised mechanical clutch, *is in existence.* Such an armature is now used in connection with a storage battery that is "safe" "economical" and "durable," and if you will pardon me (as I am the inventor and owner) I would say that I am reasonably sure that the desideratum is now furnished, the confirmation of which claim is in the fact that a severe test has been repeatedly made for seven months, day and night; in all kinds of weather, varying and annoying grades, and in short under all such trying conditions as have forced the severest possible test that can be had, with a view to arriving at a practical and common-sense result.

Arrangements are now making for the presentation of my system to the railway market, and, if Mr. Chadbourne will only exercise a little patience, he will not be harrassed nor worried in an attempt to unstick the "sticker" that is being so successfully stuck into him and others interested in the subject.

J. F. M'LAUGHLIN.

PHILADELPHIA, March 12, 1891.

PROF. A. G. BELL has given $25,000 to the Association for the Teaching of Speech to the Dumb, of New York.

THE INVENTIONS OF THOMAS DAVENPORT.[1]

BY FRANKLIN L. POPE.

THE year 1837 marked a very important era in the history of the industrial development of electricity. During that year, two of the most extraordinary inventions of the present century made their advent in this city—the electric telegraph of Prof. Samuel F. B. Morse, and the electric motor of Thomas Davenport. The motor came first. Davenport, a self-taught Vermont blacksmith, who had invented and constructed his machine in a remote country village in a crude form as early as 1834, came to New York in February, 1837, bringing with him some of the machinery which had been made for the purpose of exhibition, by himself and Ransom Cook, with a view to enlisting capital to build a large motor. During the season of 1837 he occupied rooms in the city where he exhibited models of his motor and various other electrical inventions. Articles were published in the newspapers of the day, and his exhibitions were attended by a great number of people. In letters written about that time, Davenport mentioned that one of the most frequent visitors was Professor Morse.

With the history of Professor Morse and his inventions of the telegraph the world is quite familiar. With the history of Davenport and of the invention of his electric motor—as I soon discovered in endeavoring to obtain information about it myself—scarcely anything was known. This difficulty ultimately led me to interest myself in trying to find out more about the matter. In this undertaking I was fortunately very much more successful than one can reasonably expect to be, in attempting to resuscitate the history of an invention which has lain unknown for the best half of a century.

The first newspaper notice of the electric telegraph which appeared in America was in the *New York Observer* in the summer of 1837. I will read you an extract from it:

"A gentleman of our acquaintance several years since suggested that any intelligence might be communicated almost instantaneously hundreds, if not thousands of miles, by means of very fine wires, properly coated to protect them from moisture and extending between places thus widely separated. It is well known that the electric fluid occupies no perceptible time in passing many miles on a wire, and if it is possible by connecting one end of the wire with an electrical or galvanic battery to produce *any sensible effect whatever* at the other, it is obvious that if there are twenty-four wires, each representing a letter of the alphabet, they may be connected with the battery successively in any order, and if so connected in the order of the letters of any word or sentence, that word or sentence could be read or written by a person standing at the other end of the wires. All the paragraphs of a newspaper could thus be touched by a man in Philadelphia, and the contents, *verbatim et literatim* conveyed to New York as fast as a compositor could set up the type!"

It has always been a mystery to me what invention was referred to in that article. *The New York Observer* was edited at that time by a brother of Professor Morse. The "gentleman of our acquaintance" referred to, was no doubt Professor Morse, but what was meant by the telegraph of twenty-four wires I could never make out, because we all know that Morse never entertained any idea other than that of a single-circuit telegraph at any time from the beginning of his experiments in 1835, or earlier. But I received a few days since a letter from a gentleman who had read some articles recently published by me in reference to Davenport's work,[2] in which he stated that he visited Davenport's exhibition in the summer of 1837, here in the city of New York, and that he himself saw in that exhibition a model of a telegraph of twenty-four wires invented by Davenport, and that model must undoubtedly be the telegraph referred to in the extract I have just read.

In pursuing my investigations into the history of Davenport's work, I was fortunate enough to find that several of his original models were still in existence. One of these models, a circular railway two feet and a half in diameter with a locomotive traveling on it, similar to the one which we have here to-night but very much more finely finished, I was able to satisfy myself by contemporaneous evidence was built in 1837. The one which is before you was found in the cabinet of the Female Seminary in Troy, formerly Miss Willard's. The records of the institution show that it was purchased in 1840, but it evidently must have been built by Davenport himself prior to the more finely finished model of which I have just spoken, which was constructed in 1836-7 with the assistance of Mr. Ransom Cook, of Saratoga, a very ingenious person and a finished mechanic. I think there is no doubt that the model before us was built in the early part of 1837 and possibly as early as 1836. Fortunately it is, as you see, in a very good state of preservation. I have had it mounted to-night with the same battery that was found with it—a three-cell Grove battery of pint cups, and I think we shall find that it is in tolerably fair running order. [The model was set in motion.] It does not go quite a hundred and twenty miles an hour, but it goes. This locomotive, you will observe, has a fixed field magnet below, and a revolving armature above, which is reversed twice in every revolution. So far as I am able to discover, that is a combination found in every practical motor to-day, which Davenport was the first to make known and to use in 1834. The motor is connected to the driving axle by bevel-gear. The field and armature in the model before you are connected in series. In the other model of 1837 of which I spoke, they are connected *in shunt*. Among other models of Davenport was one having a horse-shoe field and a four-pole armature with curved pole-pieces, which is really quite an advanced type of motor. That also was built in 1837. Altogether, Davenport, between 1834 and 1840, built over 100 motors of different patterns and of varying sizes, scarcely any two of them alike. I discovered also, quite to my surprise, that he was undoubtedly the first to make use of the solenoid with a movable core, as a means of moving machinery of any kind. He built in 1839 quite a large motor operating upon that principle, which from the best description I have been able to find of it, must have approached one horse power. He set that up at 42 Stanton street, in New York; attached a printing press to it and started to publish the pioneer electrical journal of America—a small weekly paper called "The Electro-Magnet and Mechanics' Intelligencer," printed by electrical power. Through the kindness of Mr. Davenport's son, Rev. Willard G. Davenport, I have the pleasure, on his behalf, of presenting to the American Institute of Electrical Engineers two copies of that paper. [Applause.] These, so far as is known, are the only editions ever published; they are number one and number two. This was in 1840. I have received within a day or two an interesting letter from Mr. H. S. Davenport, a nephew of Thomas Davenport, still living in Vermont at an advanced age, who, as a boy, was with him a great deal and in that way became quite familiar with his work. I will take the liberty of reading extracts which give some idea of the manner of man Mr. Davenport was. He says:—

"Many of his models never left his shop and were but little known even at the time of their construction. They were only made to show to how many uses the power could be applied, and also to work from on a larger scale, if he could get pecuniary aid to do so. The different models which interested me most, at the several times I was in his shop, were a trip-hammer, a turning lathe and a machine for doubling, twisting and reeling cotton or silk, all at the same time. A circular frame fitted with two intersecting tracks, on which four miniature cork images glided around, he called his "puppet-show." He was naturally of a retiring disposition, but when waked up was very strong in argument. His two favorite subjects were nature and electro-magnetism. He considered magnetism the most important element in the creation of the universe and thought it would be in its destruction. Magnetism kept the heavenly bodies in their places, and if that failed everything would be turned to chaos. He could see in every rock of the earth the battery of which it was composed. So also in the animal kingdom, the bones, muscles, and blood constituted a complete battery, which exercised a repulsive or attractive force with respect to another organism of the same kind. He was a great lover of fun and exceedingly fond of a joke. On one occasion he received an order from a party in Chicago for half-a-dozen bottles of electricity. He said he knew by the tenor of the letter that it was intended as a joke, and he accordingly replied that he bottled up his *wrath* for such would-be ignoramuses as he was, but had no electricity for him."

I might go on and relate many other facts of interest which I have learned about Mr. Davenport and his inventions, but the hour is already late, and I will forbear. But I may remark in conclusion, that I find him to have been one of the most interesting characters with whom I have ever become acquainted, and I cannot but feel highly gratified that my attention chanced to be directed to the subject, in season to rescue at least some of the more important of his work from impending oblivion. In two or three years more it would have been too late. There are people now living, although at an advanced age, who knew him and remember him perfectly, but in a year or two more perchance they will be gone. [Applause.]

ELECTRIC LIGHTING AT TUSSAUD'S WAX WORKS.

A correspondent of the London *Electrician* states that at Madame Tussaud's wax works exhibition, a single arc lamp has displaced 500 gas jets for illuminating the entrance hall and grand staircase.

MR. ALLAN V. GARRATT.

The above named gentleman, who is well-known in electrical circles, went West recently to establish himself, and has now opened offices as an electrical engineer and contractor at Spokane Falls, Wash. He is already actively at work there, and has now organized the Spokane and University Heights Street Railway Co., of Spokane Falls, which will build and equip 6 miles of electric road in the spring. The officers of the company are: Allan V. Garratt, president and general manager; Robert Abernethy, vice-president; and L. B. Cornell, secretary.

INSTITUTE DISCUSSION ON HIGH-SPEED ELECTRIC RAILWAY WORK.

The following is an abstract of the discussion of Mr. O. T. Crosby's paper entitled "Report of High-Speed Electric Railway Work" read before the American Institute of Electrical Engineers on Feb. 24, 1891.

Mr. W. H. Pierce inquired if Mr. Crosby had made any calculations or estimates as to how far and how long the train would run before it would attain a speed of 150 miles, and how far it would have to run before it could be stopped.

Mr. Crosby replied that the space for stopping, with a braking power that would just fail to slide the wheels, would be just about 7,000 feet and the time would be in the neighborhood of 100 seconds. The time of getting the train to speed with the motors as designed, is in the neighborhood of two or three miles.

Mr. Crosby :—I should say that I do not think there is anything whatever in high-speed work for, say, even forty miles. I do not think you can properly do 120 miles an hour for a run of say thirty or forty miles. It is applicable only to connecting very large cities. I think you could run from here to Albany, if you had the New York Central line to run on; from Albany to Rochester, from Rochester to Buffalo, and then stopping at the principal lake cities. It might be found later on that it would be necessary to make shorter stops, but the first effort should be made only with very long runs.

Mr. F. L. Pope :—In conversation some time ago with a prominent civil engineer, at one time professionally connected with the Lake Shore road, he expressed the opinion that safety from derailment at very high speeds would be best secured by very slightly curving the line of the road just sufficient to cause the flanges of the wheels to bear constantly against one side. With that construction he should expect that any possible speed, up to, say, 200 miles an hour, that could be got from the motors, would be perfectly safe. He was led to this conclusion from long observation of the performances on the Lake Shore road of railroad wheels at high speed, on which road some of the best running in this country has been done.

Mr. Thomas D. Lockwood remarked that the best speed he had ever known to be made out of an average of a great many trips had been done by way trains where the stations were very close together, and the reason of that is, that upon a long run you can obtain a fairly high average without even getting an immensely high speed, whereas upon way trains, where the stations are very frequent, we often have to run at enormously high speed between stations to maintain the time, and that is often when we have runs of only two miles between stops. He also inquired whether Mr. Crosby had any decided opinion on the value of the method of increasing traction by means of passing a current between wheel and rail.

Mr. Crosby, as the result of his experiments, did not think that the method possessed any value. He knew of experiments which were never published but which were made by a man much interested in the subject at one of the great universities of the country which indicate that in a three or four pound model it took something like two hundred amperes to produce any effect, and that was plainly a welding effect, since it showed a clear pitting of the little rail on which this model used to run.

He did not consider the matter of return of energy to the line, because they wanted all the power they could get, and because the number of stops was very small compared with the number of miles run. It might be different, say, on the elevated railway service. It might do to run the motors as dynamos and let them give back the work of retardation into the line. But you make a little sacrifice to do that. That is, you have got to work your motors at lower than saturation point for your normal work. Otherwise he did not see how one can get the electromotive force of the motor high enough to pump back into the line. For that reason he did not think it had any place in long distance work where the stops are one in a hundred miles. In answer to a question of Mr. Pierce, Mr. Crosby said that he assumed thirty-three per cent. drop on the line, and had done so all along, thinking that it would be practicable to have that; although he did not know that it would be the most economical drop, not having calculated.

Mr. Edward P. Thompson inquired whether it were practicable to run an automatic electric train for the purpose of carrying mail matter and other objects of great value where it is necessary to have high speed? As regards brakes for stopping high-speed trains, the principal point is economy. He found in some tests he had made in behalf of a brake company upon a railway in Pennsylvania, that if it needs a certain amount of energy to start a train, it needs about nine-tenths as much to make an emergency stop. In local or accommodation trains the expense would be enormous, therefore, to so frequently reduce the speed as soon as it reached 120 miles an hour, if the electric current were used as the braking power. In the experiments referred to, the momentum of the train was used for braking, while the electric current was merely the agent for controlling the application of the force of momentum. This force is very cheap and plentiful, and even with the crude apparatus employed, emergency stops were made in which the cost was simply that of an electric current of two amperes acting for less than one second.

Mr. Crosby :—In order to have any kind of service, whether you try it automatically or not, you have got to have it safe enough for a man to be on the car. That is, you must not have so many accidents as would make it unsafe for a man to go on there, or your business would be gone. If you have an engineer he can have a man to sit by him and another man by him, and you go on till finally you have a passenger train. [Laughter.] I do not consider it practicable to run a train that is of any size, enough to make it commercial, without a man on it. I think the enormous complexity of an automatic system that would take care of the entrance into a city and the departure from a city and of all the varying conditions of service, without a man on board, is really beyond anything that would stand up. You might put it all down to work and have trains on it, but I think the complexity would soon break it down. I think the limitation, so far as steam railways are concerned, is the ability of the engine to draw enough cars to accommodate people who want to go at that speed. That is what the New York Central people claim in regard to their limited train to Chicago. They cannot run any more cars and have their engines make the speed that is wanted. People at Buffalo complain that they cannot get the fast service which people going from here to Chicago get. They have wanted additional cars put on, and the railway company has answered, We cannot put on additional cars without sacrificing what we are aiming at, which is high speed.

Dr. P. H. Dudley :—I have made experiments on the resistance of different trains. Those were made several years ago and not on as good tracks as we have at the present time. The resistance of the passenger train is given by the formulæ in books, as seventeen or eighteen pounds per ton. I found on the Lake Shore Michigan Southern Railway and the New York Central & Hudson River Railroad that with trains of about 250 tons the resistance was only from ten to twelve pounds per ton at speeds of from fifty to sixty miles per hour. The resistance per ton is not nearly so great on those long trains, as on the short ones. With trains of two and three cars, sometimes it ran as high as thirty-five or forty pounds per ton, but with long trains it ran down to about ten and twelve pounds per ton.

The greatest variable that we find from day to day over the same track and same train is the wind resistance. I found in one special experiment I made in 1878 to see why the New York Central was not able to make its time with its trains, that on a still day, with the schedules they had, they were able to make time, but a wind of ten or twelve miles would retard the trains so that in running from Buffalo to New York they would loose two hours. The trouble at that time was that the boilers were not large enough to quickly generate the steam required to meet the increased resistance. The trains would run up to a speed just about the capacity of the boiler and that would limit the speed they could maintain. Therefore when a head or side wind was blowing against them, the speed of the train would be reduced very materially.

One gentleman spoke about the fast speed of the local passenger trains. The fastest speed usually found on trains is in the local passenger service, for five to twenty seconds—especially those stopping every two or three miles. They often attain a speed for a few seconds as high as fifty-five or sixty miles per hour. Then they shut off steam and apply the brakes to stop the train. The heavy trains of eight to ten cars, running long distances, rarely attain sixty miles an hour, that is on the ordinary schedules.

The greatest improvement that has been made in decreasing train resistance is in the improvement of the track by bringing up the standard of excellence and adoption of heavier and stiffer rails. I have been making a number of heavy rail sections for different railroads, and instead of making them simply heavy, I had made them very stiff, which has reduced the deflection or wave motion under each of the wheels. Comparing the resistance of the Chicago Limited Express on stiff eighty pound rails, with that of sixty-five pound rails which have been on the track some time, it makes a difference of seventy-five to one-hundred horse power per mile. I have just made some ninety-five pound rails for a road, which will be very much stiffer than the eighty pound rails. We find now that the condition in which they are keeping the line is so perfect that there is scarcely any oscillation on the best roads, and there is very little difference in the oscillation now in riding on a tangent or a curve. I should prefer a tangent for smooth riding, although the wheels press against the rails on curves. Unless they are properly elevated, there will be some oscillation, though our present trains move very steadily on the best tracks. I have made careful experiments, and with a track in good condition the heavy cars ride very steadily, leaving little to be desired.

Mr. C. O. Mailloux :—I found that the ordinary data in relation to the traction on street railroads are entirely unreliable. Various estimates have been given by civil engineers and others for the electrical traction per ton for a street car. The most authentic figures placed the traction at something like 18 pounds per ton. In practice, as the result of the crude traction-dynamometer experiments just mentioned, I have found the traction below twenty pounds with a car having a considerable weight. I have found that the traction per ton reached in some cases over thirty pounds and it has gone as high as forty pounds. Calculating the traction theoretically, using the coefficient of friction on the axle, the weight and the well-known formula (since the power exerted is expended practically in overcoming the friction of the axles), one would expect to find a much lower traction. As a matter of fact, calculation gives a figure which is nearly in accordance with the data given by the engineers; yet practice always gives a higher figure by fifty per cent. and often more. I concluded from this that as the car is being continually lifted slightly we must introduce into the formula for traction a factor which is a function of the weight of the car itself; in other words, that the traction per ton increases with the weight of the car. I mean that the traction per ton for a car weighing three tons might be twenty or twenty-five pounds, while that of a car weighing seven or eight tons under the same circumstances might be probably thirty or thirty-five pounds. This view might explain the lower figures found for the traction of horse cars, these being of so much smaller weight. I would like to ask Mr. Crosby in regard to the initial torque; that is, the amount of traction which is necessary to overcome static friction; in other words, what he finds the difference between static and kinetic friction to be. I have found in my experience that the initial traction went up as high 80 to 100 pounds per ton.

Mr. Geo. B. Prescott, Jr., confirmed what Mr. Mailloux said about the unreliability of the traction figures for street cars that are given in some text books. In experiments he had made in Boston he had found that on a perfect level the traction to be somewhere in the neighborhood of 30 pounds to the ton for a car weighing about six tons.

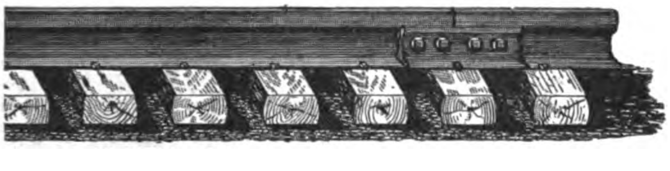

Fig. 1.—Rail in Good Condition.

Dr. Wm. E. Geyer inquired if the same attention were paid to the track, what would be the possibilities with ordinary steam locomotion, if we were willing to spend large sums of money on the track and on maintenance, approximately as proposed by Mr. Crosby.

Dr. P. H. Dudley:—Our experiments are not sufficiently carried out to determine yet all those points. About the best results are those that I have given you, that is, a reduction of nearly one hundred h. p. per mile, compared with the ordinary sixty-five pound rail. I have designed some one hundred and five pound rails which are nearly one hundred per cent. stiffer than the eighty pound rails. We will probably save on the fast express trains nearly two hundred h. p. per mile, as compared with worn 60 or 65 lb. rails. We have not rolled such a large rail yet; but it will not be long, probably, before that will be done. All trials show a very material reduction in train resistance with the heavy rails, as we increase the stiffness. I think it will be perfectly safe on a track of the 105 lb. rails, to run 120 miles an hour. I have ridden several times seventy-five miles an hour on heavy rails and did not feel it nearly so much as on the light rails when running forty-five miles an hour. There is scarcely any oscillation. The track is in perfect line and the joints are all kept up. I might show you the shape of some of the rails we find in tracks. Taking a thirty foot rail on our best tracks; its surface to the eye would be represented by a straight line. [See Fig. 1.] The joint is well maintained in uniform surface with the other portions of the rail. Take even sixty-five pound rails, after they have been run over a little while, if the joints are laid opposite, we find the rails in this form. [See Fig. 2.] Down at the joints and high in the centre. Now, of course, as the locomotive or train is passing over this depression, it further deflects and the wheels strike on the receiving end of the rail and cut out a piece from the head of the rail. This has been very common. Sometimes the effect is sufficient also to bend the rail down at this point. The apparatus I have on my car ejects paint on the rails where there is a certain deflection. In Fig. 2, it will be noticed the receiving ends of the rails are commencing to cut out. By ejecting the paint, the trackmen have been able to surface the track so that on rails 15 or 16 years old, they have not only checked the cutting out, but have brought up the surface of the rails to a much better condition, and they are nearly in a straight line at the present time. One serious trouble with many of the railroad people is, that while they want a heavy rail, they never consider the question of stiffness. I distribute my metal so as to make the section very stiff, not allowing so much in depth of the head of the rail as usually is done, but widening the head, because when these rails have been in the track a few years, they become worn very unevenly, and must be removed from the track. I am making the heads on that account very much broader and the sections stiff, so the deflection of my 75 and 80 lb. rail is less than one-tenth of an inch in the track. We mark all those rails for any deflection exceeding three thirty-seconds of an inch, under a load of six tons per wheel. That is about as close as the trackmen can work on a sixty-five pound rail. On an eighty pound rail they can work closer, but require great skill. The ejection of paint also shows where there is a rotten or loose tie. The form of rail where the joints are low, and high in the centre, I call the first form. Then there is another form in which the joints and centre are low, and high at the quarters, which I call the second form. [See Fig. 3.] Then there is another rail of which the surface is all full of waves. I call that the third form. [See Fig. 4.] A few years ago that was a very serious matter. We are often able to tell from the diagrams in the car, what mill made the rails as we run over them. That feature has been materially improved by the mills. You will see at once, with trains running over rails of these various forms and with the deflections, there is a large amount of force lost. Rails high in the centre to the eye, will be loose on the ties, so that there is quite a wave under each wheel. Even with very good track we find that under each wheel there is a depression depending on the weight on the wheel and speed of train.

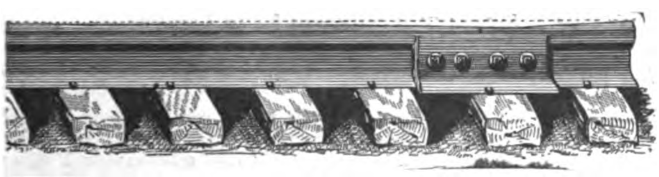

Fig. 2.—Rail Worn Down at Joints.

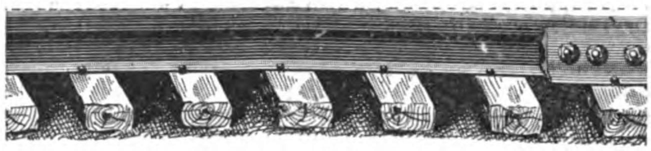

Fig. 3.—Rail Low at Joints and Centre.

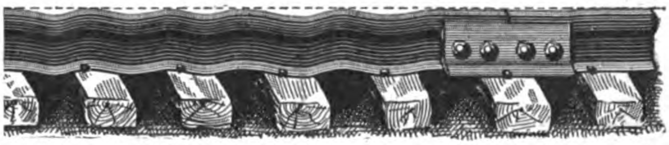

Fig. 4.—Rail With Wavy Surface.

Mr. Lockwood drew attention to the fact that with the increased use of electric locomotives, we may expect to have better preserved tracks, and tracks which, moreover, will hold out much longer; because in the transfer of the rectilinear motion of the steam-piston to its connecting rod and its transformation to rotary motion in the wheels, there is a heavy pounding effect, which will certainly be absent from the motor which has a rotary motion at the outset.

Mr. Frank J. Sprague:—I wish to take the decided position that no automatic system of high-speed service for either passenger, freight, or mail will ever come to a commercial issue. I will go further still: the moment you deny to a man the privilege of traveling 100 or 150 miles an hour you will have a flood of applications from people that want the opportunity.

Mr. Crosby spoke of the possibility of returning the energy of the train to the line, and that it would have very little importance in dealing with the particular class of service of which he has spoken—high-speed service over long distances. That is very true. I think perhaps the value there of a shunt machine, if used, would be on account of the constancy of the speed. That is, it would always be constant within a certain very small limit, especially with machines of the exceedingly high efficiency which would be used under those circumstances. That is where I think, perhaps, the shunt machines would be used. But on local rapid transit service, or service like that of the elevated railroads of New York City—which is not very rapid—but where we have stops every third of a mile, then the importance of returning energy to the line becomes at once very great, because from careful calculations I know it to be possible to return about forty per cent. of the total energy used, back to the line, and the facility with which this can be done increases very rapidly with the size of machine which is used. Where you can use shunt machines, and excite your field magnets up to a very high saturation, and have a very reasonable latitude of variation, the criticism that was made that there would be a loss in energizing the field-magnets more than when in using series machines, I do not think holds particularly good, for this reason: that the total energy used in the field-magnets forms a very small proportion of the total amount of energy used on the line, and if the return energy is forty per cent. of the total, and the field energy of the magnet is only two or three per cent. of the total, the value of this method seems apparent.

The question of traction which has been so ably spoken of by Dr. Dudley has two entirely different bearings. If you are dealing with street car service, it is one thing. If you are dealing with high-speed, clean rail service, it is an entirely different thing. I have found, so far as my practical experience goes, that the dirt on the track, the snow and mud, and the grades, were the questions that determined the power of the motors. When you consider that with twenty pounds traction per ton, the work on a one per cent. grade is equal to the work of traction, and that our street car service demands 12, 13, and even 14 per cent. grade work, the question of rail traction on a level amounts to very little in street car motor design, but it does amount to the greatest possible importance in high-speed service.

Mr. Crosby was speaking, just as I came in, of the influence of currents on traction where the ground circuit is used. I was once a very zealous upholder, especially through our commercial agents, of the importance of using the ground circuit, because of the value of adhesion. My belief was founded on the experience I had with a very dirty track, for which the electricity was perhaps a sort of broom to brush away, or a fire to consume the dirt. I am now of the opinion that the passage of the current, or at least so much current as is necessary for actual traction, has little actual influence on actual adhesion with clean rails. If it has any influence, it simply acts as a cleaner of the track—nothing more than that. [Applause.]

Mr. J. Stanford Brown inquired what limitations would be put upon curvature in this very high-speed service.

Mr. Crosby:—In the paper as read there is a calculation for the limit of curvature as a question of safety. Now there is a very important question as to the effect of curvature in increasing the friction coefficient. On that I have been able to do nothing more than take the text-book formula, and I am not at all sure that they are all right. The matter of safety I have discussed in the paper. The power I have assumed ordinary coefficients for. As to the values of the coefficients in street railway work on straight track, I found with a dynamometer on an ordinary flat rail, about twenty-five pounds average per ton for a car weighing about twelve thousand pounds, that is, a street car, on an average street car track. As to the starting effect, I started a car equipped with the ordinary Sprague motor with fourteen amperes by having a water resistance external to the car. Of course all cars as they are made by all the companies that I know of, take a larger current than that to begin with under any conditions, simply because *C* is equal to *E* divided by *R*. But that current is many times larger than is necessary to start a car. Those 14 amperes started a car on what was practically a level, rusty track; then I put a dynamometer in to check it, and, as I remember now, got about 175 pounds as the effort, applied gradually through a rope and a dynamometer to the starting of this car. That would be about thirty-five pounds—from thirty-five to fifty pounds per ton, and it checked exactly with the calculated torque resulting from the 14 amperes which were used electrically. In other words, I started once mechanically by men hauling on the dynamometer, and then electrically, and they checked very well, running somewhere to 175 to 200 pounds for five tons. Respecting the feasibility of steam as compared with electric traction in case every possible improvement is made, I assumed in the paper I prepared previously on the subject, that the traction coefficient would be the same for the same pull, no matter how exerted. It is so much per ton that has to be exerted. Now the way I took hold was to calculate this very thoroughly—this cumulative load with steam, the coal necessary to be carried, and the water and the surface opposed to the atmosphere in increasing your speed, and I formed a table, which I believe is reliable, showing that at varying ratios for efficiency for electric locomotive machinery, and assuming what we know to be the average efficiency of the steam mechanism at such and such speeds, that you will have an economy greater in the one case or the other, as follows: If you can get ninety per cent. efficiency out of your electric service and have a frequent service—that is, of course, an indefinite term, but I define in my calculation a particular frequency which is not excessive as compared with the local traffic, say, of the New York Central road—with such a frequency with ninety per cent. efficiency and at twenty miles an hour, the electrical propulsion is slightly more economical than steam propulsion. Now, as you increase your speed the relative value of the electrical propulsion increases enormously, and finally, at high speed, say 120 miles, your electrical propulsion is something like six times more economical than steam propulsion, considering steam propulsion even possible. But it is not possible to propel ordinary trains by steam at 120 miles for any length of line worthy of consideration, because the amount of coal and water that you are required to carry has reached a quantity that would require two or three tenders to take care of. You can readily see that it is a cumulative thing. Every pound of coal you put in requires some more coal to be burnt to pull that pound and you have to carry it, and you have water, so that when you get to the high speeds it is out of the question, and we have nothing to look for at very high speeds, save electrical propulsion. But if we come to comparatively low speed service and a comparatively infrequent service, the steam will beat us. [Applause.]

Mr. Pierce:—Do I understand Mr. Crosby then to mean that for heavy freight service steam would be more economical than electricity?

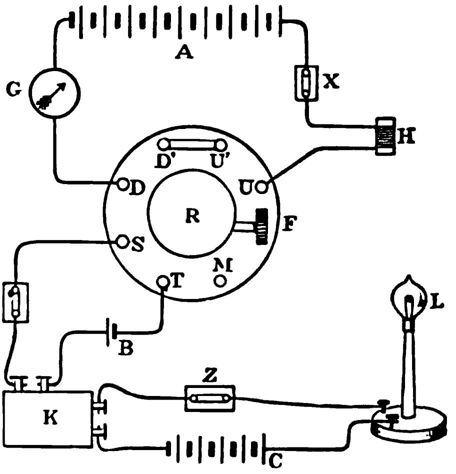
Mr. Crosby:—Yes; I think for heavy freight service, unless its frequency is far beyond anything we have to-day, it can be carried on more economically by steam than by electricity.

Mr. Sprague:—I heartily agree with Mr. Crosby in his opinion regarding the freight service—that it will for a long time be more economically carried on by steam, than by electricity; likewise long trunk transportation. You must understand that electric transmission is going to bring up a new system of train operation, and train despatching.

AN AUTOMATIC LAMP LIGHTER.[1]

BY SHELFORD BIDWELL.

In illustration of a paper on selenium, read at a recent meeting of the Physical Society, I exhibited an electric lamp which was connected with a selenium-cell and a relay in such a manner that the lamp was automatically turned on in the dark and extinguished by the action of light. The details of the arrangement were, however, not described, and I propose to give here a few particulars for the assistance of those who may wish to repeat the experiment.



Selenium Automatic Lamp Lighter.

A scheme of the connections is shown in the annexed diagram. It will be seen that there are three circuits. The first includes a battery A, of 24 small Leclanché cells, the selenium-cell H, and the magnet coils of the relay R. A Post-office tangent galvanometer G, capable of measuring milliamperes, is a convenient but not indispensable adjunct. In the second circuit is a Leclanché cell B, one pole of which is connected through the terminal T with the tongue of the relay R, and the other through the magnet-coils of the electro-magnetic switch K, and the terminal S, with one of the platinum stops of the relay. The third circuit contains the lamp-battery C, the incandescent lamp L, and the tongue and stop of the electro-magnetic switch K. The three simple switches, X, Y, Z, are useful for breaking any of the circuits.

The selenium-cell H has a resistance in the dark of about 50,000 ohms, which is diminished to one-half, or less, by the action of diffused daylight, or by the light of an ordinary gas jet at a distance of 1 foot. The relay R is a "standard relay," as used in the Postal Telegraph service. Its tongue, connected with the terminal T, oscillates between two adjustable platinum stops, which are connected respectively with S and M. (For brevity we will call these the S stop and the M stop.) It contains four magnet-coils

---

1. *Nature.*

which, as the instrument is sent out by the manufacturers, may be connected either all in parallel or two in series and two in parallel. For the present purpose it is desirable that the coils should be joined up all in series, thus greatly increasing the sensitiveness of the instrument to small currents at an immaterial sacrifice of rapidity of action. This can only be done by altering the permanent connections underneath the stand of the relay. The terminals D′ and U′ are joined to each other by a brass strap. Care must be taken to join the terminal D to the zinc pole of the battery. The electro-magnetic switch K is simply an ordinary electric bell relay; it is used in order to avoid passing a strong current through the delicate relay R. The lamp L is an 8-volt lamp of 5-candle power. The battery C consists of 5 bichromate or Grove cells; secondary cells, if available, would of course be much better.

The connections being made as above, it only remains to adjust the relay. The platinum contacts must be clean and smooth; those in my instrument are occasionally cleaned with a watchmaker's "dead smooth" file, and then rubbed with a bright knitting-needle. The two stops are screwed up until there is only just room for the tongue to move between them. The milled head F, is first turned clock-wise, so as to make the tongue press against the M stop, and then (the selenium cell being in the dark, or only feebly illuminated) it is slowly and cautiously turned counter-clockwise, until the tongue passes over to the S stop, which causes the lamp to be switched on. If, now, the selenium cell is exposed to a sufficiently strong light, the tongue moves back to the M stop, owing to the increased current through the magnet coils, and the lamp goes out. It is possible to adjust the relay so that the lamp is lighted automatically whenever the external illumination falls below any desired degree of intensity, and the adjustment, when once properly effected, will remain perfect for days or weeks together.

The selenium cell is made by winding two fine copper wires, which serve as electrodes, very close together around a slip of mica, one surface of which is afterward coated with a thin film of selenium. I have given full instructions for the manufacture of these cells in *Nature*, vol. xxiii., p. 58, and need not repeat them here. The cell used for the lamp experiment, measures 2¼ inches by ¾ inch; the gauge of the copper wires is No. 36, and each wire makes 20 turns to the inch. The resistance of the cell in the dark is about 52,000 ohms.

The experiment may be shown by placing the cell near a window, and closing the shutters, when the lamp immediately lights up, going out again as soon as the shutters are reopened. When daylight is not available, the effect may be exhibited in a scarcely less striking way by alternately screening and exposing a gas burner placed at a distance of a foot or two from the selenium, or by turning the gas up and down. The following test illustrates the sensitiveness of the arrangement. The relay was adjusted so that the lamp circuit was just closed when a standard candle was burning at a distance of 7⅛ inches from the selenium-cell. The candle was moved slowly towards the cell, until the distance between them was reduced to 6⅛ inches, when the increased illumination caused the lamp circuit to be broken. The candle was then moved back, and when the distance was once more 7⅛ inches, the circuit was again closed. By moving the candle backwards and forwards over a range of about 1 inch, the circuit could be alternately closed and broken as often as desired. The extreme difference in the strength of the currents passing through the selenium under these changes of illumination was shown by the galvanometer to be rather less than 0.1 milliampere.

Though the apparatus does not at present claim to be anything more than a pretty scientific toy, it is possible that it may turn out to be of some practical utility. To demonstrate its capabilities, I one day left the selenium-cell near the window, with the batteries joined up. At about 4 P. M., just when reading was becoming impossible through failing daylight, the lamp (which I had in fact forgotten all about) was automatically turned on.

College Notes.

LOWELL INSTITUTE, BOSTON.

In 1889 an application was made to Augustus Lowell, trustee of the Lowell Institute, for funds to pay lecturers in several evening courses at the Wells Memorial Workingmen's Institute. He provided funds for the purpose, on condition that the lectures were free, and that the Lowell Institute received full credit in all reports, etc., of the institute. It was then decided to have courses as follows for the winter of 89–90: Carpentry, Elements of Mechanism, Practical Electricity, Steam and Steam Engine.

The course in electricity was the most successful. The first lectures were given by different men, and the interest began to wane. Then Prof. Wm. Puffer, of the Massachusetts Institute of Technology, gave the last six, and made a success of the course. These lectures were very successful considering that there was no power to show the apparatus.

This winter Prof. Puffer gave the entire course of fifteen lectures, and had an average attendance of 106.

The professor treated theoretical and practical electricity generally, taking up all the subjects of the day.

When this course came to an end, a petition was circulated among the men, to see if the professor could give a supplementary course, the cost of which would not be beyond a working man.

The institute offered a room, heat, light and power (I omitted to mention that power had been introduced, and made the lectures more interesting as apparatus could be shown), free of charge on condition that full credit was given to the institute for the class, as an outcome of the lectures given there.

This generous offer was accepted and a course of ten lectures was decided on. Tuesday evening commencing March 10, 1891. The cost for the course of lectures will be $2.50 a person, payable in advance. The professor will take up electric lighting, power, railway, accumulators, etc., in detail. At present there are 25 in the class, and this number will be increased to about 40.

Literature.

First Principles of Electrical Engineering. By C. H. W. Biggs, Editor London *Electrical Engineer*. London, 1890, Biggs & Co. New York, The D. Van Nostrand Company. 5 x 7 inches, 208 pages.

The general tendency of the age towards radicalism, now playing so prominent a part in politics and religion, is felt even to the domain of science, and in the methods of teaching it. An impression has gone abroad that the heads of our youths are being crammed with a variety of information which leaves them in a hopeless condition of repletion and impractibility when they enter the actual work of life; and the cry has been heard that the teaching which is to do the most good in the end should be more practical in its nature, involving less of the higher mathematics, and the information should be generally so placed before the student that the process of assimilation, instead of being a difficult one, shall, as it were, be natural and involuntary.

Mr. Biggs has written the little work before us, on these modern lines, in which attempt, we are free to confess, he has succeeded admirably. The book is not intended for electrical engineers, but for those who intend to enter the profession, and the method of treatment throughout is to give the "principles" in as few words as possible, but to bring out in bold relief their applications. The author passes, after a short introductory on the nature of electricity—which, we may say in passing, he designedly does not attempt to explain—to the conductive circuit, explaining and demonstrating the nature of resistance, defining the ohm and Ohm's law, and then applying analogous reasonings to the static inductive and magnetic circuit.

The author then passes to the methods of practically producing electrical pressure or difference of potential, starting with the static induction machine, the chemical battery, the modern dynamo and transformers. In explaining the subject of the field magnets of dynamos, their strength and their method of calculation from given data, the author has inaugurated a style which it is to be hoped will be more frequently followed to the advantage of the student. His explanations, while elementary in their nature, fully cover the ground and can leave no uncertainty in the mind of the student as to the meaning of the terms and the methods of their application to actual practical work. By means of very simple practical examples, the strength of the magnetic inductive field in dynamo electric machines is worked out, denoting the strength both in lines per square centimetre and in Kapp lines, to which latter the author strongly inclines for practical reasons.

In this connection the author throws out a hint which is worthy of consideration. He suggests that proper authorities should issue sets of magnetic resistances like those of inductive resistances. Manufacturers could then take a piece of iron from the bulk, of certain length of sectional area, wind it with a certain number of ampereturns and balance it against a standard resistance, issuing the bulk of iron as having a certain magnetic resistance per unit length and unit section. This is evidently on the lines of the application of the magnetic bridge, which has not yet, unfortunately, received the attention which its importance deserves. Passing from the field magnets, the author takes up the armature and treats it in a similar manner, showing how the electrical pressure generated in the armature is dependent upon the density of the lines of force cut by the conductor, the velocity with which it revolves and the number of turns through which the lines of force are looped in a given time, illustrating by a practical example the method of application of these principles. The work concludes with a chapter on methods of electrical distribution and on the method of making simple, every-day measurements by the use of the galvanometer, the Wheatstone bridge, ammeter and voltmeter.

As a preparatory course of reading and study, the work will be found not only valuable, but interesting, the style employed being such as to at once enlist the sympathy of the reader who is seeking light on a subject which has on many occasions been enshrouded in mist and mystery, and as such we can heartily recommend it to the many who are taking up this study with a view to future occupation.

Home Correspondence.

PITTSBURGH.

Opposing the Postal Telegraph Lines.—Electric Cars for Funeral Processions.—$100,000 Bouds for the Allegheny City Plant.

THE Postal Telegraph Co. is meeting with opposition in Warren, Ohio, in building its new line from New York to Chicago via Pittsburgh. Some of the landowners in that vicinity are opposing the construction of the line, and the Postal Telegraph Co. has taken the case into court. It has been found that the point at issue has never been decided in the Supreme Court of Ohio, and it will therefore be taken there to establish a precedent. All work on the new line, however, has to be stopped in the meanwhile and a good deal of delay is caused in consequence.

The stockholders of the Suburban Rapid Transit Electric Railway Co., of this city, held a meeting lately for the purpose of formulating a plan to have a couple of new cars built for their road, which are to be used exclusively for the carrying of funerals. There are seven cemeteries located along the line of the company's road and on the average five funerals pass over that route every day. The company now intends to have the cars equipped with electric motors, and they are to be known as the funeral cars.

Last Wednesday night Allegheny councils passed an ordinance providing for the issuance of $100,000 worth of bonds to pay the cost of the city light plant, which was put up last year by the Westinghouse Electric and Manufacturing Co.

There is a bill now pending before the State Legislature of Pennsylvania, which has the object of reducing the rates for telephones. Yesterday all the companies were invited to appear before the committee. The Pittsburgh manager of the Bell Telephone Co. spoke at length against the bill. The burden of his remarks was that his company would not be able to continue in business if the new bill were passed.

PITTSBURGH, March 10, 1891.

Society and Club Notes.

MR. DOBBIE ON ARC LIGHTING BEFORE THE BROOKLYN INSTITUTE.

The monthly meeting of the department of electricity of the Brooklyn Institute was held in the lecture room of the Young Men's Christian Association, Fulton street, on Friday evening, Mar. 6, an audience of nearly two hundred being present.

President Hamblet introduced Robert S. Dobbie, of the Edison General Electric Company, who gave an excellent address on "Arc Lighting," following it up historically from the very first experiment made by Sir Humphrey Davy, down to the arc lights of to-day.

Mr. Dobbie also told of the numberless experiments which have constantly been made since the first production of carbons for arc lights, in 1846.

Mr. Dobbie showed, by an ingenious arrangement, how the carbons of an electric light burn together, forming the arc. It was a successful as well as novel experiment, and brought forth considerable applause, as did the lecture as a whole.

THE AMERICAN STREET RAILWAY ASSOCIATION.

The list of the committees to report at the tenth annual meeting of this Association to be held in the city of Pittsburgh, Pa., the third Wednesday in October (the 21st,) 1891, is completed, and is as follows:

A Perfect Electric Motor.

H. A. Everett, Secretary, East Cleveland Railroad Company, Cleveland, Ohio.

A Year's Progress of Cable Motive Power.

J. C. Robinson, formerly vice-president, Los Angeles Cable Railway Co, Los Angeles, Cal.

Public and State Treatment of Corporations, No. 3.

G. Hilton Scribner, President Central Park, North and East River Railroad Company, New York City.

The Dependent—Overhead or Underground—System of Electric Motive Power.

George W. Mansfield, Director, Attleboro, North Attleboro and Wrentham Street Railway, Attleboro, Mass.

The Independent—Storage or Primary Battery—System of Electric Motive Power.

Knight Neftel, Electrician, Lancaster City Railway Company, Lancaster, Pa.

NEW YORK ELECTRIC CLUB.

The regular meeting of the Club to nominate officers for the year beginning May 1, 1891, will be held at the Club House, 17 East 22nd st., Tuesday evening, March 17, at 8 o'clock.

EXECUTIVE COMMITTEE MEETING OF THE N. E. L. A.

At the executive committee meeting of the National Electric Light Association held at the New York Electric Club on March 14th, Mr. Allen B. Foote requested as a personal favor that his resignation as secretary and treasurer be accepted, to enable him to devote more time to work in connection with the electrical department of the U. S. Census and his economic studies. He reported $1,294.54 in bank and not one dollar of unpaid claims against the Association. Mr. Foote's resignation was accepted, to take effect April 1, 1891. Pres. Huntley nominated Mr. John W. Beane as secretary and treasurer. The nomination was confirmed.

Tuesday, Wednesday and Thursday, August 25, 26 and 27, 1891, were fixed as the dates of the next convention to be held at Montreal, Canada. The headquarters of the Association will be at the Windsor Hotel. It is probable that arrangements will be made for a very large electrical exhibit to be open for the entire week.

The following committees were appointed:—

1. *Committee on Amendments to the Constitution.*—Geo. B. Shaw, chairman; Marsden J. Perry, Hon. E. A. Armstrong.
2. *Committee on Underground Conduits and Conductors.*—M. J. Francisco, chairman; T. Carpenter Smith, A. M. Robertson, John A. Seely, M. D. Law.
3. *Committee on Finance.*—John A. Seely, chairman; E. F. Peck, N. H. Fairbanks.
4. *Committee on Transportation.*—Mr. Edgar, Montreal, chairman; C. O. Baker, C. A. Brown, Henry D. Stanley, A. J. Corriveau.

Mr. John W. Beane, the new secretary of the National Electric Light Association, was educated at the United States Naval Academy and graduated in 1873. He then entered active service and served as an officer in the Navy six years. He then resigned to enter business in civil life. In 1885 he became identified with *The Electrical Review* as one of its editorial staff. Later, he accepted the agency of the Mather Electric Co. for the Middle States. When the Tucker Electrical Construction Company was organized, Mr. Beane became interested in it, and was elected its general manager. In 1890 he accepted a special commission from the United Edison Manufacturing Company in connection with their business in New England, which was terminated recently.

THE NICHOLSON ELECTRIC HOISTING AND CONVEYING MACHINE CO.

An electric hoisting and conveying machine, the invention of Ezra Nicholson, of Cleveland, Ohio, has been in operation during the past few weeks in Cleveland, and has been examined by prominent iron ore and coal men and pronounced an unqualified success. The designing and construction of the plant has been in charge of W. P. Williams, a member of the American Society of Civil Engineers. Mr. Williams and Mr. Nicholson have patented several different systems for the hoisting and conveyance of bodies by electricity, and will shortly organize a company to commence the manufacture of plants for coaling terminals and general work.

This new invention is especially adapted for economic use in loading and unloading vessels or cars of iron ore, coal, or general merchandise, and to convey the load to any desired point. A 30 h. p. Rae electric motor is mounted upon a light tram car holding suitable hoisting mechanism and the operator riding on this car hoists the load from any desired point and rapidly conveys it to the place of unloading. The presence of the operator always over his work has a great advantage over steam automatic cable systems in present use.

The present work performed by the plant is unloading a vessel of iron ore, hoisting a load of 3,000 lbs. vertically 5 feet per second, then traveling across a bridge 30 feet high and 200 feet long spanning the ore dock, the cross travel being made in ten seconds, and the operator stopping the car holding the bucket and dumping the load at any desired point. Systems have been designed for quarry, rolling mill and contractors' use by Messrs. Nicholson and Williams.

NEW YORK SUBWAYS.

According to President Lauterbach, the subway company built 65 miles of subway last year, but less than five miles were occupied. Seven of the electrical companies have applied, however, to the Board of Electrical Control for more subways, some of which would run under streets recently repaved. New lists are to be prepared showing where the wires can be taken down and put underground, and then other subways may be ordered.

Reports of Companies.

ELECTRIC LIGHTING CONSOLIDATION IN ST. LOUIS.

At a meeting of the Laclede Gas Light Co. on May 2, a proposition will be considered to increase the capital stock from $10,000,000 to $12,000,000, the increase being in common stock. The object of this is to perfect the purchase of the properties of the Missouri Electric Light and Power Co., and of the Municipal Electric Light and Power Co., of St. Louis.

The sum of $2,000,000 was paid for the Municipal, its plants, wires, franchises and contracts. Of this sum $1,500,000 was paid in cash, and $1,500,000 in common stock, worth about $300,000 on the market, or $1,800,000 in all. The floating debt of $600,000 was assumed by the Laclede, making the total about $2,400,000, and about $400,000 of the unsold bonds of the Municipal were turned over to the Laclede, leaving the net cost $2,000,000.

The negotiations with the Missouri Electric Light Company were speedily concluded, the Laclede agreeing to pay $1,100,000 for the plant and to assume the bonded indebtedness, while the floating debt was to be taken care of by the Missouri Company.

THE AMERICAN PROJECTILE COMPANY.

The directors of the Thomson Electric Welding Company have issued a letter to the stockholders of that company in regard to the new Projectile Company. The circular states that in 1889, Lieut. Wm. M. Wood, U. S. Navy, associated himself with the Welding Company and conceived the idea of adopting the welding process to the manufacture of various kinds of shells. A series of expensive experiments had been carried on at the welding factory in the manufacture of both armor-piercing shell for navy use and shrapnel for the army. These experiments resulted in the receipt of substantial orders for these supplies for use in both the army and navy.

As the business of the Electric Welding Company is solely the manufacture of electric welding machines, the directors decided that it was advisable to organize the American Projectile Company, with a capital of $500,000. Two hundred and fifty thousand dollars in the stock of the new company is to be paid to the Thomson Electric Welding Company, for its United States projectile patents and the exclusive use of the welding process for the manufacture of shell in this country. The remaining $250,000 of the stock of the company will be sold at par for working capital.

THE UNION SWITCH AND SIGNAL CO.

At the annual meeting of the Union Switch and Signal Company, one of the eight Westinghouse corporations, the old directors, headed by President George Westinghouse, Jr., were ousted and a new board elected.

The whole thing, which was a tremendous surprise, was accomplished by Secretary A. T. Rowand, who voted the proxies for a new ticket, which included himself.

Mr. Rowand is accused of having voted proxies in direct violation of the wishes and commands of the stockholders who gave him the papers.

The new board consists of Edwin F. Waters, W. Scott Fitz and Sigourney Butler, of Boston; Henry C. Terry and Owen B. Jenkins, of Philadelphia, and G. Shane and A. T. Rowand, of Pittsburgh.

Three prominent members of the old board and defeated ticket are President Westinghouse, his brother Herman S. and Robert Pitcairn, the superintendent of the Pittsburgh division of the Pennsylvania Railroad Company. Steps have been taken, however, to have the election set aside, and Mr. Westinghouse has installed men acceptable to himself.

THE HUDSON RIVER TELEPHONE CO.

The report of the above company shows a net revenue of $51,505.41, plus the surplus of $15,867.71 of January 1, 1890, making an amount on hand of $67,378.14. Out of this four dividends were paid, amounting to $41,208.14, leaving a surplus January 1, 1891, of $26,165, which, with the proportion of Westchester earnings, leaves a total surplus of $49,837.13. The company's resources are $2,078,840.14; liabilities, $2,052,675.14.

It has become essential to secure a permanent location in Albany, and a lot, 21x85, on the corner of Chapel and Maiden lane, has been purchased at a cost of $9,000. Plans are being prepared for a three-story and basement building to cost about $25,000.

DIVIDENDS.

LYNN, MASS.—The Lynn Belt Line Street Railway Company has voted to pay a dividend of 5 per cent. to all stockholders July 1, 1891.

WESTERN UNION TELEGRAPH CO.

For the quarter ending March 31, the net revenues of the Western Union Telegraph Company are estimated at $1,500,000. After deductions for interest on bonds, sinking fund payments, and $1,077,400 for a 1¼ per cent. dividend on the stock, a net surplus of $11,321,137 is figured out. The directors have recommended the payment of a dividend of 1¼ per cent., payable on and after April 15.

ELECTIONS.

IONIA, MICH.—At the annual meeting of the Ionia Electric Company, Directors L. B. Townsend, H. R. Wagar, J. E. Just, C. J. Rumsey, and A. S. Wright were re-elected, and the directors re-elected President Townsend, Vice-President Wagar, and Secretary and Treasurer Just.

PATCHOGUE, N. Y.—At the annual meeting of the stockholders of the Patchogue Electric Light Works the following board of directors were elected: John S. Havens, Jesse C. Mills, Andrew Fishel, George D. Gerard, John H. Mills, Frement Hammond, Edwin Bailey, Nathaniel O. Sweezey, Hallett J. Bishop, Henry Gillette, and Isaac G. Willetts. The officers were elected for the ensuing year as follows: President, J. S. Havens; vice-president, J. C. Mills; secretary, N. O. Sweezey; Treasurer, J. H. Mills; executive committee, H. J. Bishop, G. D. Gerard and J. C. Mills.

Appointments, Etc.

MR. J. ALLAN HORNSBY has been appointed secretary of the Electrical Bureau of the Columbus Fair by Commissioner J. P. Barrett.

MR. W. A. CARY, of the Thomson-Houston Electric Co., has just been made treasurer of the Plymouth, Mass., Electric Light and Power Co., and the Seneca Falls, N. Y., Electric Light Co.

MR. C. H. REYNOLDS.—When Mr. C. H. Reynolds retired from the superintendency of the Omaha electric lines, the motor men and conductors presented him with a handsome diamond pin as an expression of their good will and feelings toward him. The new superintendent, Mr. Stone, has assumed the duties of his office.

MR. WILLIAM H. JONES, for the past eight years manager of the Western Union telegraph office in Lowell, Mass., has tendered his resignation to take effect as soon as his successor can be appointed.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of March 14, 1891, from New York, Boston and Washington; Pittsburgh, March 6.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 10, 1891.

Alarms and Signals :

Electric Railway-Signal. W. W. Rosenfield, 447,906. Filed May 17, 1890.

Adapted to the block system ; provides for giving an alarm in the cab of a locomotive or at another part of a train when it enters upon a block in case a predetermined succeeding block be occupied by a train either moving or stationary.

Electric Railway Signaling Apparatus, E. L. Harrison, 418,081. Filed March 4, 1890.

Adapted to denote at all times the presence or absence of trains upon certain sections or blocks of a railway ; the signal circuits are actuated by the passage of the engine or cars.

Train-Order Annunciator, L. T. Crabtree, 418,125. Filed July 11, 1890.

Adapted to prevent the telegraph operator at any station (unless intentionally negligent) from receiving train-orders until he has set a train-order-signaling device on the track, and to insure the exhibition of such train-order-signals while the operator has in his hands an order received for an approaching train ; enables a train conductor who has been signalled to ascertain without inquiry if an order or orders await his arrival.

Electric-Light Signal, W. R. McCann and S. S. Creider, 447,894. Filed Sept. 8, 1890.

Designed to enable signal lights at several stations to be severally lighted or extinguished from a central station; adapted for service at police stations or at points between telegraph offices on railways to call attention preparatory to communicating information from a central station by telephone, telegraph or otherwise.

Electric Alarm, G. W. Adams, 447,998. Filed June 6, 1890.

Relates to a protective system for buildings, and consists chiefly in the use of two independent circuits between a central station and and the building or buildings to be protected, one an open circuit and the other a closed circuit.

Combined Push and Pull, A. Iske, 418,044. Filed June 27, 1890.

A combined push-button and pull-knob by which either a pressure or a pull will close an electric bell circuit.

Polarized Annunciator, E. P. Warner, 448,169. Filed Jan. 9, 1890.

Consists in providing, in connection with the poles of an electro-magnet, a pivoted permanent magnet so arranged as to hold the shutter or drop while current in one direction is passing and to release it when a current in the opposite direction is passing.

Signal Box, F. W. Cole, 447,869. Filed Dec. 23, 1890.

Adapts to a signal-box, with a train and signal-wheel, a switch for shunting out the signal-wheel and another switch for cutting out the signal wheel, the switches being operated in succession, first to shunt out and afterward to cut out the signal wheel.

Conductors, Conduits and Insulators :—

Coupling for Electric Wires, C. M. Knight and T. Hawken, 447,833. Filed Nov. 20, 1890.

For joining wires end to end.

Conduit for Electric Wiring in Buildings, S. Bergmann, 447,861. Filed Aug. 1, 1890.

Consists in providing a seat, or seats placed at various points, in conduits for interior wiring, adapted to receive a switch and includes details of construction and arrangement of the switch.

Insulation of Electric Conductors, F. J. Nash, 447,896. Filed May 12, 1890.

Claim 1 follows :

An electric conductor insulated by a surrounding bed or layer of insulating material in the condition of an impalpable powder, whereby the particles thereof are packed together so closely as to exclude air and moisture.

Electric Conductor, F. J. Nash, 447,897. Filed May 13, 1890.

Aims to provide a flexible conductor of high insulation. The conducting wire is enclosed in a layer of pulverized insulating material the particles of which are free to move relatively, the insulating material being enclosed in a retaining envelope.

Dynamos and Motors :—

Electric Starting Switch, W. Hochhausen, 447,827. Filed Nov. 26, 1889.

For electric motors ; consists in combining with an electric motor and its main starting switch a secondary switch controlling a resistance or other device for preventing damage to the armature at starting, and an actuating device for the secondary switch operated by the main switch, but having a lost motion so that the resistance or safety device may not be cut out until after some interval of time when circuit has been closed on the motor ; thus enabling the motor to acquire speed and counter electromotive force during such intervals of time.

Alternating-Electric-Current Generator, N. Tesla, 447,921. Filed Nov. 15, 1890.

Claim 1 follows :

The combination in an annular field of force formed by opposing polar faces with radial grooves or serrations and with said poles, of a connected series of radial conductors so disposed with relation to the serrations that while one portion of the radial conductors is passing between the strongest parts of the field, or the points where the two poles most nearly approach, the adjacent or intermediate conductors will pass through the weakest parts of the field, or the points where the two poles are most remote.

Electric Motor, W. H. Chapman, 447,939. Filed July 5, 1890.

A multipolar motor with a series of field-magnet cores arranged in pairs, the two cores in each pair are placed parallel to the axis of revolution and connected together in one piece, but separated from contact with the cores of the adjacent magnet and having their pole ends curved tangentially to a plane at right angles to the axis of revolution in both directions from the centre of each of the cores.

Commutator, W. Hornberger,. 448,040. Filed Aug. 2, 1890.

The commutator section has a side edge protected or strengthened by metal of greater density or hardness.

Lamps and Appurtenances :

Electric-Arc Lamp, H. C. Forgason, 447,767. Filed May 23, 1890.

Relates especially to the cut-out. Provides for bringing the carbons into close contact when exhausted.

Electric-Light Fixture, J. Kintz, 447,832. Filed May 15, 1890.

Design and construction for a bracket fixture.

Method of Operating Arc Lamps, N. Tesla, 447,920. Filed Oct. 1, 1890.

Claim follows :

The method of abating or rendering inaudible the sound emitted by arc lamps supplied with or operated by an alternating or pulsating current by increasing the rate of such alternations or pulsations up to that of the limit of audition.

Electrode for Arc Lamps, A. C. Seibold, 448,084. Filed Dec. 24, 1890.

Provides a holder or casing for the positive carbon, consisting of a metallic tube with an interior diameter freely admitting the carbon; at the lower end of the tube is a removable flat plate in immediate proximity to the arc and having an opening of less diameter than the carbon.

Device for Raising or Lowering Incandescent Electric Lamps, C. F. Reinmann, 448,164. Filed Feb. 8, 1890.

An adjustable suspension device.

Automatic Switch-Board and Safety Cut-Out for Electric Circuits, E. A. Sweet, 448,166. Filed Oct. 22, 1890.

A device for short-circuiting automatically any one of a number of circuits connected in series for electric lighting in case of accident and without disturbing other circuits.

Switch for Incandescent-Lamp Sockets, A. T. Tregurtha, 447,167. Filed Sept. 20, 1890.

Details of design and construction.

Electric Arc Lamp, La M. C. Atwood, 448,107. Filed Oct. 28, 1890.

Relates to the class of lamps employing a motor for moving the carbons ; details of mechanism.

Medical and Surgical :—

Galvanic Apparatus for the Human Body, P. G. Williams, 447,857. Filed June 6, 1890.

Includes a flat battery adapted to be worn upon the person.

Body-Battery and Attachments for the same, J. A. Crisp and G. F. Webb, 448,128. Filed Nov. 21, 1890.

Similar in purpose to the above.

Miscellaneous :—

Electric Switch, J. M. Orford and J. C. English, 447,783. Filed Dec. 19, 1890.

Relates more particularly to switches of the double-pole class ; adapted to make or break contact by a pushing movement.

Electric Switch and Cut-Out, W. Hochhausen, 447,826. Filed Mar, 12, 1889.

Designed to control the flow of current to an electric translating device ; adapted for both manual and automatic operation ; suitable for attachment to ceilings or to in-door apparatus.

Electric Switch, H. T. Clark, 417,867. Filed Jan. 26, 1891.

A quick-acting or "snap" switch.

Current Wheel, W. Stephens, 447,915. Filed Mar. 21, 1890.

A system of current-wheels and floats adapted for the transmission of water power to drive a dynamo.

Electric Door-Opener, L. Bates, 448,110. Filed July 14, 1890.

Adapted to control a pivoted latch through electro-magnetic apparatus.

Railways and Appliances :—

Trolley Carriage and Conductor, C. J. Luce, 447,885. Filed Apr. 4, 4890.

The trolley-carriage is provided with a wheel or pulley above and also one below the wire, a rigid arm pivoted to the carriage at a point between the wheels or pulleys is connected to the roof of the car by a flexible conductor.

Trolley for Electric Railways, M. J. Wightman, 448,172. Filed Aug. 12, 1890.

The trolley arm is provided with a practically universal joint, and a spring tension device tending to move the arm into vertical position, so that the direction of pressure between the trolley and the trolley wire is always in a plane nearly parallel to the wire. The invention also includes special devices for suspending the conductors, and details of frogs, turnouts and junctions.

Trolley for Electric Railways, M. J. Wightman, 448,173. Filed Aug. 12, 1890.

A trolley arm having a practically universal joint is provided with a gear to prevent the twisting of the arm. Invention includes details of line construction and is adapted especially to a two wire or double trolley system.

Telegraphs :—

Railway-Car Telegraphy, W. S. Cook & M. C. Cook, 447,943. Filed April 21, 1890.

A system of telegraphing to or from moving trains in which actual contact is made with overhead conductors.

Telephones and Apparatus :—

Combined Annunciator and Telephone System, J. C. Francis, 447,768. Filed Nov. 5, 1889.

A combined annunciator and telephone system adapted for use in hotels and other buildings and enabling the ordinary annunciator to be used without an expensive change in including a telephone circuit.

Induction-Preventive for Telephones, T. F. Wright & E. G. Wilson, 447,858. Filed July 28, 1890.

Adapted for attachment to a receiving telephone. Claim 5 follows :

The combination with a telephone receiver and the diaphragm thereof provided with a central perforation of an induction preventive comprising a hollow casing provided with perforations, a tube extending between said perforations, a spool located within said casing, and a metallic coil wound upon said spool, one end of which is embedded in the spool and the other terminates opposite the centre of the perforation in said diaphragm.

Telephone-Toll Apparatus, W. Gray, 448,024. Filed April 5, 1888.

A "nickel-in-the-slot" apparatus.

Automatic Telephone-Exchange, A. B. Strowger, 447,918. Filed March 12 1889.

Claim 1 follows :

In a system of telephone, telegraph, or other electrical exchange, the combination, with a series of wires leading to different stations in the system and having their ends insulated and held in curved rows, of a contact needle supported at the axis of the rows, mechanism for moving the needle from row to row, mechanism for moving the needle along the row, magnets for actuating said mechanisms, and wires leading from a sub-station for conducting electricity to energize the said magnets.

Apparatus for Intensifying Electrical Undulations, J. C. Ludwig, 448,153. Filed Sept. 10, 1889.

A telephonic repeater. Employs in connection with a telephone receiver, a local battery circuit with its poles adjacent to the diaphragm, loose granular particles of carbon or other conducting substance placed on the diaphragm to complete the local battery circuit, and one or more secondary circuits interposed between the line wire and the bobbin of the receiver.

Moore Electric Mfg. Co. will remove May 1, to corner Thirteenth and Hudson, this city, which will give them four times their present accommodations. They will carry on the manufacturing of electrical apparatus and supplies, branch blocks, sockets, cutouts and the sale of larger apparatus and wire.

Mr. James P. Francis will, it is said, be appointed superintendent of the Southern Massachusetts Telephone Co., of New Bedford, in place of Mr. Moses E. Hatch, whose feeble health compels him to retire.

THE PATENT CENTENNIAL AT WASHINGTON.

The committee in charge of the Patent Celebration, to be held in Washington, on the 8th, 9th and 10th of April, announce that in view of the limited seating capacity of the largest public hall in Washington, it has been found necessary that admission to the public meetings, at which addresses will be delivered by distinguished speakers, will be by ticket only. This rule will also hold for the public reception to be given at the patent office and for the excursion to Mount Vernon. Persons desiring to attend the meetings and participate in the reception and excursion should make application at once to J. Elfreth Watkins, secretary of the executive committee, 811 G street, N. W., Washington, D. C.

MOTORS FOR PRINTING OFFICES.

There is a marked appreciation of the electric motor in printing offices, where its ability, if of good design and construction, to stand up under severe strain and to occupy little floor space, has often proved of the utmost advantage to the user. The favor enjoyed by the motor is seen in the fact that it is being adopted for a very large number of new offices. Thus, the Lancaster, Pa., *New Era*, in occupying a handsome building erected specially for its work, has bought from the Elektron Manufacturing Co., of Brooklyn, a 20 h. p. Perret motor, which will not only run the Goss newspaper press, but will operate two or three smaller presses, the wetting machine, the freight elevator and the stereotyping plant. This is no small job for one modest motor, but the Perret will stand it, and come up smiling. A 10 h. p. Perret motor has also been put in to run the *New Era* job printing office. One of the reasons, the paper says, influencing the purchase of these two motors was the fact that they run at such a moderate speed as not to require countershafting to reduce the speed of the main shaft.

Another paper that is making a move is the veteran and vigorous *Commercial Advertiser*, which has lately afforded electricians and electrical engineers the best opportunity to state their opinions and ideas that they have ever had from a daily paper. The *Commercial* will occupy new quarters on Park Row about April 15, and will put in a 20 h. p. Perret motor to run its Hoe presses. Mr. Harold Godwin, the editor, has given this matter his personal attention, and would be satisfied with none but the best.

NEW YORK TRADE NOTES.

Bateman & Pollard.—At a dinner given by Mr. Isaac Stern, 835 5th ave., last week, a novel electrical display was provided by the above firm and formed a unique part of the decorations. Here and there interspersed among the floral decorations were 4 c. p. lamps covered by varied-hued silk hoods, the effect being very striking. The electricity for this display was obtained from accummulators located beneath the table. The affair was a pronounced success and Messrs. Bateman & Pollard feel very much gratified. This firm is at present installing a 1,200 light plant at the Jewish Temple, Bethel; a complete electric light plant of 300 lights including boilers, engines, dynamos, storage batteries, etc., at the residence of Mr. J. B. Newton, Tarrytown, N. Y., and the central station at Schroon Lake in the Adirondacks, for Mr. H. B. Parshall, of this city, to light up Taylor & Sons' hotel and 15 summer cottages, including Mr. Parshall's summer residence. This plant is also furnished with electric motors for pumping water from a spring to a reservoir. Another feature of this plant is a weather vane up in the mountains, recording in Mr. Parshall's residence in the valley below. Mr. Parshall is also fitting up a pleasure launch for use on the lake with electricity as a motive power.

Mr. A. G. Goldmark, of Wallace & Sons, 29 Chambers street, this city, has just returned from an extensive trip through the South and Southwest, and reports the outlook for business in the railroad line as assuming a condition of things which will result in a great deal of construction being done during the coming summer.

Mr. G. R. Turnbull, general manager Butler Hard Rubber Company, 33 Mercer street, this city, has recovered from a severe illness, and is now back in the office.

Taylor & Sons, 39 Dey street, report the sales of their battery as very flattering, and they are reaping the advantage of having at last got a good and substantial primary battery. The battery is so made that its solution, should it happen to be spilled on carpets, will not destroy them.

Mr. W. D. Baldwin, general manager Otis Elevator Company, has returned from a trip to Chicago and the West, which he visited on behalf of the Otis Elevator Company.

The Crescent Insulated Wire and Cable Company, of Trenton, N. J., have lately been organized and are in the field with a superior make of seamless rubber insulated wires and cables. They will use nothing in the manufacture of their wire but the highest grade of Lake Superior copper and fine para rubber, and their manner of treating the caoutchouc in their compounds is such as to secure the highest degree of insulation resistance. Their factory is thoroughly equipped and they will no doubt get a good share of the business in this line.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Advertising is the absolute pre-requisite to the sale of goods."

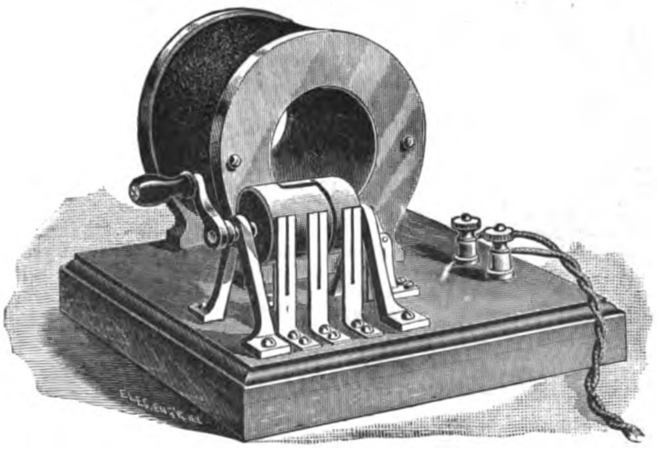
THE BERLIN WATCH DEMAGNETIZER.

BY

Jas Jones &

For a number of years experiments have been going on to perfect a demagnetizer for watches, and numerous contrivances have been the outcome of this work. The simplest of these is that made up of a number of horse shoe magnets, crossed at their curves, and attached to an upright rod, which runs through an opening in a brace mounted upon a standard. The rod is employed to revolve the magnets, and this operation brings to whatever is put before them, first one pole, and then the other, reversing the charge as each point comes to the object. This so-called demagnetizer is in reality not much more than a toy, for it takes out very little magnetism, but affords the operator some amusement. It has in it, however, the principle upon which a demagnetizer for practical work is built.

Such an instrument is that shown in the accompanying engraving, which is the invention of C. F. Berlin, who spent considerable thought, and experimented broadly to bring it to a useful form.



The Berlin Watch Demagnetizer.

It consists of a demagnetizing chamber, about which is wound a coil of wire. The commutator is provided with an operating handle attached, having two dead points and two opposite insulated plates, and four brushes; two of the latter connected with the coil, and two with a pair of binding posts, through which the current is brought to the demagnetizer.

The object to be demagnetized is placed within the demagnetizing chamber, the current having been turned on, and the commutator is revolved rapidly, causing a current to alternately pass in opposite directions through the coil. A few seconds of this operation suffices to do the required work, the object being gradually withdrawn from the coil.

As first designed by the Berlin Demagnetizer Co., the coil was made up by rivetting the proper size of sheet fibre into two wooden standards forming the ends upon which the wire was wound. A strap key was used to put on the current, as it was found necessary to have some means of positively opening the circuit after the operation. Where a key was not used the operator frequently left the current on, and the coil necessarily suffered.

The company has lately given to the firm of J. Jones & Son the sole agency for its now popular instrument, and they have made considerable improvement in it. The key has been done away with, and in its place is used a spring switch of the same principle as that in the old magnetos. The commutator, when operated, is pressed in against the switch bar, and must be held so to receive the current.

The spool is now made of rubber, the wire being covered with a sheet of velvet. This is mounted in two nickeled brass standards, and the whole mechanism is placed on a nicely moulded base. The binding posts are also improved, having knobs on their screw tops, holding the thumb screw portions on, so that they cannot be lost.

T. M. FOOTE REGULATOR CO.

The above company have removed from 271 Franklin street, Boston, to 952 Exchange Building, that city. Their works are at Ashland. Their Western agents are Chandler & Littlefield, 40 Marine Building, Chicago.

SAMSON CORDAGE WORKS.

The Samson Cordage Works, of 164 High street, Fort Hill Square, Boston, Mass., are to remove on April 1, to new offices at 115 Congress street, that city, where they will be pleased to receive or hear from all their old friends in the electrical field.

THE PAGE BELTING COMPANY.

This company manufacture in their extensive works at Concord, N. H., all the staple grades of leather belting, making specialties of wide main belts, particularly for electric plants, and also of a special grade of single belting, which they call their "Crown Extra." During the past year they have added to their specialties for electric work, their Acme link belts, of which they have sold a large number, some of them being put to very hard work, and running at considerably more than a mile per minute with the very best of service. They also report large and increasing sales in their double flat dynamo belts.

This establishment now has stores in Boston, Chicago and San Francisco, and at No. 16 Dey street, New York, where they have a complete stock of staple and special grades of belting, including lace leather, both raw hide and tanned.

"THE BEST," "SUPERIOR TO ALL OTHERS."

All who contemplate purchasing a medical battery should read the following late extracts from the daily business letters received by Jerome Kidder M'f'g Co., the old established firm at 820 Broadway, New York.

L. Dowse, M. D., writes from Petoskey Sanitarium, Petoskey, Mich., March 3rd, 1891: "Have used your batteries for four years and think them the *best out*. Have an almost new —— battery I would exchange for anything in shape of a Kidder." W. H. Hoag, Esq., of Amsterdam, N. Y., writes, Feb. 10th, 1891: "I have used your battery for the last six years, it is *the best*. Would not do without it for twice what it cost." And J. H. Mosely, M. D., of Tomah, Wis., writes under date of Feb. 12th, 1891: "I have had a varied experience with electric batteries, but yours prove *far superior to all others* in the treatment of chronic and acute diseases."

THE LUNKENHEIMER BRASS MFG. CO.

This company announces the purchase of the entire plant of the Porteous Brass Mfg. Co., of Cincinnati, O., and the removal of the machinery and tools to its new addition at Nos. 11 and 13 East Eighth street, in that city. The company is in excellent condition, and, notwithstanding extremely sharp competition, has been again compelled to enlarge its factory.

B. F. STURTEVANT & CO.

A finely illustrated 200 page catalogue of blowers, heating and drying apparatus, portable forges, engines, etc., has just been issued by the B. F. Sturtevant Co., Boston, Mass. It is devoted principally to the general line of goods and method of introduction, as special catalogues are published, relating to the different departments of work. The value of the catalogue to engineers is well voiced in the "Introductory" from which we quote: "The first comprehensive and authentic tables and diagrams relating to the action of the air under pressure, and to the speeds, pressures, capacities and powers required upon all classes of blowers were published in our celebrated catalogues of 1870 and 1873. The information and tables therein contained have formed the basis of all computations of the movement of the air by fans, and have been extensively copied, but not originated by other manufacturers. The constant demand by engineers for these tables led to their careful revision and the introduction of much new material, and they are here presented as the only authentic data relating to fan blowers." The catalogue bears marked evidence of the prosperity of this firm, and of its thorough acquaintance with the branch of engineering in which it is a leader.

SOLDERING SALTS

It will interest those who use soldering salts to learn that The Electrical Supply Co., of Chicago, has decided to handle hereafter, only chemically pure zinc chloride, the commercial article having proven unsatisfactory in some cases. The pure material is readily distinguished by its whiteness and superior strength.

TRUEX & VAIL.

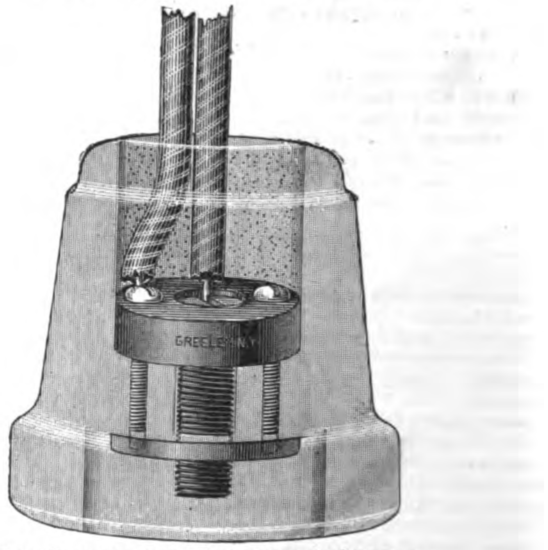
A partnership has been formed by C. R. Truex and W. A. Vail, under the name of Truex & Vail, with headquarters at 44 Broadway, this city. Both gentlemen have had a long experience in the electrical field. They will act as general sales agents for the Accumulator Co, the Electro-Dynamic Co. and the Walker Electric Co, and will handle Edco dynamos and motors, switches, Walker recording ammeters and voltmeters, direct reading ammeters and voltmeters, storage batteries, etc. These specialties constitute an admirable line and are already well known to the electrical profession and trade. The firm are also prepared to furnish electrical supplies and do general construction. For the specialties named, they have secured the exclusive selling agency in New York, New Jersey and adjacent territory.

ROBINSON RADIAL CARS.

Mr. H. A. Everett, the secretary and treasurer of the East Cleveland Railroad Co., writes us that they have purchased a long Robinson radial truck car, which will be between 32 and 33 feet long, and which they hope to get running in a few days.

THE CARTWRIGHT WATERPROOF SOCKET.

AMONG the many new and approved appliances for electric light work that are constantly being brought out by The E. S. Greeley & Company, is a thoroughly waterproof socket, which is illustrated in the accompanying engraving, and which seems to leave little to be desired in the way of a fixture of this kind.



THE CARTWRIGHT WATERPROOF SOCKET.

It is the invention of a practical as well as a theoretical electrician, whose name the socket bears, it being called the Cartwright Waterproof Socket, and has the following distinct features: The porcelain itself, which forms the shell of the socket, instead of being the common porous article, merely glazed over, is a thoroughly vitrified substance, completely impervious to moisture. The metal parts are fastened to the porcelain frame in a workmanlike manner and do not depend for their security upon the sealing compound. The sealing compound itself is of a quality that will stand a zero temperature without deterioration and at the same time will endure the heat that results from a 3 ampere lamp, without softening.

When it is considered that the device is designed simply to meet the requirements of lamps of ½ to 1 ampere capacity, the large margin allowed will be better appreciated.

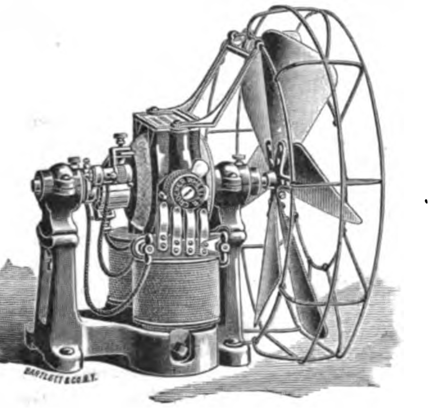
The Cartwright Waterproof Socket is made in three patterns to accomodate lamps of the Edison, Thomson-Houston and Westinghouse types. They are made, as shown in the illustration, with rubber insulated terminal wires projecting several inches from the shell to admit of rod connections.

THE GORHAM MANUFACTURING CO., silversmiths, of Providence, R. I., have issued an exceedingly tasteful little brochure by Mr. Scott A. Smith, on "The Source and Nature of Electricity and its Application to the Electro-Plating Process." The book consists of brief notes, each of which enters into a simple statement of facts or the explanation of phenomena. There are some pretty cuts and a complete index. A great many members of the National Electric Light Association visited the Gorham works during the Providence Convention, and will remember how scientifically the processes mentioned in this pamphlet were carried out. The company has been making solid silverware since 1831, and plated ware since 1865.

THE CROCKER-WHEELER ELECTRIC FAN.

The small electric fan combination is a device which has been improved upon until it has now reached a very high state of excellence. The present style made by the Crocker-Wheeler Company, of West 14th and Washington streets, is shown in the accompanying illustration, and is so arranged that no external resistance is necessary to regulate the speed of the fan, the motor being wound in such a manner that, by simply turning a switch, its speed may be reduced one-half.

These machines are made in three sizes, for use in private houses, small halls, etc., and also in a number of larger sizes up to, and including, ventilating wheels, and exhaust fans 60 inches in diameter for large public buildings.



¼ H. P. Crocker-Wheeler Fan Motor

QUEEN & CO.'S INSTRUMENTS.

The ammeters and voltmeters of the "Magnetic Vane" type made by this firm are meeting with great favor for central stations and isolated plants. They are accurate, contain no permanent magnets and may be left in circuit continuously. Special instruments for any current or E. M. F. are made to order by Queen & Co.

The following testimonials attest the merits of these instruments:—Robinson & Cary Co., St. Paul, Minn. "The magnetic vane ammeters and voltmeters which we have had from you have been entirely satisfactory." Southern Electric Co., Lynchburg, Va. "All the magnetic vane instruments purchased from you have given absolute satisfaction as commercial instruments, and have shown up remarkably well in laboratory work of a general character." Edison General Electric Co., New York. "They have given us very excellent satisfaction, and it affords us pleasure to recommend these instruments." New York and Pennsylvania Telephone and Telegraph Co., Elmira, N. Y. "The magnetic vane ammeter "138," purchased of you, is giving entire satisfaction. This ammeter is in daily use in our testing department, and has always been found reliable and accurate."

THE HUB LINE WIRE

This is a new waterproof wire recently brought out by the Eastern Electric Cable Co., of Nos. 61–65 Hampshire street, Boston. It is known as the "Hub" line wire. The rubber covering is the same as that used on the celebrated Clark wire, made by this company, and over the rubber is a double braid coated with "Clark's patent compound," which makes it very strong and durable. The outside coating being composed largely of a mineral wax, is absolutely weatherproof, and, if subject to chafing, takes a fine, smooth polish.

In a test of this wire at Buffalo, N. Y., the wire was immersed for 24 hours, and dried for 14 hours, alternately for 93 days. The insulating covering was wound for the space of one foot with bare copper wire, the ends of which were attached to a tangent galvanometer, and a current of 1,500 volts pressure passed through the Hub line wire. The galvanometer showed no deflection, thus indicating absolute insulation.

THE RIKER ELECTRIC MOTOR CO.

The above company, of 45 and 47 York street, Brooklyn, are now feeling the rush of spring orders, and with the present week have begun to run night and day. They are not only building their well-known slow speed multipolar motors, but are experiencing an active demand for dynamos from 8 lights up to 350. The shops are crowded to their utmost capacity, and Mr. Riker has no complaint to make of the dullness of the season.

A PAMPHLET ON SCHIEREN BELTINGS.

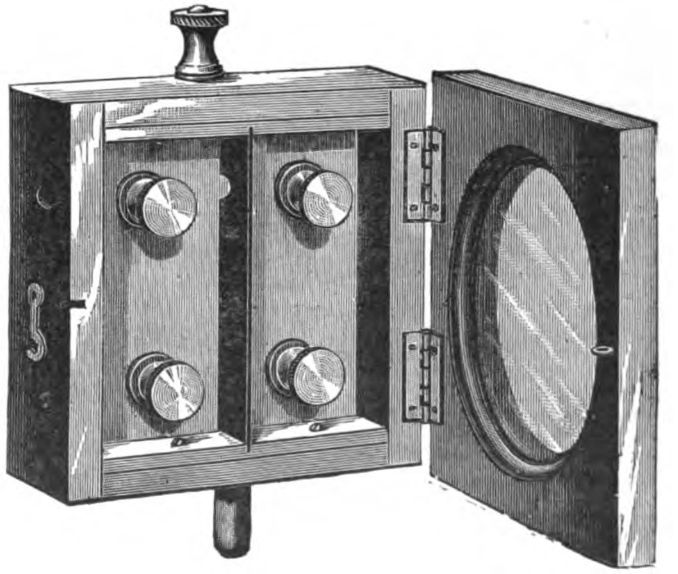
In a handsome blue and white cover, with a cord loop for hanging up at the desk, appears a very useful publication by Chas. A. Schieren & Co., the well-known belt manufacturers, of 47 Ferry street, this city. It contains cuts and descriptions of their electric perforated belts, and of the interesting processes by which it is given its finish and strength. There are also various directions for handling belts, and tables, rules, etc., for calculating horse power, length, etc. After this comes a series of testimonials from electric railways and another from electric light plants, and these are supplemented by a complete cipher code. The whole is very effective and useful.

AMERICAN TECHNICAL PAPERS FOR TURKEY.

Tewfik Bey Eb-uz-zia, Directeur de l'Ecole des Arts et Metiers, in Constantinople, has requested Dr. Cyrus Adler, a commissioner of the World's Columbian Exposition, and an officer of the U. S. National Museum, now in Constantinople, to furnish him with a copy of each of the prominent technical papers published in the United States, and the Museum is now complying with his request. Mr. G. Brown Goode, the assistant secretary of the Museum, has carried out the wish of Tewfik Bey by sending him recent numbers of such papers as would be of use to him, and, it it is hardly necessary to add, has included The Electrical Engineer

THE RUMRILL SAFETY BOX.

The accompanying illustration represents the Rumrill double fusible cut-out box, which is coming into extensive use on electric street cars, as a protection to armatures. The box is six inches square by four deep, and contains two separate plugs, or safety strips, having a capacity of 45 and 65 amperes, respectively. The 45 ampere strip is the one normally used, and, should this blow, the 65 can be switched in, this being the heaviest current that can pass through the motor. The trouble is thus confined to one car, and does not interfere with the rest of the line.



The Rumrill Double Fusible Cut-out.

This device is controlled by Emmet Bros. and Griswold, 150 Broadway.

WESTERN TRADE NOTES.

George B. Foster, formerly of the Thomson-Houston Co., is now with the Illinois Electrical Material Co. as general traveling representative.

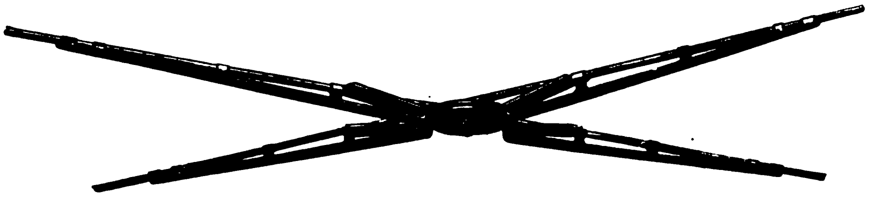
The Riverside Park Railway Co., of Sioux City, Ia., have awarded the contract for all the overhead equipment of their new eight mile road to the Electric Merchandise Company, of Chicago. This contract brought out the sharpest competition from all parts of the country, and the greatest credit is reflected on Mr. A. H. Englund for carrying off the honors in face of such odds.

The Electric Merchandise Co., of Chicago, have a testimonial from the Chattanooga, Tenn., Electric Street Railroad as to their raw hide pinions, which are found "practically noiseless." One set has run 12,000 miles.

THE EMERSON DOUBLE INCLINE ADJUSTABLE CROSSOVER.

Among the novelties lately brought out by the Emerson Electric Manufacturing Co., St. Louis, is a double incline plane crossover, which is illustrated in the accompanying engraving. Four central ribs form the main inclines and four upper plates form auxillary inclines on which the flanges of the trolley wheel travel while passing from the central ribs to the centre plate at the gap. The flanges of the trolley wheel engage with the upper incline plate before passing off the end of the central rib, thus preventing any sudden upward movement of the trolley wheel as as is the case with crossovers as now manufactured.

The inclinations of the upper plate and the central rib are so arranged as to carry any kind of trolley wheels now in use.



The Emerson Double Incline Adjustable Crossover.

Trolley wheels of different systems can pass the crossover with perfect ease. Old trolley wheels wherein the groove is deeply worn can pass as freely as new ones.

The crossover is adjustable to any angle and is applied without cutting or bending the trolley wires and can be reset for any new position such as might be caused by expansion of the trolley wire. The company are also getting out a switch or turnout embodying the double incline plane features.

THOMSON-HOUSTON ELECTRIC RAILWAYS.

The Thomson-Houston Electric Company has just closed a contract for 40 additional cars with the Cincinnati Street Railway Co., of Cincinnati, O., and for 6 cars with the Pueblo City Railway Co., of Pueblo, Col.

During the recent snowstorm in Denver, Col., there was not one cable line in operation, while the Thomson-Houston electric cars were operated without the slightest difficulty. The Denver Tramway Co. has decided to abandon the 18th street cable and use electricity as a means of car propulsion.

The Thomson-Houston Electric Co. has also closed contracts with the Rock Creek Railway, Washington, D. C., for 12 cars; Harrisburg City Passenger Railway, Harrisburg, Pa., for 14 cars; City Electric Railway, Little Rock, Ark., 28 cars; Jefferson Avenue Railway, St. Louis, Mo., for 25 cars; Oxford Lake Line, Anniston, Ala., 6 cars; Allentown & Bethlehem Rapid Transit Co., Allentown, Pa., 15 cars; Marquette City & Presque Isle Co., Marquette, Mich., 3 cars; Braddock & Turtle Creek Railway, Braddock, Pa., 3 cars; Salt Lake Rapid Transit Co., Salt Lake City, Utah, 3 cars; Buffalo Street Railway Co., Buffalo, N. Y., 12 cars; Pittsburgh & Birmingham, 2 cars (making the fourth Thomson-Houston electric railway in Pittsburgh, Pa.); Troy & Albia Street Railway, Troy, N. Y., 20 cars; St. Louis & Suburban Street Railway Co., St. Louis, Mo., 45 cars; Chattanooga and North Side Railway, Chattanooga, Tenn., 4 cars.

CENTRAL ELECTRIC CO.

The Central Electric Company have recently arranged with the Bryant Company to handle their sockets and switches, and already report large sales. They carry a complete stock of all sizes and capacities. The orders for the "Improved Candee" line wire as recently received by the Central Electric Company have taxed to the utmost their facilities for handling a large business, and, in consequence, have tested the factory's capacity to keep them in a large stock of all sizes in anticipation of the spring business. The Central Electric Company are about to place a new carbon battery upon the market, the principal features being the purity of the carbon and the shape of the glass jar, which fits so tightly to the carbon that it makes it virtually air tight and thus prevents the evaporation of the solution.

AN ELECTRICAL PORTRAIT GALLERY.

No one could fail to be interested in, or pleased with, the excellent collection of portraits made by *Modern Light and Heat*, and given in its recent Convention issue. The series embraces 87 pictures, massed together on half a dozen pages of the paper, and the great majority of the portraits are very good, coming out with notable distinctness and fidelity. Mr. Ross is to be congratulated on the success of this electrical "round up," and we beg to acknowledge the courtesy that led him to include in his gallery members of The Electrical Engineer staff.

NEW ENGLAND TRADE NOTES.

The Economic Electric Manufacturing Co. of Boston, have issued a neat little price list of the now well and favorably known "Economic" incandescent lamp. These lamps are made from 10 to 75 candle power and in all colors, mounted in bases to fit the sockets of any standard system, and are of all voltages, from 45 to 120 volts, inclusive. Their prices have been fixed to meet all competition, and are very low, that on 500 lots of 16 candle-power lamps being 80 cents with a discount of 45 per cent. and a rebate of $5.00 per hundred for all returned lamp bases with platinum wires intact. The Economic have made a strong bid for business, and have been very successful so far, having already over 30,000 in use in little more than six months' active business career.

Mr. A. L. Daniels, of the Eureka Tempered Copper Company, of North East, Pa., has been favoring Boston and the East generally with a protracted visit. Tempered copper is now being very extensively used by all manufacturers of electrical apparatus, and Mr. Daniels is exhibiting a very handsome line of samples.

Mr. H. H. Cutler, of Waltham, Mass., well known as a manufacturer of mast arms, lamp hoods and other electric specialties, has decided to go out to Chicago to join Mr. George Cutter, where they will be associated in the manufacture of electrical goods. Mr. Cutler will have full charge of the manufacturing department, his long training adapting him specially for that purpose.

The Thomson-Houston Electric Company.—A standardizing bureau has been formed among the different factories of the Thomson-Houston system. The members are Messrs. Dalzell, of the Schuyler Electric Co., Phipps, of the Brush Co., Talbot, of the Fort Wayne Co., Randall, of the Excelsior Co., H. S. Manning, of the Chicago office of the T.-H. E. Co., Rohrer and Ekstrom, of the Lynn factories, and Lovejoy, of the Boston office. It is standardizing all the various parts in the various factories, meters, cut-outs, switches, switch-boards, lightning arresters, etc.

The Eastern Electrical Supply and Construction Company, of Boston, have imported from France one of the most useful novelties for yachtsmen ever placed on sale in Boston, namely, a musical fog-horn.

By a simple invention the dry battery is made to perform a service which has heretofore been accomplished only by incessant blowing. By the mere pressure of a button a loud and musical blast is evolved, which can be continued at pleasure, giving the man at the wheel complete control of the signals. These horns are made in all sizes, for use on the smallest cat-boat or the largest schooners. By the addition of a series of horns, a blast as loud as a steam whistle can be made; and by putting in circuit a combination switch, a musical scale can be run up and down which is well calculated to "startle the natives."

Mr. H. C. Hawks, lately manager of the New England business of the North American Construction Company, of Pittsburgh, has recently taken over in his own name the whole business of this company in New England, and has bought out their entire stock of tools, apparatus, etc., and will conduct a complete general electric engineering business. He will furnish complete plans, specifications and estimates for central stations and isolated plants, and will carry on a general wiring business. Mr. Hawks has had a long and wide experience in all systems of electric lighting, and has worked in every capacity, so that he brings a thorough practical knowledge of the business to assist him. At a meeting of the Northampton city council last week, the street lighting committee was authorized to close a contract with Mr. Hawks, for lighting the city with about 100 arc lights of 1,200 candle-power capacity. This is to be done for $58.50 a light. Mr. Hawks will continue to make his headquarters, as before, at 620 Atlantic Avenue, Boston.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XI. MARCH 25, 1891. No. 151.

EICKEMEYER'S DIFFERENTIAL MAGNETOMETER.

BY

Chas. Steinmetz.

"IF you know what kind of iron you have." Everybody knows how often the most exact theoretical calculation of electric machinery is made valueless by this condition of doubt. A short time ago I had the pleasure of listening to a very interesting lecture on the theory of compound-winding of dynamos; everything was considered very carefully and put into equations, so that it became possible to lay out compound dynamos with the highest degree of exactness, "if you know what kind of iron you have." It was this very expression that made me feel sad, just as much as it did, I believe, every other electrical engineer who ever met face to face with the disappointing uncertainty brought into electrical engineering by the unknown properties of the most important magnetic conductor, iron.

In Mr. Eickemeyer's well-known electrical factory in Yonkers, there is an instrument of his invention, which enables the determination of the magnetic properties of iron with a high degree of exactness and in so short a time, that a large number of samples of iron can be tested magnetically in a few minutes.

The principle of this instrument resembles somewhat the principle of the well-known differential-galvanometer, applied to the magnetic circuit. In Fig. 2, suppose F_1 and F_2 were two E. M. F.'s, connected in series; for instance, two cells of a battery, x and y the two resistances which we want to compare. Either resistance x and y is shunted, respectively, by a conductor a and b of equal resistance, which influences a galvanometer-needle G in opposite directions but with equal strength.

Then the zero-position of the needle G shows that the electric current c_a flowing in a is equal to the current c_b in b. But, let the current in x be c_x, and in y, c_y; then we must have:

$$c_a + c_y = c_b + c_x;$$

because the currents c_a and c_y are the two branches of the same integral current as c_b and c_x.

Therefore, if $c_a = c_b$, then,

$$c_x = c_y.$$

But, if $c_a = c_b$, and $a = b$, the difference of potential at the ends of a (or, what is the same thing, y), is equal to the difference of potential at the ends of b or x, and therefore, the current in x and y, and the potential differences being the same, it follows that $x = y$.

That is, this method of connection allows us to compare an unknown resistance x with a standard resistance y.

Now, instead of "electric current," say "magnetic current" or "number of lines of magnetic force;" instead of "electromotive force" or "potential difference," say "magnetomotive force;" and, instead of "electric resistance," say "magnetic resistance," and we have the prin-

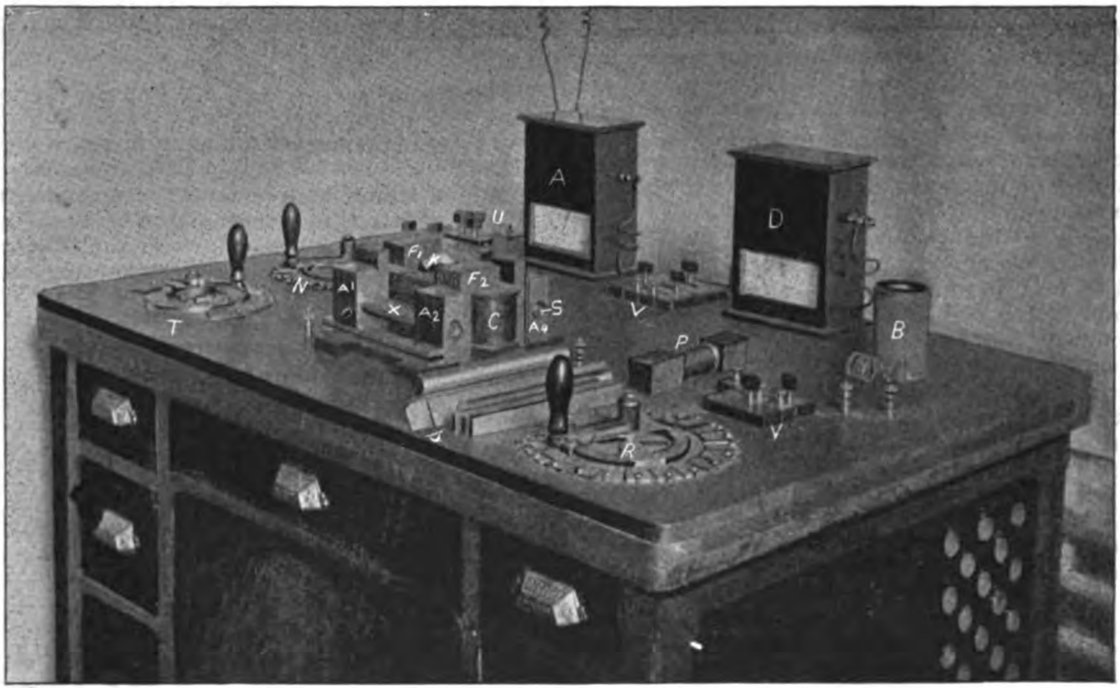


FIG. 1.—EICKEMEYER'S DIFFERENTIAL MAGNETOMETER.

ciple of Eickemeyer's magnetic bridge, or differential magnetometer.

Indeed, for electric measurements, only one electromotive force F would be sufficient. But the air being a magnetic conductor, also, the use of two equal magnetomotive forces in series at two diametrical points of the magnetic circuit is necessary to keep the opposite points of the circuit at the same magnetic potential.

The magnetic circuit of the Eickemeyer differential magnetometer consists of two pieces of best Norway iron, ⊔⊓-shaped, shown in the illustration of the complete instrument, Fig. 1, and in the diagram Fig. 3 at F_1 and F_2. The middle portion is surrounded by a magnetizing coil C. Therefore, if coil C is traversed by an electric current, the front part s_1 of the left iron piece becomes south, and the back-part n_1 north polarity; the front part of the right iron piece n_2 becomes north, and the back part south; and the lines of magnetic force travel in the front from the right to the left, from n_2 to s_1; in the back the opposite way, from the left to the right, or from n_1 to s_2, either through the air, or, when n_2 and s_1, or n_1 and s_2 are connected by a piece of magnetizable metal, through this and through the air.

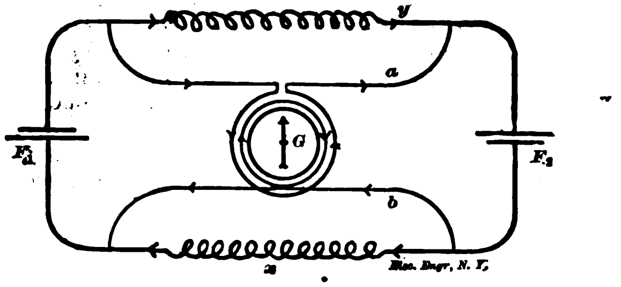

FIG. 2.—EICKEMEYER'S DIFFERENTIAL MAGNETOMETER.

In the middle of the coil C stands a small soft iron needle with an aluminum indicator, which plays over a scale K, and is held in a vertical position by the lines of magnetic force of the coil C itself, deflected to the left by the lines of magnetic force traversing the front part of the instrument from n_2 to s_1, deflected to the right by the lines traversing the back from n_1 to s_2. This needle shows by its zero position, that the magnetic flow through the air in front from n_2 to s_1 has the same strength as the magnetic flow in the back from n_1 to s_2 through the air.

Now we put a piece of soft iron x on the front of the instrument. A large number of lines go through x, less through the air from n_2 to s_1; but all these lines go from n_1 to s_2 through the air at the back part of the magnetometer, the front part and back part of the instrument being connected in series in the magnetic circuit. Therefore the needle is deflected to the right by the magnetic flow in the back of the instrument.

Now, we put another piece of iron, y, on the back part of the instrument, then equilibrium would be restored as soon as the same number of lines of magnetic force go through x, as through y, because then also the same number of lines go through air in the front as in the back. As will be noted, the air here takes the place of the resistances a and b, influencing the galvanometer needle G, as in the diagram, Fig. 2.

The operation of the instrument is exceedingly simple and is as follows: Into the coil C an electric current is sent which is measured by the ammeter A, and regulated by the resistance-switch R. Then the needle which before had no fixed position, points to zero.

Now, we lay the piece of iron, the magnetic properties of which we want to determine, on the back part of the instrument. The needle is deflected to the left. On the front of the instrument we put Norway iron rods of known cross-section and known conductivity, until equilibrium is again restored. Then the iron in the front has the same magnetic resistance as the iron in the back, and the ratio of the cross sections gives directly the ratio of the conductivities; so that by a single reading the magnetic conductivity of any piece of iron can be compared with that of the Norway iron standard.

For absolute determinations, the iron is turned off into pieces of exactly 4 square centimetres cross section and 20 centimetres in length, as shown at X and S, in Fig. 1, both ends fitting into holes in large blocks of Norway iron, A_1, A_2, A_3, A_4, which are laid against the pole pieces S, N, of the magnetometer, so that the transient resistance from pole face to iron is eliminated.

An example may show the operation more clearly: A piece of very good annealed cast steel is laid into the blocks A_1, A_2, in the front of the magnetometer. It has the usual size of 20 centimetres length and 4 square centimetres cross-section. An equal rod of best Norway iron, the standard, S, is put on the back of the instrument. The needle is deflected from zero, but not much; the cast steel is very good. To bring the needle back to zero, we have to add in the front .2 square centimetre of Norway iron.

Therefore, 4 square centimetres of Norway iron have the same magnetic conductivity as 4 square centimetres of this cast steel + .2 square centimetre Norway iron, or:

4 sq. cms. of cast steel = 3.8 sq. cms. Norway iron; that is, the magnetic conductivity of this kind of cast steel is as high as 95 per cent. of that of Norway iron!

We now change the magnetizing current in C, decreasing it from 7.5 to .5 ampere. We now have to add .5 sq. cms. of Norway iron to restore equilibrium. Therefore, for very low magnetization the magnetic conductivity of this cast steel is only $= \frac{35}{40} = 87.5$ per cent. of Norway iron. For high magnetization it increases up to 96 per cent.

To get rid of the remanent magnetism, a reversing switch T allows us to reverse and to break the current in C.

Such a determination is done very quickly, and permits, in half an hour, of testing a large number of samples of iron, delivered from foundries, etc., to choose the iron best suited for the intended use, and not to buy "a pig in a poke."

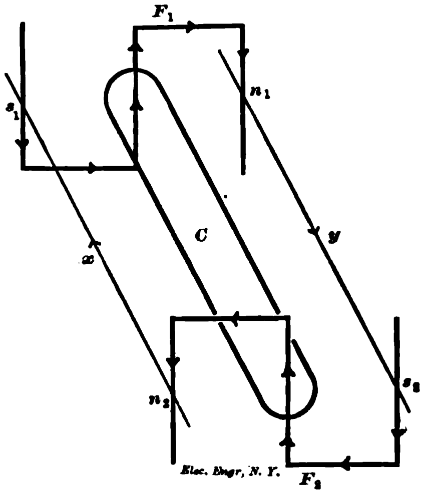

FIG. 3.—EICKEMEYER'S DIFFERENTIAL MAGNETOMETER.

To determine the intensity of magnetization in the iron, that is, the number of lines of magnetic force, the coil B, of a known number of turns, is slipped over the standard magnetic resistance S, and the current in C, that is the magnetism, reversed. The reversal of magnetism induces an electromotive force in the coil B, which is measured by the throw of the galvanometer-needle in D, and gives the exact number of lines of magnetic force in the standard.

This magnetometer is us Mr. Eickemeyer's factory with the greatest success for the determination of the field magnet iron in the dynamo machinery in the following way: On the very iron frame of the dynamo or motor, which constitutes its magnetic field, is cast a square piece of iron 8 inches long and 1¼ inch square. This is broken off, turned off in the middle for a length of 4 inches and to 1⅛ inch diameter, and placed on one side. Such a piece is shown in Fig. 1, at P.

This piece of iron is compared in the magnetometer with the Norway iron standard, and thus gives for each machine the magnetic properties, not only in general, of the kind of iron used, but of the very casting which constitutes the dynamo field. By means of this the field winding is determined; more can hardly be expected.

I need not remark, that by testing a very large number of different sorts of cast iron and steel, many interesting results are found; for instance, that for cast iron with very low magnetization the conductivity is often as low as 30 to 40 per cent. of Norway iron, but increases with increasing magnetization up to 80 per cent. and more. Some kinds of annealed steel are even better than ordinary wrought iron; one sample attained for average magnetization, (7.5 amperes) 97½ per cent. of Norway iron.

The indicator needle, in the middle of the coil C, is closely surrounded by a small coil E. This, when excited in the opposite direction to the main coil C, decreases its directing force and thereby increases the sensitiveness of the instrument, which is very useful for high magnetization where the directing force of C is very great. This "astatic coil," when kept excited in the same direction as the main coil C, after the current in C is broken, affords the means for determining remanent and permanent magnetism by the coil B. This coil B is slipped over the standard resistance S, at the other side of the bridge, being the sample of iron to be tested for its hysteresis. Then, after breaking the main current in C, the needle is directed only by the coil E, which has no influence upon the magnetic circuit of the magnetometer, and therefore the needle is deflected by the remanent magnetism. Now the needle is brought back to zero by a current in coil B, and this current, measured by ammeter D and regulated by the resistance switch N, gives the magnetomotive force of remanent, or, when a permanent magnet is used, of permanent magnetism. At *s* are shown pieces of Norway iron of known cross section, used as fractional standard resistances.

One Norway iron standard, exactly like S is cut into two pieces, well fitted to each other, which, when withdrawn, leave a gap between them, for testing sheets of different materials or even liquids brought into the gap or air spaces.

For instance, if an air gap of $\frac{1}{32}$ inch is left between the two pieces of Norway iron, then the magnetic conductivity for very low magnetization is decreased by this air gap to only about 20 per cent. of the unbroken standard S, but increases for increasing magnetization, until, for very high magnetization, this air gap has almost no influence upon the magnetic circuit. This, from the known saturation curve of the Norway iron standard, allows of determining the magnetization (the number of lines of magnetic force) by means of the behavior of air gaps, without always going back to the use of the ballistic galvanometer. And thus a large number of applications of this instrument for magnetic tests have been made; still more can be devised, into which I cannot enter more deeply here, having sufficiently shown its usefulness, I believe.

The lower part of the desk, upon which the instrument is mounted, contains accommodation for a storage battery for giving the exciting current. Terminals U allow a current to be sent in from outside, as is often more convenient in an electric factory. Switches and cut-outs V regulate and control the different circuits, and the back part contains the resistances, so that the instrument, with the desk upon which it is mounted, is entirely self-contained.

THE ENTZ ELECTRIC RAILWAY SYSTEM.

THE novel electric railway system shown in the accompanying illustrations was devised by Mr. Justus B. Entz, of this city, and consists in the employment of a continuous stationary armature, which extends from end to end of the track. The armature exercises its force upon a field magnet, which is carried by the car with the aid of brushes that also travel at the same rate as the car, and that convey the current from mains, which are laid along the route, to that portion of the armature which is under the influence of the field-magnet.

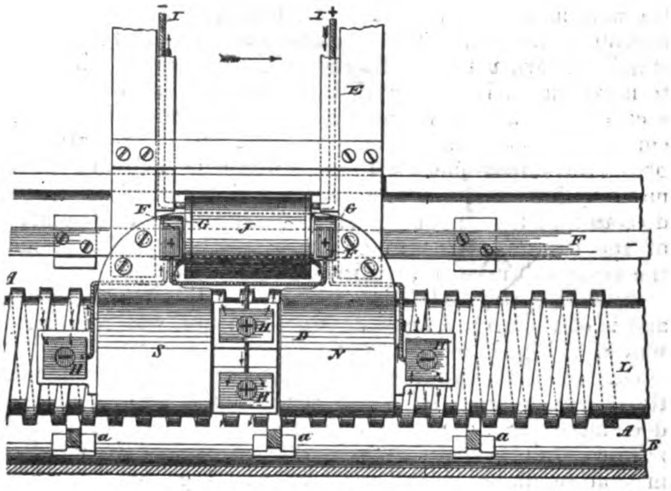

FIG. 1.—THE ENTZ ELECTRIC RAILWAY SYSTEM.

As will be seen, the armature A is a continuous coil occupying the entire length of the conduit. The field magnet D is suspended within the conduit from the car and embraces the armature as shown in Fig. 2. The mains E F are secured within the conduit, and extend from end to end of the road. The contact pieces G G are carried by the magnet D, and bear against the mains, while the brushes H H are carried by the field magnet, and bear upon the outside of the coiled armature.

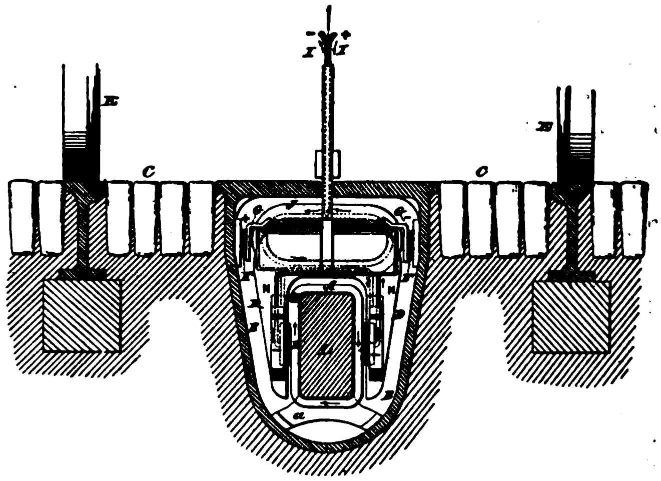

FIG. 2.—THE ENTZ ELECTRIC RAILWAY SYSTEM.

The magnet D is excited by the aid of the conductors I I that lead from the car to and around the spool J of the magnet. The winding of the armature A is that of a continuous coil upon an iron core, and corresponds to a Gramme ring armature cut at one place and laid out straight. The field-magnet has a single coil on its spool, and its pole-pieces from either end extend down and embrace the top and sides of the armature. The poles are of opposite polarity, as indicated by the letters N S, it being necessary that the current should flow in opposite directions in that portion of the armature which is inclosed by each set of pole-pieces. To this end the brushes are placed and connected as shown, a brush of one sign, say +, being between two poles and between two brushes of the opposite sign, say—, of which there is one at each end of the magnet. With the brushes connected in this way the current will enter at the middle + brush, divide and flow in opposite directions under the opposite poles to the outside brushes.

The effect of the current flowing in the armature upon the field-magnet is to cause the one which is capable of moving to move in relation to the other, and as in this instance the armature winding is fixed the magnet will tend to move and will carry with it the vehicle to which it is secured, and as the current in the armature coil is kept continually beneath the magnet by means of the traveling brushes, the movement will be continuous, and this movement will be in either direction at will, according to the direction of the current in the winding, and the polarity of the magnet. Changing either and keeping the other the same will reverse the direction of motion.

An iron core L is placed within the tubular armature, and is of the same length as the armature, which is represented in Fig. 2, in cross section.

One of the advantages claimed for this system is that the power applied is in the nature of a direct pull, and does not depend upon the weight of the car for its traction power. Another advantage is that the armature winding may be regulated to suit the traffic as regards speed and power along different parts of the same route. Thus, on a grade, the windings may be closer together than on the level, giving a greater average efficiency. It is also evident that all conductors carrying dangerous currents can be completely sealed in conduits which admit of no mechanical or electrical communication with the street or car, which may be propelled in either direction upon the same track, and the speed regulated at will.

THE INFANCY OF ELECTRICITY.

BY

Edwin J. Houston

It may interest the readers of The Electrical Engineer to know that the book referred to by Prof. Sweet in his interesting communication, entitled the "Infancy of Electricity,"[1] is not a cyclopedia of the sciences, as suggested, but is the last paragraph of the introduction to a work entitled "A Complete Treatise on Electricity in Theory and Practice, with Original Experiments," by Tiberius Cavallo, F.R.S.

Cavallo's book is in three volumes of between 300 and 400 pages each, and is, probably, the most complete work issued on early electrical science. The copy in my possession is the fourth edition and was published in London, in 1795. The third volume was added since the publication of the third edition. It is probable, therefore, that the date assigned for the first appearance of the statement of Prof. Sweet, viz., in 1785 or 1789, is correct.

Cavallo, in speaking of the discovery of the Leyden phial in 1745, says: "Then, and not till then, the study of electricity became general, surprised every beholder, and invited to the houses of electricians a greater number of spectators than ever before assembled together to observe any philosophical experiment whatsoever."

Then follows the matter quoted by Prof. Sweet: "Since the time of this discovery," etc.

I have been using the quotation referred to as an illustration in my lectures for some years past, and have now given the exact title of the work, believing it may be of general interest.

SAFETY AND AESTHETICISM IN CONVERTER INSTALLATIONS.

BY

G. T. Evans.

It seems scarcely more than yesterday that this subject would have been abortive and absurd. But to-day, when the converter has spread over the country and is multiplying at a rate that an English sparrow might well envy, a few words in relation to the matter may not be inopportune. Though there are sharp breezes in the scientific air of "light without heat," and manufactured fire-flies may appear at any moment, it is probable that the converter will occupy the field for some length of time.

It is therefore assumed that its installation should be made in the most substantial manner, and not, as is often the case, as if it were to have a mere butterfly existence. In this connection the placing of converters on poles is to be avoided. Poles do not last forever, and their life is not augmented by being top loaded with heavy converters. But if poles are used for the purpose the converters should be hung on the cross arm by flat iron hooks. Bolts or lag screws not only weaken the cross arm but their employment makes the installation and any future change or removal more than doubly difficult.

The usual way of fastening converters to walls of buildings is also open to objections. Simply securing by screws to wooden walls or plugs driven into masonry is doubtless safe enough for a time, if the screws have a solid hold; but I would not care to spend a score of years under converters thus put up; and it is likely that my life insurance agent would object as strenuously to this arrangement as his brother of the fire department does to the unsoldered joint. A converter hung securely from a medium large galvanized iron bolt, passing nearly or entirely through the wall, is practically safe for almost any time. It also possesses the advantage of being easily exchanged when necessary. Insulators can be applied as customary, the screws for these merely entering the wall to hold the converter from swinging.

From a purely aesthetic point of view the converter is by no means a beautiful object, and it is not to be wondered that people object to have these "stoves" and "coffee mills" stuck conspicuously on their property. Very often it is impossible to place a converter except on the front wall of a man's building. If such a disposal is unavoidable, the constructing engineer should make the best of the situation and not add to the scene by a superfluous number of wooden brackets and unnecessarily large wire. Iron brackets should be used at all times when unsightliness is to be avoided. But, where possible, the converter should be hidden or put out of sight as far as it can be.

Locating them around corners or behind bay windows and wings has a pleasing effect of absence. But when at all feasible, put the converter within the building. Here, if properly placed, it will give the least trouble, be easy of access (converter fuses *do* give out sometimes) and be not so dangerous as a box of matches. The hypercritical fire underwriter will become educated to this truth sometime and will no more require a converter to be hung on the outside of a building than he now does a cook stove or a tallow candle.

Crawfordsville, Ind.—A temporary injunction has been issued forbidding the city of Crawfordsville from purchasing an electric light plant. H. S. Braden applied for the injunction as a citizen and taxpayer, but it is generally understood that he represents other parties. The reasons assigned by the petitioner are that the city has no right to do commercial lighting, and that the resolution passed by the council to buy a plant is invalid because the Mayor cast the deciding vote.

STORAGE TRACTION ON THE LEHIGH AVENUE RAILROAD AT PHILADELPHIA.

The recent withdrawal of the storage battery cars from the Lehigh Avenue Railroad in Philadelphia, has given rise to numerous inquiries as to the causes which have led up to this event. This being the case, a brief statement of the conditions involved and of the results actually obtained will be of great interest at the present moment, when the demand for storage traction is more emphatic and evident than ever. In the first place, only four cars were in regular commission on the road. It is evident, therefore, that the fixed charges alone were so great that a dozen cars might have been operated with the same, or very little increase in, expense. Again, the road was so situated that the traffic which existed was but very light and even then subject to very great fluctuations between winter and summer months. To this we must add the fact that the road presented a succession of grades and curves which were a tax of the most serious nature upon the storage batteries.

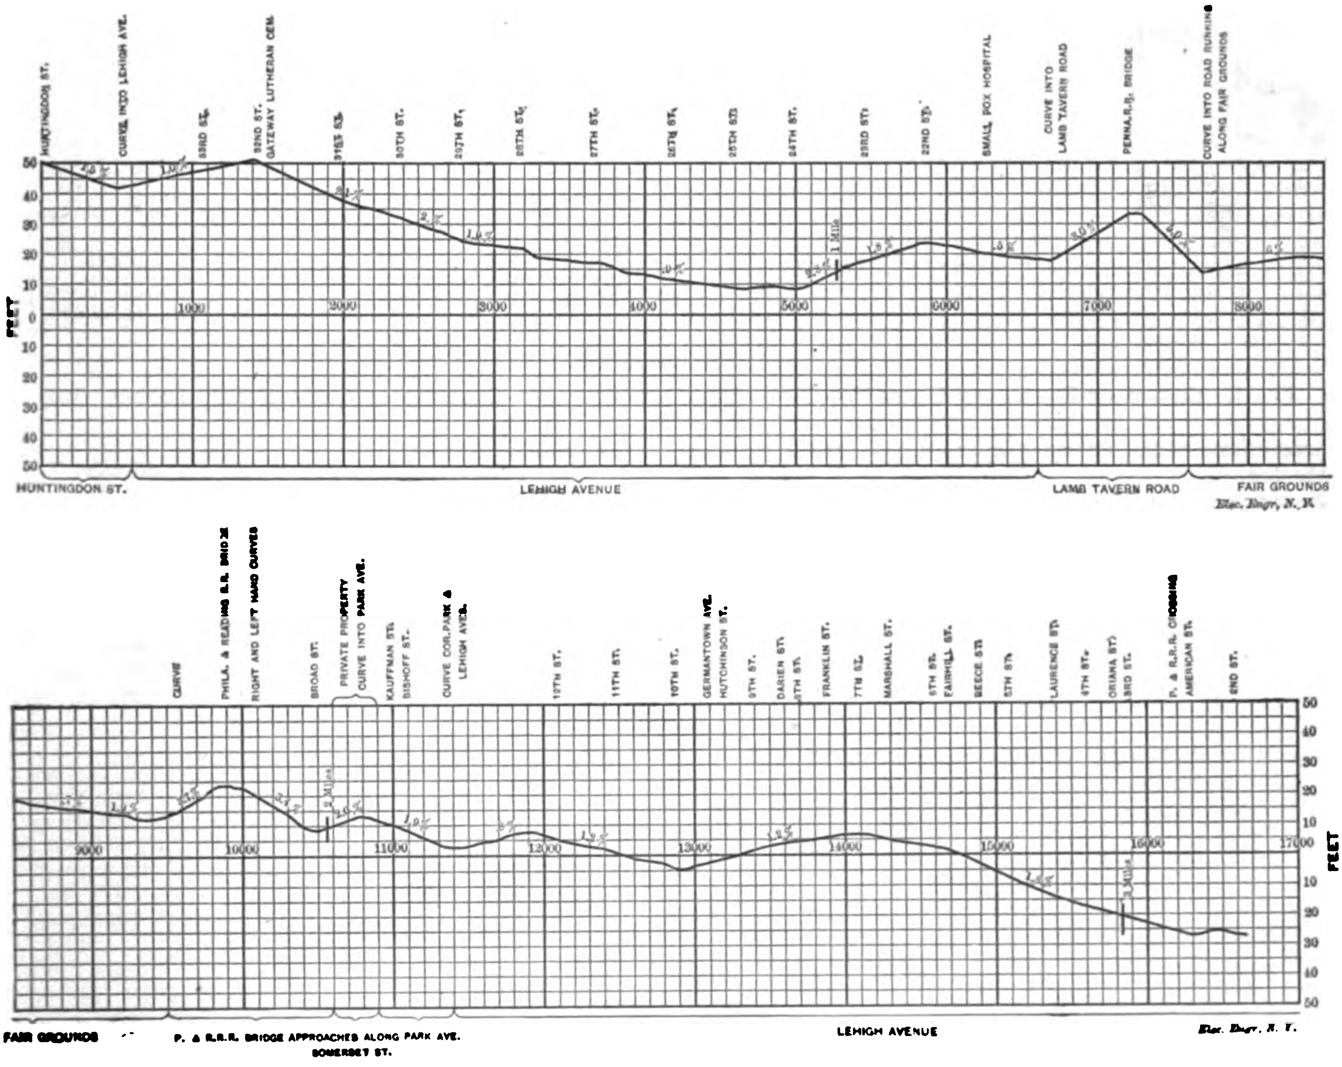

FIG. 1.—PROFILE OF LEHIGH AVENUE RAILROAD, PHILADELPHIA, PA.

It has given opportunity of making observations upon this class of traffic, which are of the highest importance and which go to prove that with proper conditions storage battery traction can be successfully undertaken by street railways. A glance at the profile of the road, shown in Fig. 1, will give at once an idea of its character. In a length of 3.15 miles it embraces a large number of curves, and grades reaching as high as 5 per cent.; there being, in fact, scarcely a level spot on it, and the terminal of the road being 75 feet below the starting point in level. The cars employed weighed 4,500 pounds, empty, and with the batteries 15,000 pounds; this without passengers. With the passengers, therefore, the total weight was between 9 and 10 tons. Only two sets of batteries per car were employed, and with three cars on the road the round trip was made in 57 minutes, covering a distance of 6⅛ miles; while with four cars, 60 minutes were allowed per round trip. The road was operated electrically between May 1 and January 16, covering a total running time of 37.28 weeks; the total number of miles run was 52,271 and the number of passengers carried, 336,454; and in order to give an idea of the fluctuation of traffic mentioned above, we give below the number of passengers carried in July and August, 1890:

	Total.	Daily Average Exc. Sundays.	Sunday Average.
July,	58,650	1,736	3,818
August,	59,890	1,514	4,104

From this, it will be seen that the daily average of passengers over the road amounted in August to only 1,514, while the Sunday averages reached 4,104, and upon these days the average load was between 12 and 15 tons, and subsequent months show even a much larger falling off in traffic than those given above. This was due to the fact that the road was principally patronized by people traveling to Fairmount Park, and naturally the approach of winter caused a large diminution in this traffic.

As we have stated above, the road has given excellent opportunities for observation and as a proof of this we need only compare the results obtained and the improvements made as the work progressed. Thus, in Fig. 2, is given a chart showing the records made on Sunday, Aug. 31, 1890, which was one of the heaviest traffic days on the road. Here, it will be seen, the electrical energy in horse power, taken from the batteries, which are represented by curves in full lines, fluctuated enormously, as did, of course, the amperes drawn from the cells. The fluctuation in voltage of the cells shown in the upper curve is also characteristic of the heavy duty to which the cells were subjected.

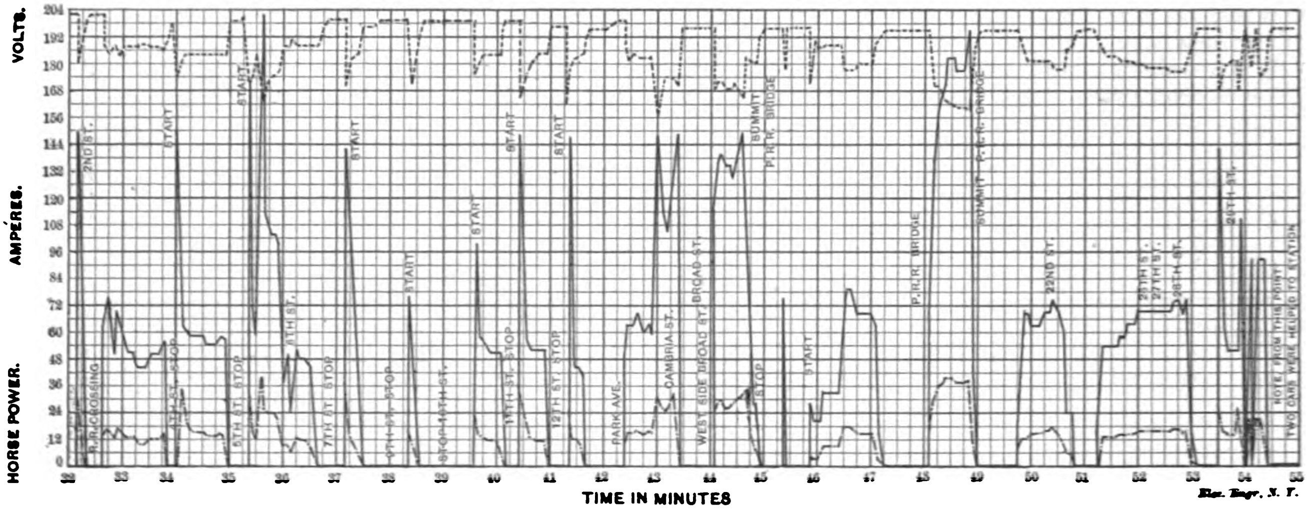

FIG. 2.—CURVES OF ELECTRICAL HORSE POWER, CURRENT AND VOLTAGE.—OBSERVED ON STORAGE CAR, AUGUST, 1890.

As many as ten trips per day, were run, representing 63 miles; on some occasions with one charge of the hundred cells of battery employed.

With the improvements which were made as the result of observation, the character of the work was materially improved. This is admirably shown by the chart, Fig. 3, which gives the result of a similar set of observations made on Oct. 15, 1890. This was also made with a fully loaded car, and, as will be seen, the fluctuations in the current are not nearly so violent, and, as a result, the energy drawn from the battery shows a large diminution, indicating the efficacy of the improvements introduced. These improvements consisted, in the first place, in the motors and in the batteries. Each car was equipped with two motors, and the experience gained has shown almost conclusively that a higher general average efficiency can be obtained by commutating the motor than by commutating the batteries, in order to obtain the varying powers required for operation.

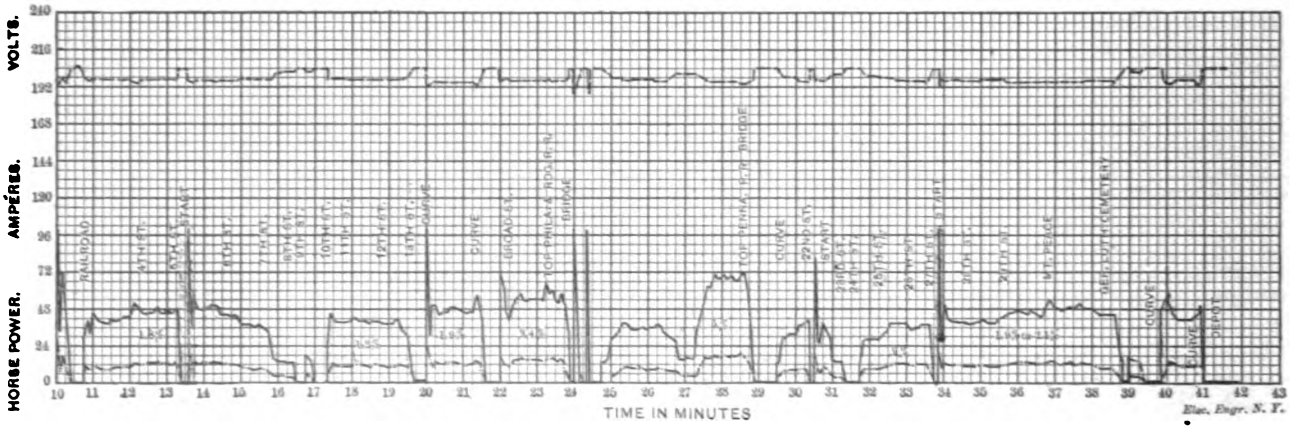

FIG. 3.—CURVES OF ELECTRICAL HORSE POWER, CURRENT AND VOLTAGE.—OBSERVED ON STORAGE CAR, OCTOBER, 1890.

The results obtained and graphically indicated in chart, Fig. 3, are given in the following table:

Distance	3.15	mile
Time per trip	31	minutes
" of discharge	26½	"
Weight carried	8.5	tons
Discharge Rate:	100	amperes
Maximum	70	
Mean	40	"
Mean per ton	4.7	"
E. M. F.:		
Maximum	205	volts
Minimum	192-188	"
Mean	196	"
Ampere Hours:		
Total	17.9	
Mean per mile	5.69	
" " " per ton	0.67	
Horse Power:		
Maximum	18.4	
Mean	10.48	
" per ton	1.15	
Horse Power Hours:		
Total	4.65	
Mean per mile	1.47	
" " " per ton	0.17	

Further experiments made show that the results even here obtained could be improved upon, and subsequent experiments showed that the mean horse power per miles with a heavy load over this road did not exceed 1.25, while with a light load it formerly amounted to 1.3.

Worm and worm wheel gears were employed on these cars to connect the armature shaft with the car axle.

This method of gearing has, in the past, been criticised, as involving a large loss through friction, but the results obtained on this road have shown conclusively that, when properly designed, this method of gearing is not only highly efficient, but possesses other unquestioned advantages. As illustrative of the high efficiency of this form of gear we give in Fig. 4, the results obtained in a series of tests of a worm and worm wheel made by the Electric Car Company of America. The ratio of the worm to worm wheel was 1 to 8. With this arrangement the curves show that the efficiency above 300 revolutions ranges between 80 and 90%. This fact, it will be remembered, bears out the statements made by Mr. Anthony Reckenzaun, in a paper read by him before the American Institute of Electrical Engineers, in September, 1887, and which led him to prefer this form of gearing to all the others which he discussed at the time. The storage batteries with which the experiments on the Lehigh Avenue road were made, were those of the Electric Storage Battery Company.

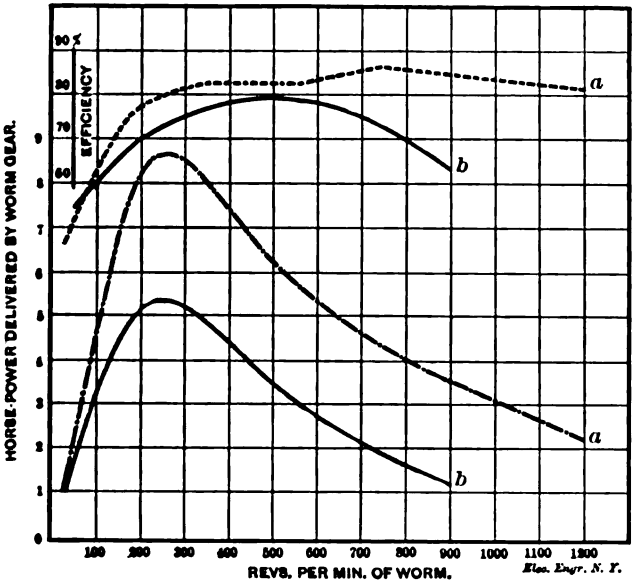

FIG. 4.—CURVES SHOWING TEST OF WORM GEAR.

For some more recent tests of the worm gear used on the Lehigh Avenue Railroad at speeds equivalent to between 5 and 10 miles an hour of the car, the mean efficiency was 82 per cent. with a mean of 12 mechanical horse-power on the axle. The maximum efficiency was 85 per cent. at 550 revolutions of the armatures (equal to about 5½ miles an hour of the car), giving 15 mechanical horse-power on the axle, the ratio of revolutions of armature to axle being 8 to 1.

Although financial reasons dictated the withdrawal of the electric cars from the road, the admirable records kept, of every detail of operation, show that the outlook, far from being discouraging, is of the most hopeful character, and that it is only a question of operating storage cars under suitable conditions, to make this method a commercially successful one.

ELECTROLYSIS IN WATER SOFTENING.

For softening water by means of hydrated oxide of lead cheaply, it is necessary to obtain the oxide, and the following method has been devised by M. Villon. A solution of sodium nitrate is placed in a vat divided into two compartments by a diaphragm; lead electrodes of large surface are placed in the solution and the current from a dynamo then passed through. The sodium nitrate is decomposed, caustic soda being formed in the negative compartment and nitric acid at the positive pole, from which it dissolves a certain quantity of lead, forming lead nitrate. When the current has passed through the liquid for a certain time, the solutions are run from the two compartments into a second vat and there mixed by means of an agitator. The soda precipitates hydrated oxide of lead and itself forms sodium nitrate; the solution is then filtered and the nitrate solution again submitted to electrolysis.

AN ANALOGY BETWEEN THE MAGNETIC AND VORTEX RING FIELD.

BY

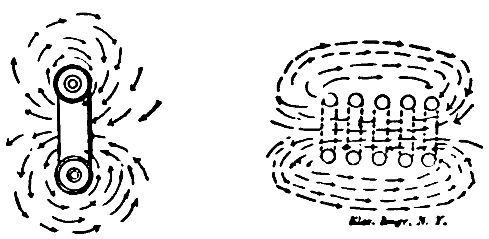
A. E. Dolbear

In the editorial in THE ELECTRICAL ENGINEER for March concerning my paper on "Change of Form Affecting a Magnetic Field," the remark is made that "the assumption of the ring form for a magnetic molecule makes it difficult to reconcile this theory with the observed phenomena of magnetic polarity;" and this leads me to the attempt to point out a curiously close analogy, if nothing more, between the magnetic *field* and the vortex ring *field*, if one may employ such an expression.

Imagine a simple vortex ring, and consider the direction of the rotations that constitute it a ring. All the motions are inward on one side and outward on the other. Looked at in cross section in a plane parallel to the axis of the ring it appears as in Fig. 1, these outgoing and incoming lines being exactly like the pictured lines of force of a magnet.

The effect of the rotary motion upon the circular axis extends to quite a distance beyond the boundary of the material that is actually rotating, as may be shown by making such rings in any convenient way and noting their behavior when they are in proximity to each other or to other objects. For instance, a swift moving vortex ring four or five inches in diameter, if started *parallel* to a surface, as of a table, will be sure to move towards the table and break upon it even at the distance of six inches or more, following a path as an ordinary ball does when thrown horizontally. Also, two such rings, if moving towards each other in the same straight line, will have their movements visibly retarded before they collide, acting, therefore, as if they mutually repelled each other. This shows that they have a *field*, or a space outside of their actual body, in which their motions induce some sort of a stress.

As the actual rotations are inward on one side, and outward on the other, it follows that *the properties of the two sides of the ring are unlike.*



FIGS. 1 AND 2.

Now, imagine that two, or more, such rings were arranged upon the same axis as in Fig. 2, so that all their similar faces are turned one way; then would this external field be represented by precisely the same set of lines that are pictured about a straight bar magnet. Its opposite ends would possess different proportions, mutually repelling similar ends and attracting dissimilar ends, as do magnets. Now, when one recalls the fact that what knowledge we have of magnetism goes to prove that magnetism must be a property of some molecules, if not of all, and that it is generally agreed among physicists, that what is called polarity in a body is simply the combined effect of having all the molecules facing one way, so as to make the *fields* of the individual molecules simply additive, it will be seen how close the phenomena of vortex rings come to the phenomena of magnetism.

I do not mean to assert anything as to their identity, but only to point out a simple and easily understood mechanical analogy between them.

If, to go one step further, one could imagine a current of electricity to be circulating around this ring circuit, he would at once have the exact condition for a magnet, and a magnetic field. This, indeed, was the idea in Ampère's theory of the magnet, but applying it to the vortex ring gives to it a degree of definiteness it did not possess before, and what we have been sadly lacking in, in dealing with the questions of electricity and magnetism, is machanical conceptions of atoms and molecules that would lend themselves in any degree to such phenomena.

SILICON BRONZE WIRE FOR ELECTRIC RAILWAY CONSTRUCTION.

BY

Frank J. Stone

In building an electric railroad, the engineer will naturally endeavor to make his overhead construction as light, strong and symmetrical as possible, both for the sake of appearance and durability. In selecting a trolley wire, therefore, he must look for strength, durability, conductivity, non-corrosion and ductility, combined in the highest degree, and if one of these properties is in the least deficient, it must be reinforced in some way. Silicon bronze wire stands at the head of the list of metals in strength, durability, non-corrodibility and ductility, and is only slightly deficient in conductivity, out-ranking every other metal or alloy used in electrical construction except copper. How shall we make up for this single deficiency?

One of the most eminent electrical engineers in this country quickly overcame the difficulty by using copper feed wires for carrying the current, and making the silicon bronze wire a contact or trolley wire only. In this way the extra resistance of the silicon bronze would occasion absolutely no loss of current, and as the electrical capacity of the trolley wire is sufficient to carry the current for all cars that would ever be between two in-feeds, there is no danger of overheating.

This feeder system then solves the problem in a most satisfactory manner. By the use of feeders we not only entirely overcome the sole objection to the use of silicon bronze, but at the same time provide for an absolute maintenance of electrical pressure the full length of the line, no matter how the cars may happen to be distributed. If, by accident, the trolley wire should be broken, the cars located beyond the break will receive their current through the feeder wire, just the same as if there had been no accident to the trolley wire.

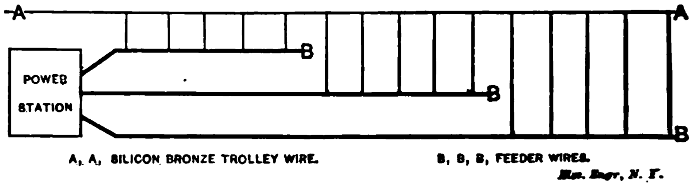
We can summarize the advantages of silicon bronze wire as follows: First, a tensile strength of 80,000 lbs. per square inch, which is nearly twice that of large diameters of hard drawn copper wire. Second, a ductility of 30 to 35 twists in 6 inches on a No. 4 B. W. G. wire. This far exceeds the standard of any other metal of equal strength and diameter. Third, great resistance to wear, as a 6½ mile road operated since construction equivalent to 800,000 car miles, shows no appreciable wear on straight away track. Fourth, absolute resistance to corrosion, which insures a perfect contact, even where the wire is used in mines and under other similar trying conditions. Fifth, freedom from breakage by surface abrasion, a frequent source of trouble with hard drawn copper wire.

As against these excellent qualities may be placed the seeming disadvantages of its higher resistance than copper; this is, however, entirely overcome by the system of feeders before mentioned.

Silicon bronze wire has a conductivity equal to about one-half that of hard drawn copper wire, so that in estimating the quantity of wire required for an electric road, it is only necessary to consider the trolley wire as being one-half its actual size; in other words, according to the best accepted methods of construction, where a No. 4 B. W. G. silicon bronze trolley wire is used, it should be calculated as having the capacity of a No. 8 B. W. G. copper wire, and the feeder wires must be given sufficient sectional area to carry the electrical energy required, less this amount.

The accompanying diagram shows not only the method by which the lack of high conductivity is perfectly compensated for, but also shows how the potential is maintained throughout the whole length of the line, even to portions of the road remote from the power station. As the feeders are not tapped before reaching the point where the power is to be used, and can be thoroughly insulated over their entire length, we can count upon charging the trolley or contact wire at any point with its full potential, namely, 500 volts.

In the matter of appearance, the silicon bronze wire is of great advantage in the construction of electric roads, for we are able to use a small wire on account of its high tensile strength. Practice shows that a wire .238 inch in diameter and weighing but 905 lbs. per mile has sufficient strength and conductivity. This wire has the capacity of supporting almost two tons actual weight, and on account of its small diameter and strength can be drawn much more taut than copper wire. This fact alone gives the line a well proportioned appearance, doing away entirely with "clothes line sag" so noticeable when hard drawn wire is used.



Silicon Bronze Trolley Wire with Feeders.

The entire overhead construction is also lighter, as we have to support a wire weighing only 905 lbs. per mile instead of one weighing often over three times as much.

The feed wires carrying the current are placed on the poles at the sides of the street, where their weight can be easily supported, and where they are practically out of sight. Especially is this the case when the road runs through the resident portions of a city and among trees. In many localities the feeders can be carried up side streets and alleys, thus making a large saving in the lengths of the conductors and removing all superfluous overhead construction from the principal streets on which the road is built.

As the extra resistance of the silicon bronze trolley wire is entirely overcome by the use of feeders, and, therefore, does not occasion the slightest increase in the consumption of coal at the station, all possible objection to its general use is completely removed, and on account of its many superior qualities, it has already been adopted by a large number of our leading electrical engineers.

TELEGRAPHERS MUST LEAVE THE ORDER.

By order of General Manager Clark, of the Union Pacific, all telegraph operators of that line in Colorado have been notified that they must sever their connection with the Order of Railway Telegraphers or leave the service of the company at once.

THE EVANS SYSTEM OF DRIVING DYNAMOS.

BY

Henry T. Conant

One of the many mechanical problems which present themselves to an electrical engineer in designing an electric plant, relates to the transmission of power to the dynamo. In many instances, owing to size or shape of available space, this is a very perplexing question and may be considered of enough importance to warrant a short discussion of the principles involved in two of the more common methods now in use.

The transmission of power by ordinary belting has been made the subject of so much experimental study by eminent engineers, that we are fortunately in possession of a great deal of reliable data, from which can be established standards for comparison under various conditions which may be imposed.

From the published results of a large number and variety of such tests, and the well-known principles upon which they are based, it has been pretty definitely determined under what conditions a belt must be used to give the best (most economical) results, and what, under these conditions, are the tensions in each side of the belt—the power that it can carry without undue slip or strain—the pressure exerted on the bearings, and the coefficient of friction necessary to maintain these conditions.

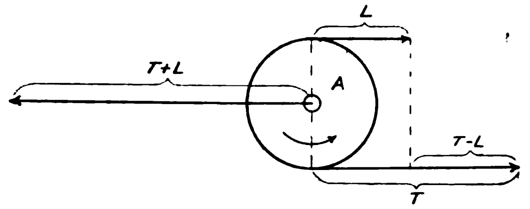


FIG. 1.

Rope transmission, link belting, and other similar methods, all depend on the same principles, and are subject to the same laws as ordinary belting, and, although their efficiences may not be the same, the type to which they belong is a distinct one, and may be fairly represented by good double oak tanned leather belting.

Direct coupling, as a method of transmission, is certainly most efficient, but as a method of driving dynamos of comparatively small capacity is, for many reasons, undesirable. Inasmuch as the questions involved in its use are chiefly those of reconciling the speeds of engine and dynamo in an economical and satisfactory manner, and not of efficiency in transmission, it does not properly have a place in this discussion.

The action of forces when power is transmitted by belts is shown in the diagram, Fig. 1, in which T represents the pull of the tight side of the belt, and L the tension in the loose side, when work is being done. It is evident that while the sum $(T + L)$ of these two forces exerts a pressure on the bearings of pulley A, only their difference or $T - L$ is available to do work, for it requires a portion of the force T, equal to L, to neutralize the tension in the loose side of the belt.

The conditions under which the Evans system operates are shown diagrammatically in Fig. 2. The line P represents the pressure on the bearings, and the line F, the tangential force which is active in doing work and which, it is obvious, corresponds with $T - L$. Moreover, the force P corresponds with $T + L$, and the fraction $\frac{F}{P}$ with the similar fraction $\frac{T - L}{T + L}$.

In order, therefore, that the two methods may be equally efficient as regards the pressure on the bearings, the values of those two fractions must be equal.

The maximum value of $\frac{F}{P}$ is determined by the greatest coefficient of friction between iron and leather, obtainable under the peculiar conditions found only in the Evans system.

In many of the large number of belt tests which have been made, the pressure on the bearings, due to the pull of the belt, was actually weighed, thus giving direct readings for values of $T + L$.

Corresponding values of $T - L$ were found by dividing the number of foot lbs. measured by a brake, transmitted per minute, by the speed of the belt in feet per minute. From values of $T + L$ and $T - L$ obtained in this manner, values of T and L are readily found by simple addition and subtraction. The relations of the forces T and L so found, vary between wide limits under different conditions; but from inspection of the tabulated results of a long series of such tests, it appears that the relations which they should bear to each other to give the most economical results, in any given case, are quite clearly defined. Without going into a more detailed discussion, it may be said that with pulleys of equal size, to obtain the best results, $\frac{T}{L}$ should be not far from 2.35. The coefficient of friction corresponding to this value may be deduced from the formula $\frac{T}{L} = e^{f\theta}$, in which e is the Naperian logarithm base, and θ the arc of contact on the smaller pulley.

The value of f found in this way when $\frac{T}{L} = 2.35$ and $\theta = 180°$, is 0.27. This coefficient is one from which the best of results would be predicted in the light of independent tests made to determine the coefficient of friction of leather belting on iron pulleys, under conditions as nearly as possible like those met with in practice.

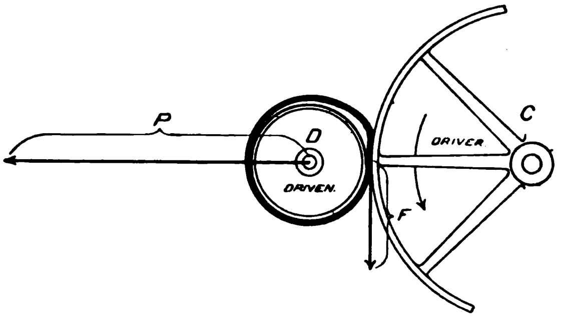

FIG. 2.

In dynomo work, the contact of the belt on the smaller pulley frequently does not exceed 150°. In such cases the value of the fraction $\frac{T}{L}$, corresponding to $f = 0.27$, becomes 2.03.

Values of $\frac{T - L}{T + L}$ derived from values of $\frac{T}{L} = 2.35$, and $\frac{T}{L} = 2.03$, are $\frac{T - L}{T + L} = 0.40$, and $\frac{T - L}{T + L} = 0.34$, for the pulleys of equal diameters, and for those of unequal size, respectively.

If, then, the coefficient of friction between iron and leather, as used in the Evans system, is as great as 0.40 and the assumptions made in regard to the open belting are correct; as much power can be transmitted with no more pressure on the bearings than with ordinary belting, working under the most favorable conditions, with pulleys of equal size; and the same would hold true in comparison with the unequal-sized pulleys similarly used, if the coefficient of friction should be 0.34.

Just how great this coefficient may be, and to what extent it is, influenced by the peculiarities of the Evans system could be easily determined by experiments similar to those made to determine constants for open belting.

Values of $\frac{T-L}{T+L}$ as low as 0.20 and as high as 0.78 have been recorded. In order to obtain the smaller value, however, it was necessary to employ a very great pressure (85 pounds with a belt speed of 4,500 feet) per horse-power; or, in other words, this value was obtained by using an unnecessarily large belt, which was strained unnecessarily tight. The value of f in this case was 0.13.

On the other hand, to obtain the 0.78 value, a value of f as great as 0.66 was required, although the pressure on the bearings per horse-power with a belt speed of 4,500 feet was only 10 pounds. An excessive amount of slip, however, was required to maintain these conditions; a slip so great, in fact, that it was with difficulty that the belt could be kept on the pulleys. In other words, the belt had either to be so much overworked, or else run so slack, that there was an impracticable amount of slip. The values selected for $\frac{T-L}{T+L}$ (0.40 and 0.34) as of the best to use, correspond to a coefficent of friction of 0.27, a slip of about 6 feet per minute, and a pressure on the bearings of about 18 and 21 pounds per horse power for the equal and unequal sized pulleys respectively.

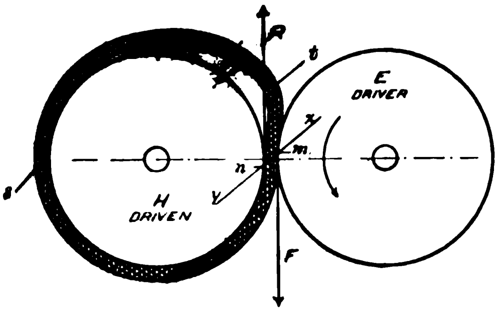

Fig. 3.

These comparisons do not have to do with the width of belt necessary to do equal amounts of work in each case. This might be determined in the case of the open belt, by dividing the tension in the tight side of the belt by the greatest allowable strain per unit width, and in the other case by dividing the total tangential force required to transmit the given power, by the greatest tangential force per unit width which can be safely employed.

The width of belt required in the latter case will be greater than in the former, but it does not follow from this that the pressure in the bearings must be greater. Within the safe working limits of the friction, the pressure on the bearings is probably independent of the width of belts used.

The peculiarities of the Evans system, to which reference has been made, are manifested by the shape into which the friction belts are distorted, as shown in Fig. 3. In order that there may be uniform motion the driving force, F must of course be balanced by a nearly equal force R, and while the force F is applied on the outer side of the belts, the resisting force R is exerted on the inner side, thus forming a couple, of which the thickness of the belt is the moment arm. The rotative effect of this couple distorts the belts into the shape shown, and the loose part of the belt will not be found in practice at s as might be expected, but at t, if the conditions are as shown in the diagram.

In consequence of this *trip*, the centre of pressure of the driving pulley E on the belt, will be transferred to a point m, above the line of centres (in the case shown) and to a point n below the line of centres on the driven pulley H, and the pressure will be transmitted through the belt in an oblique direction $x\,y$. Owing to this feature, moreover, the area of contact on both pulleys is of course increased, and the contact surfaces distributed in a decidedly advantageous way. It is probable, too, that a higher coefficient of friction is obtained on account of the more perfect contact arising from the comparatively great pressure per square inch, than would be obtained if the belt were used in the ordinary way.

Another interesting fact in this connection is that, since the pressure is partly due to the effect of the couple, and since the moment of the couple is proportional to the load, the pressure on the bearings is also to a certain extent proportional to the load. This is very prettily demonstrated in practice in that it has been found that a pressure on the belts so slight that they could be slipped between the pulleys when at rest, is sufficient, when supplemented by the "trip" of the belts, to carry the full load. In ordinary belting, the sum of the tension in each side of the belt ($T+L$) is known to be nearly constant, whether at work or at rest.

Comparative results so far obtained in practice, agree well with the theoretical comparisons which have been made. It has been found that under perfect conditions a tangential force of 28 or 30 pounds per inch of width can be sustained by the friction belts without overloading, and without undue pressure, but, as perfect conditions are rarely obtainable, that 20 or 22 pounds is the safest and best constant to use.

It is of course essential to the successful working of this friction, to have pulleys which are both firm and true, and to have their faces parallel *when under pressure.*

It would ordinarily be impracticable to employ a very wide face on an overhung dynamo pulley on account of the difficulty which would be found in keeping the outer edge up to its work, and for this reason it would be desirable to use an outboard bearing, or a "double drive" on dynamos consuming more than forty or fifty horse power. By such special arrangements much larger powers can be handled to good advantage; the objection to them, if it is an objection, being the necessity of having a special armature shaft, and, in the case of the double drive, of the commutator not being quite so accessible from all sides. The mechanical advantages which would be gained, however, would in most cases outweigh the objections.

THE ELECTRIC LIGHTING OF TRAINS.

Professor Kohlrausch has reported on the experiments which have been made in the electric lighting of railway trains between Cannstadt and Stuttgart, and his conclusions are that such lighting must be independent of the locomotive, and that it must be on the accumulator system. He disapproves of carrying a dynamo, owing to the consequent increase in the number of couplings in the train, and advocates charging the accumulators by means of fixed engines at various stations, and changing the batteries when approaching exhaustion. This system is stated to have been successfully carried on by the Oerlikon Company on Swiss railways.

A USEFUL APPLICATION OF THE CHLOROCHROMIC ACID BATTERY.

An interesting application of the chlorochromic acid ($CrCl_2O_2$) battery to portable incandescent lamp lighting was made last autumn in France by the underground explorers, MM. A. Martel and G. Gaupillat, who employed a battery of the Renard type (zinc platinized-silver) containing six cells, and capable of supplying current during five hours to a 12 or 15 candle-power lamp. Candles and magnesium lights were out of the question, owing to the exhalations from the stagnant subterranean waters. The whole apparatus was 12in. high, 8½in. in diameter, and weighed 17½lbs., which was not excessive for the purpose, since the lamp was carried on a small boat. The composition of the solution was approximately as follows: Chromic acid, 1½lb.; hydrochloric acid, 1 pint; sulphuric acid, ½ pint; water, 3 pints.

A SIMPLE ELECTRICAL SAW.

In a recent issue of the *Chemical News*, Mr. H. N. Warren says, whenever a powerful electrical circuit is closed by a platinum wire of suitable dimensions, the well-known heating effect of the same is at once manifested; yet no one seems to have been struck with the idea that the simple heated wire may be employed as a most effective disintegrator of the hardest organic compounds. A similar but more convenient article may be constructed as follows:—It consists of two upright pieces of very stout brass or copper wire, connected at the lower extremities by a nonconducting medium, while across the top is secured a piece of moderately thin platinum wire. On thus connecting the apparatus by means of side binding screws to the terminals of about four Bunsen batteries, the platinum wire at once becomes heated to bright redness, and will be found to cleave the hardest wood with great facility, insomuch that a large number of useful appliances may be thus manufactured in a short space of time. Owing, however, to the platinum wire frequently breaking, probably on account of its intimate contact with the carbon whilst at an elevated temperature, the author has devised and used with advantage a modified wire, formed by depositing metallic platinum upon fine steel wire, by exposing that substance to the action of the electric current in contact with an ethereal solution of platinic chloride.

DO THE LINES OF FORCE ROTATE WITH THE MAGNET?

Although many eminent men of science have vexed themselves over the question whether the lines of force caused by a magnet do, or do not, rotate with it as it revolves, no one, as far as we are aware, has suggested a crucial experiment capable of deciding the matter. This task has been attempted by Mr. Tolver Preston, who, in the February number of the *Philosophical Magazine*, proposes to rotate a cylindrical magnet near a metal disc placed perpendicular to the axis of revolution. If the lines rotate with the magnet the disc will become charged to a higher potential at the edges than at the centre, owing to its behavior as a disc dynamo. If, however, the field remains fixed while the magnet revolves, the poles will become charged to a higher potential than the middle portion, owing to the tendency to induce currents through the magnet itself. This polar charge will act by ordinary static induction on the disc, the two faces of which will exhibit electricities of opposite kind. Tests made with a delicate electrometer of the electrical state of the disc should therefore decide between the two hypotheses. Unfortunately the experiment can only be made by those who have very delicate apparatus at command, as it appears that otherwise very high velocities of revolution are necessary to produce the effects predicted.

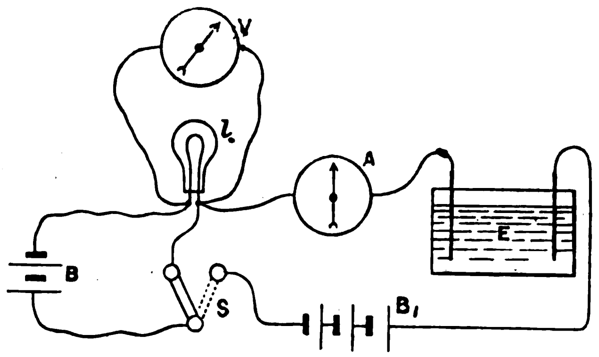
INSULATING HORSES.[1]

A writer describing a terrible storm at the Cape of Good Hope which came upon the cavalry known as the "Diamond Field Horse," killing ten men and five horses, advises that cavalry men and their horses in tropical countries be insulated,—in other words, that the bits and accoutrements be covered with rubber, that the swords of the men have rubber scabbards, that their sword guards be covered with hard rubber, and that all of the metallic portions of their accoutrements that are more for ornament than for use, be rubber trimmed. Aside from this, we would add that a rubber bit is one of the most comfortable things ever put in a horse's mouth, and if he were shod with rubber shoes—as many of them are—his feet would last very much better, he would be able to travel more miles a day, and while it might not keep him from the lightning stroke, it would certainly add to his comfort and efficiency.

TESTING PRIMARY BATTERIES.[2]

BY I. PROBERT.

Having several times had occasion to make tests of new forms of small primary batteries which were especially designed to work direct small incandescent lamps, I found it impossible to determine the exact amount of current flowing by the direct use of an ammeter, as the resistance of the latter, although low, was still sufficiently great to materially reduce the current when the ammeter was inserted in the circuit. The arrangement shown in the figure, I found, got over the difficulty entirely, and, as it may prove equally interesting to others, I am induced to publish it.



Method of Testing Primary Batteries.

The battery B, to be tested, is joined up to the lamp, l (which has a voltmeter, V, across its terminals), the switch, S, being turned to the position shown. Under these conditions the battery works direct on to the lamp which glows at its full brilliancy, and the voltmeter, V, gives the voltage between the lamp terminals. In order to determine the current, the switch, S, is turned to the position shown by the dotted lines; this brings into circuit the auxiliary battery (I have used, preferably, small portable accumulators for this purpose, as they have a low resistance), the ammeter, A, and the electrolytic cell, E. The current from B, although reduced by the resistance of the ammeter, is reinforced by the auxiliary battery, B^1, and by adjusting the distance between the plates of the electrolytic cell the current can be adjusted to the greatest nicety, until the deflection on V is the same as it was previous to the turning of the switch, S; hence the ammeter, A, now shows the current which under the latter conditions was flowing through B. The observation being taken on A, the switch, S, is turned back to the position shown in the figure, and the battery, B, continues to work under the practical conditions.

It should be added that by this arrangement not only can the true energy expended in the lamp be obtained for the stated candle-power, but by removing the lamp from the battery, and adapting it to a movable bridge astride a mercury trough, the light can be easily measured without interposing unnecessary resistance between the battery and its lamp.

CONSUMPTION OF RAW MATERIAL.

During the past year the Thomson-Houston Co. consumed nearly 2,500,000 pounds of copper wire, and about 450,000 pounds of brass rods, castings, etc.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, MARCH 25, 1891. No. 151.

> *We bring our doubts and differences to the bar of nature, and the verdict is convincing to all. It is truth, which is the soul of science.*—*Alfred M. Mayer.*

ELECTRIC TRAIN LIGHTING.

THE number of railroad cars in this country which have thus far been equipped with the electric light exceeds greatly that of any other country, but up to the present time very few, if any, statistics have been published which would enable the engineer to determine the exact economy of this mode of illumination as compared with others, heretofore in vogue. We have been told, in a general way, that the electric method of illumination is much more expensive than that by gas or oil, but the exact ratio has been left to conjecture, and has probably led to erroneous conclusions among those engaged in the departments in which this work falls. Considerable interest therefore attaches to a paper on Car Lighting, recently read before the Western Railway Club at Chicago, by Mr. George Gibbs, mechanical engineer of the Chicago, Milwaukee & St. Paul Railway. This gentleman, whom we know to be a thoroughly competent engineer, has gone very exhaustively into this subject and the results obtained by him are well worthy of study. In his paper he classifies the methods of lighting under eight headings, namely: 1, candles; 2, vegetable oils; 3, mineral or petroleum oils; 4, ordinary coal gas; 5, carburetted coal gas; 6, rich or oil gas; 7, carburetted air; 8, electric. It is the last, of course, which interests us particularly, and in treating of this Mr. Gibbs at once dismisses primary batteries from consideration, as being, on the face, too expensive for practical application for this purpose. Regarding secondary batteries employed alone, this method is also claimed by Mr. Gibbs to have shown itself incapable of extended application, although it is now said to be in use on the Canadian Pacific to a limited extent, on the Burlington, Cedar Rapids & Northern, and on some parlor cars on the Pennsylvania Railroad. The lighting of trains by a dynamo driven from the car axle is also pointed out to be attended with mechanical difficulties on account of the nature of the bogie trucks employed in this country.

Mr. Gibbs began experiments on the St. Paul road about two years ago and first employed an arrangement involving a dynamo and storage batteries. His experience went to prove that this method was too expensive, its most serious defect being the large first cost, rapid depreciation of batteries and multiplicity of details requiring skilled attention, as well as the poor economy of the special engine and the wasteful character of the whole arrangement in current. After one year's experience with this arrangement Mr. Gibbs came to the conclusion that greater economy could be obtained by relying upon direct generation of the current by a dynamo run by a special steam engine, and this is the plan which has been in operation ever since, and upon which his calculations are based.

Probably most interest attaches to Mr. Gibbs' calculation of the cost of the various systems of lighting, and this is shown in the accompanying table:

	Candle power per car.	Running cost per car per hour, cents.	Cost per c. p. per hour, cents.	Cost of equipment per c. p., cents.
Mineral Oil.....	168	2.51	.015	0.67
Pintsch Gas....	170	2.60	.015	3.24
Frost Gas......	180	4.60	.026	2.98
Electricity......	160	9.83	.061	2.47

Here, it will be noted, the cost of equipment per candle power by electricity is less than that of gas by either system enumerated, although considerably higher, as might be expected, than by mineral oil. On the other hand, it is shown that the running cost per car per hour by electricity exceeds that of oil and gas. While the results obtained by Mr. Gibbs may be true as far as they go, we think that a more extended experience with the electric system and the equipment of a larger number of cars will tend to reduce the discrepancy in cost which is now shown to exist. The item for attendance, with electricity, is absurdly large in the figures given. Of the many hundred cars on the road only 64 have thus far been equipped with the electric service, aggregating only 1,128 lamps, so that the basis of comparison is made on but a very small "retail" equipment as compared with the other "wholesale" methods of illumination. As regards the electric system generally, Mr. Gibbs considers it adapted in the present state of the art to special service only. He acknowledges that it fills, in a perfect manner, the requirements for a railroad light, and that in many instances it will undoubtedly pay for itself many times over, and that its cost is at present its only draw-back.

It may not be out of place here to note the fact that Mr. Gibbs points out that many of the requirements of a satisfactory car light system appear to be embodied in the present oil system, or might be, with some improvements which are readily obtainable. Of course this is also to be taken as coming from the "railroad standpoint," but we doubt whether the traveling public will coincide with Mr. Gibbs' views on this point, and are strongly inclined to the opinion that railroad companies will, in spite of the increased cost of electric lighting, find it to their advantage to employ it, as Mr. Gibbs suggests. On the other hand, we believe that tests made on other roads show decidedly greater economy than obtained by Mr. Gibbs and we may soon have occasion to recur to this subject.

STORAGE BATTERY TRACTION.

There are perhaps few practical applications of electric power about which there is a greater lack of knowledge than the true state of storage battery traction, and the conditions which must be fulfilled in order to obtain success. It may be stated broadly that, with the storage battery as we find it even to-day, success can be attained where the conditions do not subject the battery to such heavy duty as to cause its early disintegration, and where the number of cars operated is sufficiently large to keep the fixed charges per car within a proper limit. The recent stoppage of the Lehigh Avenue road in Philadelphia, which had been in operation for nearly a year, has again raised the question of the adaptability of storage batteries to this class of work. But we believe that, taken in connection with the character of this road, which involves heavy grades and curves, the small number of cars in operation, and, above all, the very light and intermittent traffic, the results obtained were no more than could have been expected. The electrical figures show the steady improvement that was going on all the time, and in fact it may be said that it was only a question of time when, even in this instance, results would have turned out more favorably than they did. This remark refers more particularly to the financial question, which, it is true, was the determining factor in the withdrawal of the electric cars. From the operating standpoint, the results obtained were of the most encouraging character, and they also substantiate well the claims made for the worm-gearing employed on these cars. With the advent of a storage battery which will permit the heaviest draughts upon it without deterioration, the storage battery will, we are sure, find a field not only on roads of easy grades, but for those, even, with considerable gradients.

DETERMINING THE QUALITY OF IRON.

Much has been said and written on the law of the electromagnet and its application to the construction of dynamo electric machinery. But, however valuable this data may be from the standpoint of a working theory, all such calculations are based on the assumption that the iron employed has a given permeability or magnetic conductivity. If all irons, even of the same class, possessed uniform qualities, the results of calculations might be applied directly, and give results varying but little from those indicated by calculation. Unfortunately, however, the quality of iron is subject to such large variations that the results obtained in actual practice frequently depart very largely from those of calculation; and when the results, obtained without a proper test of the iron, come out within a reasonable percentage of the pre-determined quantity, it is probably due to a lucky combination of circumstances, in which one error balances another. But with the present state of our knowledge there is no reason why the designer of dynamo electric machinery shall go astray for want of a proper method of determining beforehand the quality of the iron with which he is dealing. It has recently been suggested that much might be gained by the issuance of standard pieces of iron, much in the same way as standards of electric resistances are now issued. While such standard iron bars would, without doubt, be of considerable value, a simple instrument which enables one to determine exactly and expeditiously the magnetic quality of a sample of iron must be still more far-reaching and ought to find a place in every establishment in which dynamo electric machinery is built. The differential magnetometer of Mr. Rudolph Eickemeyer, which is so clearly described by Mr. Steinmetz on another page, will be recognized at once as an instrument which, if intelligently applied, removes instantly the one great factor of uncertainty in the design of dynamo electric machines. By casting a test bar with each field magnet and subjecting it to magnetic tests on the magnetometer, a complete knowledge of each individual piece of magnetic material involved in the construction of machines is obtained. The results already obtained with this apparatus by Mr. Eickemeyer leave no doubt that when once its benefits are thoroughly appreciated the magnetometer will form a prominent adjunct to every electrical laboratory.

TELEPHONIC DISTURBANCES.

Telephony plays such an important part in our daily life that investigations into the nature of the disturbances which are experienced in this work are of the highest importance. The great bugbear of telephony, induction, ascribed, and naturally so, to electro-dynamic interaction between parallel conductors, seemed to indicate that freedom from telephonic disturbance could be obtained by the employment of metallic conductors. More recent researches, however, have shown that other causes must be taken into consideration in the attempt to secure silence in telephonic conductors. Among those who have given this question their consideration, Mr. J. J. Carty deserves special mention on account of the light which he has thrown upon the relatively greater effect which electro-static induction has upon neighboring telephone conductors as compared with that due to dynamic induction. Mr. Carty's paper, read before the Institute, will be found full of suggestions in this field, and the results appear certainly to justify his closing remark that the time may come when we shall return to single telephone circuits in preference to "metallic."

A Trolley Road for New York City.

After a careful hearing of all the statements and evidence on the subject, the New York State Railway Commission has flatly decided in favor of the trolley system for the "Huckleberry" road in the northern suburbs of the city; thus agreeing with the opinion already expressed by the Board of Electrical Control. The Commission says that the electric road will of great benefit to the district through which it passes.

INDUCTIVE DISTURBANCES IN TELEPHONE CIRCUITS.[1]

BY J. J. CARTY.

It was not known until 1838 that the earth might be used instead of a return wire in the circuit of a telegraph line. This fact was discovered by Steinheil, while making experiments to determine whether the track of a railroad could be used to complete the circuit instead of a return wire. Steinheil's discovery has been considered as one of the most important in the art of telegraphy, and since his time it has been the almost universal practice to use the earth as a return in telegraph circuits. When, however, the earth return is used with the telephone, it is found that owing to the extreme sensitiveness of that instrument, many foreign currents, which would produce but little effect on telegraph instruments, become a source of serious trouble. For this reason, in telephony it is often necessary to use a complete metallic circuit. Thus it has come to pass that a return to the original practice of employing metallic circuits, as in the case of the crudest telegraph instruments, is now regarded as a most important improvement in connection with that most highly developed of telegraph instruments, the telephone.

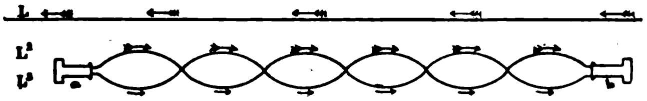

FIG. 1.

To obtain complete freedom from inductive disturbances in the telephone, it is necessary not only to use a metallic circuit, but to place the two wires composing the circuit in a special relation to the source of disturbance. One of the methods of so arranging the wires is shown in Fig. 1.

In this case the two sides of the circuit L^2 and L^3 are twisted spirally about each other, so that their average distance from the disturbing wire L^1 shall be the same. With such a plan, the telephones *a* and *b* are not affected by induction from the wire L^1. This fact has usually been explained by assuming that a current, commencing to flow in L^1, tends to induce two currents in the opposite direction to itself, one in the wire L^2 and the other in the wire L^3; that both currents are of the same strength because the average distance of L^2 and L^3 from the disturbing wire L^1 is the same; and that the telephones *a* and *b* are silent because they are acted upon by two equal and opposite forces. The above theory seems at first sight to be correct, and indicates the line of explanation adopted in many works treating of the subject.[2]

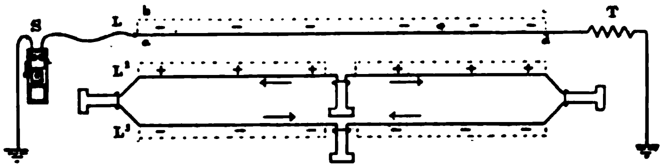

FIG. 2.

I have made a number of experiments which seem to prove that in the case described, the inductive action, instead of tending to produce a simple current in each side of the metallic circuit, actually does produce a number of different currents in each wire and in both directions.

In Fig. 2, L^2 and L^3 are two well insulated copper wires, 500 feet long and three feet apart. These wires are joined together at each end through an ordinary telephone. L^1 is a well insulated wire similar to the other two and placed within one-half an inch of L^2. At one end of L^1 is placed a Blake transmitter T and at the other end is placed a subscriber's bell S; L^1 being grounded at both ends as shown. When the transmitter T is operated, either by speaking into it or by vibrating a powerful tuning fork in front of it, disturbances are produced at the end telephones.

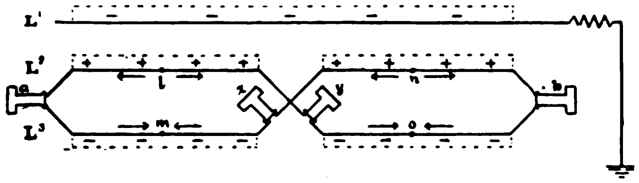

FIG. 3.

If telephones are inserted at the centre of L^2 and L^3 it is found that at those points no sound is heard, while the noise of the end telephones continues as before. This constitutes a simple case of inductive disturbance, and can only be explained by assuming that the wire L^1 acts electrostatically upon the circuit composed of L^2 and L^3, or in other words, that we are dealing with a system of condensers in series, of which L^1 constitutes one plate, the earth another and the wires L^2 and L^3, two intermediate plates which are joined together through the end telephones.

Let us assume that at a given instant, the height of potential along the wire L^1 is represented by the lines *a b* and *c d*, and the charge upon L^1 by the rectangle *a b c d*. The presence of this charge, which we will say is of the minus sign, is accompanied by an equal but plus charge on L^2. This produces a minus charge on the wire L^3, which in turn acts upon the earth. Now we will assume that the potential on L^1 is reduced to zero. This causes a restoration of the equilibrium in the circuit composed of L^2 and L^3, which is accompanied by a set of currents as represented by the arrows. The plus charge on L^2, flowing through the end telephones, neutralizes the minus charge on L^3, thus leaving a neutral point at the centre of each of the wires L^2 and L^3.

In this and the succeeding experiments the induced charges are represented by rectangles. This is not a strictly accurate method, but as an error in this respect only affects the result quantitatively, and cannot alter the conclusions, I have adopted it on account of the simplicity of treatment which its permits.

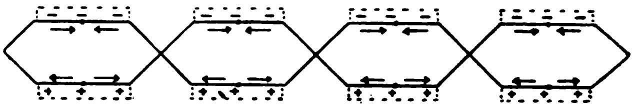

FIG. 4.

The potential along the wire L^1 at a given instant is represented as being constant, as it is found that owing to the high impedance in the instrument S, there is practically no fall of potential in the wire itself. Furthermore, it was found in the experiments about to be described that the results were the same whether the disturbing wire was open or connected to earth through the bell S. There would be a fall of potential along the wire L^1 if it were of such a length as often found in practice, and the distribution of the charge would be modified accordingly. But as this fact would only affect the location of the neutral points, the question of the fall of potential will not be taken into consideration, and the disturbing wire will be shown open at one end.

Fig. 3 shows the same circuits as used in the previous experiment, except that the wires L^2 and L^3 are caused to change places at their centres but are continued in the same plane, as in Fig. 2. This is what is called a "transposition." The telephones at the ends and in the middle are retained as before. Under these conditions, when the transmitter is operated, a diminished sound is heard at *a* and *b*; and *x* and *y*, instead of being silent as in the first case, now emit a sound of the same intensity as *a* and *b*. When telephones are placed at the quarters *l, m, n, o,* the sounds at *a b* and *x y* continue as before, but nothing is heard at *l, m, n, o*. The effect of this one transposition has been to reduce the disturbance at the end telephones *a* and *b*, and to cause a shifting of the neutral points from the centres to the quarters, and an increase of their number from two to four.

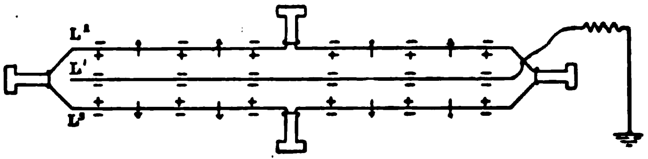

FIG. 5.

An examination of the induced charge shows how these results have been brought about. It will be seen by reference to Fig. 3, that there is on the first half of L^2 a positive charge, and on the second half a negative charge, and on the first half of L^3 a negative charge, and on the second half, a positive charge. When the positive charge on L^2 discharges, half of it goes through the telephone *a*, and half through the telephone *y*. The positive charge on L^3 escapes in a similar manner, half going through telephone *x*, and half through telephone *b*. This produces four currents, two starting from point *l* and two starting from the point *n*. One of the currents from *l* meets a current at *o*, coming from the point *n*, and one of the currents starting at the point *n* meets a current at *m*, which started from *l*. The currents flowing through the end telephones in this case are not so strong as when no transposition is employed, because they are due to an induced charge which is represented by an area half as great. It is found that as the number of transpositions is increased the number of neutral points is also increased, and that the area representing the charge, which escapes through the end telephones is reduced. To obtain silence, therefore, it is necessary to increase the frequency of transpositions until the discharge through the end telephones is so small as not to produce sounds therein. Fig. 4 shows a circuit containing three transpositions, one at the centre and one half way between the centre and each end. In this case, if we could neglect the resistance of the telephones, the current going through the ends would be reduced to one fourth of its original proportions, and eight neutral points would be produced, one in each wire at the centre of each transposition.

---

[1] A paper read before the American Institute of Electrical Engineers, New York, March 17th, 1891.

[2] *A Handbook of Practical Telegraphy*, R. S. Culley, 1885, p. 330. *The Telephone*, Preece & Maier, 1889, p. 134. *Die Technik des Fernsprechwesens*, Dr. V. Wietlisbach, 1886, p. 135.

In practice the impedance of the telephones must be taken into consideration, so that if in Fig. 8, the middle telephones *x* and *y* were omitted, the neutral points would be found to move towards the ends, and the currents flowing through the end telephones would be correspondingly reduced.

According to this theory of transpositions, if the instruments and distances between wires on a given circuit remain constant, for a given period of alternations in the disturbing wire, the number of transpositions necessary to obtain silence will depend on the E. M. F. of the disturbing wire, and the specific inductive capacity of the dielectric. An increase in the value of either of these factors will, if silence is to be maintained, require additional transpositions, their number depending upon the value of the change which is made.

Where the disturbing wire is placed at an equal distance from both sides of a metallic circuit, no noise is produced in telephones located in that circuit, and a balance once being obtained, it is independent of both the E. M. F. of the disturbing wire and the specific inductive capacity of the dielectric. Fig. 5 shows such an arrangement of circuits—L^2 and L^3 are the two wires composing the metallic circuit placed the same distance apart as before, and the disturbing wire is at an equal distance from both. When the disturbing wire is in operation, no sound is heard at the end telephones, or at telephones located at the centres. This may be accounted for by assuming that at a given instant a negative charge is on the disturbing wire, which produces a positive charge on the inside of L^2 and L^3 and a negative charge on the outside of those wires; and that when the charge is removed from the disturbing wire, a set of currents is set up in the wires L^2 and L^3 in a direction at right angles to their axes, as shown by the arrows. In this case the flow is lateral, and no current passes through the end telephones or through telephones located at the centres. It will thus be seen that this method of arranging wires differs essentially in its action from the plan of using transpositions. Unfortunately, however, its practical application is limited to two circuits.

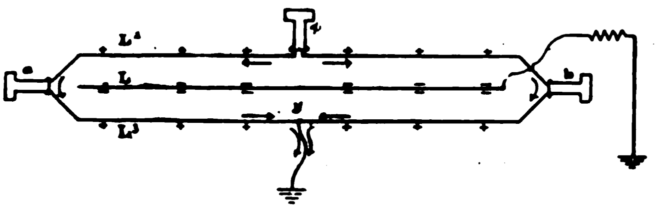

FIG. 6.

Where the disturbing wire occupies the position shown in Fig. 5, the flow in the conductors is lateral only when the wires L^2 and L^3 are insulated from the earth. If a ground be attached to the centre of L^3, as shown in Fig. 6, the flow of current becomes longitudinal, and the telephones *a* and *b* are found to be affected by loud disturbances, while the telephone *x*, at the centre of L^2, is found to be silent. This is because the disturbing wire, which we will say is negatively charged, induces a positive charge upon L^2 and L^3 and a negative charge upon the earth. The discharge in this case is effected by two currents starting from *x*, which thus becomes a neutral point, and passing through the end telephones to the ground as shown by the arrows. If the ground be removed from the point *y* toward the telephone *a*, the neutral point will be found to move toward telephone *b*, and if the ground be put at the centre of resistance of the telephone *a*, the neutral point will be found to be at the centre of the telephone *b*. This is well illustrated in Fig. 7, where *a* and *b* are telephones of special construction, admitting of the attachment of grounding keys K^1 and K^2 at their respective centres. In this instance, when the disturbing wire is in operation and both keys open, no sound is heard at any of the telephones, the flow of current being lateral. If the key K^1 be closed, sound is immediately heard at telephones *x* and *y* located at the centres of L^2 and L^3, but the telephones *a* and *b* are still silent. This is because the charge and discharge take place along the conductors L^2 and L^3 to and from the earth at K^1, thus passing through *x* and *y*, *a* being silent because the currents go through it differentially, and *b* is silent because it is located at a neutral point. To prove that current flows through telephone *a*, another telephone may be inserted in the ground branch at K^1, and it will be found to be loudly affected. If both keys K^1 and K^2 are closed, silence is again obtained in the four telephones *a*, *b*, *x*, *y*. In this case the charge and discharge from the wires L^2 and L^3 divide at the centre and flow back and forth at both ends, *x* and *y* being silent because they are at neutral points, and *a* and *b* are not affected by the currents which flow through them because of the differential action referred to.

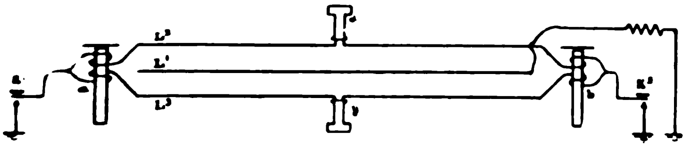

FIG. 7.

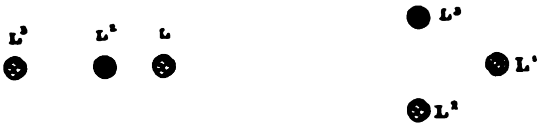

FIG. 8.

Two systems have been described, one in which the induced current is lateral, and the other in which it is longitudinal. I think it follows from the foregoing experiments, that where wires are twisted about each other as shown in Fig. 1, both of these actions are combined. At the left hand of Fig. 8, a cross-section of the three wires L^1, L^2 and L^3 [Fig. 1] is shown. In this position the wires occupy a place with reference to each other exactly as in Fig. 2, and the tendency of the disturbing wire is to cause a longitudinal flow in L^2 and L^3. If repeated cross-sections of these wires are made, a point will be reached at which the three wires are disposed as shown at the right hand of Fig. 8, where it is seen that the distributing wire L^1 is at an equal distance from L^2 and L^3, and the tendency is to produce a lateral flow. The actual currents produced must be the resultant of these two actions.

Fig. 9 shows a plan quite different in principle from anything heretofore employed. It is of interest not so much on account of any practical application which it may have at present, but because it is a very striking proof of the electrostatic nature of inductive cross-talk between telephone circuits. L^1, L^2 and L^3 are the same wires as used in the previous cases, L^1 being half an inch from L^2, with the addition of an extra wire L^4 placed half an inch from L^3 and joined by a conductor *w* with the disturbing wire L^1. L^2 and L^3 are three feet apart. When in this condition the transmitter is operated, no disturbance whatever is heard in the end telephones; if the wire *w* be disconnected, the usual noise is heard, but is found to disappear as often as L^1 and L^4 are joined together. This action is explained by the fact that L^4 is at the same potential as L^1, on account of being joined to it by the wire *w*, and acts with the same force on L^3 that L^1 does on L^2. The flow in this case is lateral, as indicated by the arrows; and the telephones are silent.

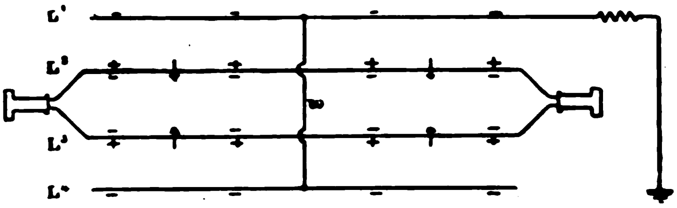

FIG. 9.

Neutral points may be produced in a circuit by the use of shunts. Fig. 10 shows the usual arrangement of circuits with the telephones *a* and *b* at the ends, and another telephone *x*, of equal impedance branched between the two wires at the centre. In this case four neutral points are found, two in each wire. The currents produced by the discharge are indicated by the arrows. Thus by the addition of one shunt, the disturbing currents in the end telephones have been reduced one-half. If similar shunts were placed at the quarters, the currents at the end telephones would be still further reduced to one-quarter of their original strength.

This plan is not a practicable one because of its shunting effect on the telephone current, but is of value as showing one of the actions which occur when instruments are bridged into metallic circuits. It is interesting to note that in Fig. 10 the telephone *x* is affected by a current twice as great as that which flows through either of the end telephones.

Before closing I shall describe one more experiment. In Fig. 11, L^1 is the disturbing wire and L^2 is a grounded telephone circuit placed one half an inch from L^1. At the centre of L^2 there is an ordinary telephone repeating coil or transformer C, containing two windings *e* and *f* of copper wire, each having a resistance of 160 ohms. One end of each winding is grounded, and the other end is connected to the line as shown. Assuming that the impedance of each telephone is equal to that of each coil of the transformer, a neutral point will be found at the centre of each half of L^2, and the disturbing currents flowing through the end telephones will be only half as strong as though the transformer were omitted. If now the connections of the transformer be reversed so that the discharges from the two sections of line pass through it in opposite directions, no magnetism will be produced in the core *k*, and consequently the transformer coils offer an easier path to the discharge. This causes the neutral points to move toward the end telephones and consequently reduces the disturbance still further.

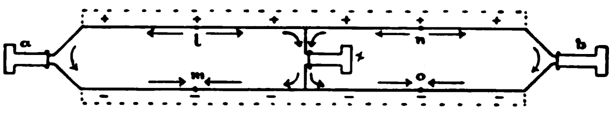

FIG. 10.

I have not had an opportunity of trying this experiment with a transformer whose coils contained a low copper resistance and a high inductance, but according to theory, we might expect that such a transformer having its coils connected differentially, should free a grounded line of considerable length from cross talk and other electrostatic disturbances. The number of such coils which can be worked in a given line is of course limited, but with properly designed apparatus a large number of them might be used. This arrangement is also interesting when considered with reference to electro-magnetic induction, and brings to mind a question as to whether we may not at some future time abandon the use of metallic circuits and again make use of Steinheil's discovery.

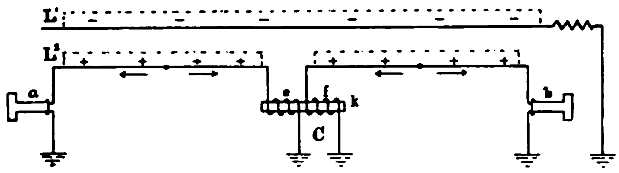

FIG. 11.

ON THE HEATING OF BRIGHT, FREELY SUSPENDED, COPPER WIRES BY THE CURRENT.[1]

BY U. BARBIERI.

IN order to calculate the rise of temperature of bright wires (suspended horizontally) by the current, there are various formulæ, those of Kittler, Uppenborn, Strecker, Sabine, &c. These formulæ give very different results, as the constants by which the ratio $\frac{c^2}{r^3}$ is multiplied in the formulæ vary between 0.1 (Sabine) and 0.03 (Strecker). The object of the present inquiry is to ascertain which of the existing formulæ express such rises of temperature with an accuracy sufficient for practical purposes, and, indeed, if any of them can be regarded as sufficient for all cases.

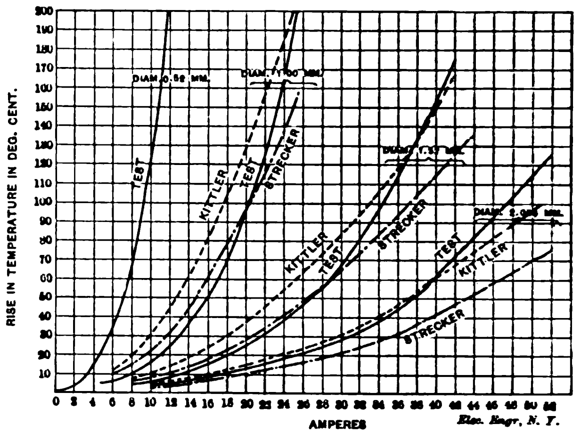
METHOD OF THE INVESTIGATION.

A wire about 7 metres in length is fixed securely at one end, and at the other it is carried over a pulley, the axle of which carries round with it synchronously a mirror. At the exact distance of 1½ metres from this rotating axle there is a scale, suspended vertically, which allows the values to be read off directly by means of a telescope.

At the end which passes over the pulley the wire is kept stretched by means of a weight equal to $\frac{1}{10}$th of the breaking strain as calculated from the section, etc. The temperature of the room is shown by three thermometers hanging near the wire.

Each wire was first overheated by a strong current in order that bends and other irregularities might be removed as far as possible. In the experiments the deflection of the mirror occasioned by the heating effect was observed. We calculated then from the radius of the pulley and the distance of the scale, the increase of length from which the rise of temperature is derived, by the aid of the coefficient of expansion of copper.

In order to be independent of the possible difference of materials as regards the coefficient of expansion, direct experiments on the thermic elongation of the description of copper used were instituted; rapid changes of temperature were effected by heating the room and then opening the windows (in winter).



RISE OF TEMPERATURE IN COPPER WIRES.

RESULTS.

Four copper wires (obtained from the firm Küstermann) of, respectively, 0.5, 1, 1.5 and 2mm. diameter were examined. The results are given in the accompanying table, and are represented by the curves. It appears from the numbers, that the so-called constant varies not only with the diameter, but that in one and the same wire it is not uniform with currents of different strengths.

Diameter of wire.	Strength of current.	Rise of temperature.	Constant.
0.52 mm.	3.2	10	0.0151
"	4.5	20	0.0154
"	6.2	40	0.0167
"	8.4	80	0.0176
"	9.8	120	0.0194
"	10 9	160	0.021
"	11.9	200	0.022
1 mm.	7.7	10	0.0206
"	10.7	20	0.0215
"	14.5	40	0.0228
"	18.6	80	0.027
"	21.3	120	0.033
"	23.5	160	0.036
"	25.7	200	0.0375
1.52 mm.	13.5	10	0.0234
"	18.3	20	0.0273
"	24.7	40	0.0275
"	32	80	0.0335
"	36.4	120	0.0371
"	39.5	150	0.0405
"	42	176	0.0420
2.004 mm.	14.5	5	0.024
"	19	10	0.027
"	25.2	20	0.031
"	33.7	40	0.036
"	39	60	0.039
"	43	80	0.043
"	47	100	0.046
"	51	120	0.047

If we take the mean values for the coefficient of the term $\frac{c^2}{r^3}$, their result, if we merely consider increases of temperature up to 100, we get the following numbers for the several diameters:—

Diameters.		Coefficients.
0.5 mm.	..	0.018
1.0 "	..	0.024
1.5 "	..	0.030
2.0 "	..	0.036

The formulæ of Kittler and Strecker are shown in the table of curves. We see that for thinner wires (1.0 and 1½) the former gives too high values between 0 and 100°; for a 2 mm. wire the theory agrees approximately with the experiments; it agrees closely with the increases of temperature which were observed in the 1 to 1½ mm. wires Both would probably show too slight rises of temperature, both for greater diameters and for higher strengths of current.

---

[1] *Elektrot. Ztschr.*

Since the conclusion of this investigation comprehensive results on the question have been published by Kennelly. Still the foregoing communication will not appear superfluous, because another direct method was employed, which renders the results independent of a knowledge of the galvanic coefficient of temperature of the single wires.

Kennelly's figures refer to thicker wires, from 2 mm. upwards, whilst here thinner wires from ½ to 2 mm. have been considered, so that the two investigations are complementary to each other. The observations on wires of 2 mm. in thickness which have been carried out in both, allow a comparison of the results, which shows a satisfactory agreement as it appears from the subjoined conspectus:

RISE OF TEMPERATURE.	5° C.	10° C.	20° C.	40° C.	80° C.
STRENGTH OF CURRENT.					
Kennelly ..	12,	18,	25,	35,	47.

THE ELECTRIC TRANSMISSION OF POWER.[1]

BY GISBERT KAPP.

THE lecturer commenced by explaining that before energy could be applied it must be transmitted, and that its transmission could be divided under two heads, the first being transmission over short distances measurable in feet or yards, and the second transmission over long distances measurable in thousands of feet or miles. The electric transmission of energy is generally used over long distances; the chief case in which it is employed over short distances is in the running of machine tools by means of electromotors which are supplied by dynamos fixed in the workshops.

The transmission of energy over long distances only was considered in the present lecture, and it was shown that it could be further divided into the two subdivisions of transmission of "live" energy by means of electrical conductors, wire rope, etc., and of transmission of "stored" energy by means of coal, corn, or falling water. The energy of falling water may be used to charge secondary batteries or to compress air, and the batteries or reservoirs of compressed air may be carried away, and the stored energy of the falling water may be transmitted to the place where it is required. It may easily be seen how corn may be carried from the field to a distance, and there used to feed horses, which will in return do useful work; or how coal may be taken from the pit's mouth to a distant city and there used to produce steam power. The value of any system for the transmission of stored energy depends upon the capital outlay and upon the working expenses, the latter in turn depending upon the storage efficiency, which is the ratio of the useful energy obtained at the end of the transmission, to the total energy absorbed by the system. The transmission of stored energy by the transport of secondary batteries was then compared with a similar transmission by means of compressed air, and the following results given:—

Total efficiency with batteries, 58 per cent.; weight of batteries, 100 lb. per horse-power hour.

Total efficiency with compressed air, 26 per cent.; weight of steel reservoirs and compressed air, 300 lb. per horse-power hour.

The transmission efficiencies of stored energy transmitted by means of coal, corn, or secondary batteries are given in Table III. Taking the case of the batteries and electromotor working on a tram line, it will be seen that if a car, itself propelled by the storage batteries it carries, is occupied in carrying charged batteries from the source of energy, say, a waterfall with generating machinery, to a distance, and taking them back when discharged, and the loss of energy in taking the batteries there and back is to be 10 per cent. of the energy originally stored in the battery, then the distance must be 10 miles there and 10 miles back, or 20 miles altogether. The distances given in the table are the theoretical distances, and are too great, as practically there would be considerable losses in inclines on the journey, and in starting and stopping; for these reasons the figures should be looked upon as merely approximations. From the table, it will be seen that the distance over which energy stored in coal can be transmitted with a given efficiency of transmission is enormously greater than the distance in the case of batteries. In the last column the coal transmission is no less than fifty times more efficient than the battery transmission. Besides the greater loss, the capital outlay for batteries is very large, and the depreciation 15 per cent. per annum. The figures in Table II., are based upon steam power at £10 per horse-power per annum, the steam power being used to generate the electricity for the batteries or direct mains. This table shows that for a transmission of 5 h. p., battery transmission costs more than "live" transmission by overhead conductors, but that it costs less than live transmission by underground conductors (except where the distance is about one mile or less). The cost of coal transmission for the distances mentioned in Table IV., would vary from £20 to £40 per annum per horse-power delivered. Where large steam engines are used at the end of large coal transmissions the cost per annum per horse power delivered will be about £10. Tables I., II., and VI., relate to the working of ordinary electrical passenger tramways where secondary batteries are used on each car and charged at particular charging stations.

The lecturer then went on to discuss the transmission of live energy from an electric light central station. In such a station the load due to the lighting varies greatly; during a few hours in the evening the station will probably be worked up to its full capacity, and then the production of electrical energy will be very economical, as all the capital outlay will be actively employed, and also the efficiency of the plant is greater when doing full work than when running light. During the early morning the load on a station may not be more than 10 per cent. of its full capacity, and during the daytime the output is very small; now, if, during these hours of minimum demand, the plant could be run at its full capacity, and the surplus energy distributed to electromotors, the working expenses would be only slightly increased, while the income of the station would be largely augmented.

In cases where motive power is required continuously, as, for example, in a small manufactory working 10 hours per day, or 3,000 hours per annum, it would not pay the manufacturer to use electrical power obtained from electric light mains, as compared with steam or gas power, unless it was supplied at 3d. or less per Board of Trade unit of 1,000 watt hours. Table VI. shows the connection between the cost per unit and the cost of a brake horse-power for 3,000 hours. To obtain his power from a small steam engine, the manufacturer would have to pay from £20 to £40 per brake horse-power for 3,000 hours, and the cost of the corresponding electrical energy supplied from electric light mains at 3d. per unit would be £33.5, as will be seen from the table. Now, the cost of a Board of Trade unit varies from about 4½d. to 12d., the average in London being from 7d. to 7¼d. But in many cases power is only required intermittently, and then electrical power is much more economical and convenient than steam or gas power.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER *150 Broadway, New York city.*

THE STATISTICAL REPORT OF THE N. E. L. A.

There is an incident connected with the Providence meeting of the N. E. L. A. which should receive a great deal of attention, but which apparently has been already forgotten.

THE ELECTRICAL ENGINEER stated, or rather had the courage to suggest, that the meeting might have been made of more practical value to those engaged in producing electricity for light and power purposes. Why such a suggestion, and to what does it refer?

In looking over the papers that have been read before the Association, as well as those which have appeared in the electrical journals, one is very forcibly impressed by the fact that every subject relating to the business has received due consideration, with one very important exception; also, that while the opinion expressed by the electrical fraternity, differs somewhat upon many subjects, it is unanimous on one thing, that is, *that nothing shall be said relating to "power."* I shall assume that the suggestion made by the ENGINEER, included among other things *the question of power.*

Without power what would become of the capital and people now interested in, and depending upon, the great electrical industries? Does the *economical* production of power bear no relation to the *cost of operating a station*, or are all stations operated in the most economical manner? If such is the case, then there is a great difference of opinion as to what economy means; for proof we will refer to the partial report offered by the committee on data at the last meeting of the N. E. L. A.

Some have an idea that economy depends upon the amount of red paint in the station, and the quality of the office furniture; others that it is expressed by the statement that so many pounds of coal are required per horse power per hour. As a matter of fact, the simple statement of itself means nothing, and may, or may not, be an expression of economy, depending upon other necessary conditions.

However, we will first look under that part of the report. We notice that the *consumption of coal* per horse power varies from 2.1 to 12 pounds per hour, that a compound triple expansion engine uses 10 pounds of coal, while a throttling slide valve engine works along with 5 pounds.

The number of pounds of steam used per horse power per hour is very interesting, and we notice a slight difference, as expressed by 17 and 90 pounds. As a singular coincident the last is credited to "Waterloo."

The apparent evaporation of water per pound of coal, varies from 5 to 17 pounds. Five pounds, while small, bears the stamp of truth, which is entirely lacking in the latter case; moreover, it is impossible to evaporate any such amount of water with a pound of coal.

We find various means resorted to to remove scale from the boilers, and to prevent its formation; a few antiquated ideas in the shape of *bark* and *potatoes* are not overlooked. In some cases vegetable matter will remove scale; the same elements, however, have played a prominent part in assisting more than one boiler to vacate the premises in a most unexpected and disastrous manner.

The temperature of the feed-water varies from *cold* to 225°; it would be of interest to know how the high temperatures were obtained, for if we take the temperature of *cold water* as 45° and steam pressure at 90 *pounds* by *gauge*, we shall save about 9 per cent. of our coal by heating the feed-water to 225°.

The expense for carbons and labor for trimming an arc lamp is about the same in all cases. Yet with a few, a consumption of 1½ pound of *coal*, and even less, will produce 1 h. p. or run one full arc lamp for one hour; many, however, see nothing out of the way in using 10 or 12 pounds to accomplish the same result.

Cases are common where the cost of carbons and labor for trimming, as well as the price received for the light, are the same; but in one case ten (10) times the amount of coal is used as in another.

One mistake occurs under the head of *non-electric companies*, to which attention should be called. A 1,140 h. p. compound condensing engine is charged with a consumption of 30,000 pounds of coal in 10 hours; it should have been 30,000 pounds used in 24 hours, besides furnishing steam for heating purposes.

The committee on data are in a position to prepare the most valuable report ever presented to the electrical interests, and one which will do more toward increasing the dividends and business, as well as improving the service, than all the previous work of the Association in that line.

It is to be hoped that no worse cases than those noted will appear; at the same time it is a satisfaction to know that a few are doing far better than any named in the report.

E. P. SPARROW.

BOSTON, MASS.

THE NOISE IN THE ARC.

By an article published this week in THE ELECTRICAL ENGINEER under the head of "Tesla's Alternating Generators of High Frequency," the sound emitted from alternate current arc lamps is attributed to the contraction and expansion of the gaseous matter forming the arc. I am presuming this is a surmise on the part of Mr. Tesla. His experiments, which are very commendable and, without doubt, effective, might be unnecessary if some other cause of the noise were known. My opinion is that it is primarily caused by the fluctuations in the electrical pressure, rather than by the frequency of its alternations, and that the lamps may possibly have some accidental magnetic responding construction, which keept time with the impulses of the dynamo, perhaps in much the same way as Gray's analyzers do in his harmonic telegraph, in which ribbons of metal under different tension respond only to a certain given number of electric impulses in a given space of time through the aid of corresponding magnets all in the same circuit.

In this connection I will recount some experiments I made a number of years ago which have influenced this opinion. I was experimenting with a one-quarter horse power motor on a Brush direct current circuit of about 3,000 volts. The motor was wound in series and its armature had nine Pacinotti projections. I found by holding the pulley on the armature shaft that the motor gave out the same sound as the dynamo, *i. e.*, a loud humming noise without any apparent motion. This noise increased as the projections on the armature were allowed slowly to approach the field pole pieces, and decreased as they were withdrawn. The maximum noise in this experiment was quite as loud as that from half a dozen alternate current lamps in the same room. I then repeated the experiment with a motor of the same capacity which had a smooth core, but could get no sound.

It appears to me that Mr. Tesla approaches the desired result by decreasing the size of his magnetic projections and increasing their number, thus insuring a smoother current, rather than from the effects of higher frequency. If this is true, the solution should be in having an armature core without projections.

Mr. Tesla asserts that higher frequency of alternations decreases the danger of the current. This statement is misleading. It is the height of the induced waves, rather than their number or length, that plays the mischief. In an experience of over four years in the construction and operation of dynamos and motors for railroad work, I dealt with 300 volt machines having coarse projections on their armatures. I have since learned that it was quite as easy to insulate smooth core machines to carry 500 volts, and I would prefer to handle the terminals of the latter; besides, I am not now inclined to dodge my telephone friends, as was formerly the case. My dynamo armatures had but six projections on their core and the same number of spider arms. They were the first compound machines ever used in railroad work, and they kept the potential more constant than any I have ever seen, but they had a habit of wearing the commutator sections opposite the projections much faster than the other parts. We were completely relieved of this trouble by changing the number of projections and corresponding spider arms from 6 to 9.

In speaking of projections on armature cores, I am aware that it has become the fashion of late to use them more particularly on railway motors and I am tempted to ask the question, Of what use are they? If the work performed is proportional to the number of magnetic lines of force passed through by the armature wires, of what benefit is it to short circuit a portion of those lines of force through the core projections?

JNO. C. HENRY.

New York, March 20, 1891.

PRIORITY IN CONVERTER DESIGNING.

In a letter published in The Electrical Engineer of March 4, on pages 287 and 288, Mr. James Swinburne, referring to certain advertisements of the Westinghouse Electric and Manufacturing Company, uses the following language:

"There is no reason why they should have any monopoly of high efficiency in closed circuits, as any other maker can use good iron and follow the principles laid down in my British Association paper. I am quite aware, of course, that a scientifically designed closed circuit transformer can give 95 per cent. efficiency, but advocates of closed circuit transformers should do me the justice to admit that this high efficiency is not due to them. Until my paper was read at the British Associatian in 1888, little was thought of the loss in iron. I there showed how closed circuit transformers should be designed to give 95 per cent. efficiency; and since then makers have reconsidered the proportions of iron and copper in their transformers. As far as I know, nothing had been said before about proportioning the iron so as to get small loss by hysteresis. The high efficiency closed circuit transformers have been produced by following the lines indicated in my paper."

Disclaiming any desire to detract in the slightest degree from the credit justly due Mr. Swinburne for his always suggestive and often valuable work, I, nevertheless, esteem it a matter of simple justice to others to say that Mr. Swinburne is under a misapprehension concerning the influence of his British Association paper upon the practice of "advocates of closed circuit transformers," in so far, at least, as the Westinghouse Company is concerned. The first transformers put upon the market by this company were designed in 1886, and before the end of that year some of them were in the hands of local companies. Early in the following year, that is to say, not later than the summer of 1887, a line of transformers comprising five standard sizes was designed by the electrician of the Westinghouse Company, Mr. O. B. Shallenberger, and the first of these transformers were turned out of the shop in September of that year. The proportions of iron and copper were not widely different from those existing in the transformers first introduced into commercial use, but some slight modifications were made. From that time to the present the general dimensions of these transformers have not been changed except in the case of the 10-light transformer, and in that, the proportions of iron and copper have not been materially altered. Several successive and important improvements have been effected but these have not been accomplished by radically changing the amount of iron or the amount of copper, nor have they been effected by following the lines indicated in Mr. Swinburne's paper. On the contrary, the amount of iron is, in the latest transformers, relatively greater than in the first ones of this type.

Mr. Swinburne refers to his paper upon the subject of the relative amounts of iron and copper in transformers as having been read before the British Association in 1888. I do not remember that the journals of that date reported the reading of any such paper at that time. Is it possible that Mr. Swinburne means to refer to his very interesting paper which was read September 16, 1889, at the meeting of the British Association at Newcastle-on-Tyne?

Assuming, however, that the date given for the reading of the paper is not a mistake, it is, nevertheless, certain that the standard transformers of the Westinghouse Company have not since been materially modified with respect to the proportions of copper and iron, and that, while Mr. Swinburne may be correct in the statement that "the high efficiency closed circuit transformers have been produced by following the lines indicated in my (his) paper,' those lines of practice were sufficiently understood by others before Mr. Swinburne was heard upon this subject.

L. B. STILLWELL.

Pittsburgh, Pa., Mar. 19, 1891.

The Central Thomson-Houston Company report business as very brisk in all departments. They have just closed several large deals for arc and incandescent plants, stationary motors and several extensive street railway contracts. Their isolated business is also very active and increasing all the time.

European Correspondence.

LONDON.

Anglo-German Cables.—National Telephone Co.—Mutual Telephone Co.—Granville's Electric Log.—Anglo-French Cable.—Telegraph Construction Co.—Vienna Electric Railway.

The disturbances of the system of telegraphic communications between England and Germany, which occur even in comparatively fair weather, are now to be remedied. At present only two cables exist between Emden and Lowestoft, but the governments of the two countries, urged by repeated complaints, have agreed to lay a third cable. Each government is to bear half the cost, which will amount in all to about £120,000. A bill on the subject will soon be laid before the Reichstag and the operations for laying the cable will commence immediately upon the money being granted.

The directors of the National Telephone Company, Limited, announced last week the issue of £350,000 four and one-half per cent. debenture stock, forming part of a total amount of new debenture stock which is limited to one-half of the subscribed share capital of the company for the time being, and redeemable at the option of the company on six months' notice at £110. The capital of the company is now £4,000,000, of which £2,494,920 has been issued. Notice has been given to pay off the existing debenture stock and bonds. The new debenture stock will then be constituted a first charge on the entire undertaking and property of the company.

The first Exchange of the Mutual Telephone Company was opened in Manchester, on Saturday morning last, when sixty-five subscribers were put in communication. It was originally intended to begin with a much larger number, but the dense fogs of the last fortnight by impeding overhead operations, rendered it impossible to connect a larger number. Wires are however ready for fresh subscribers who will be added day by day until the full complement is supplied. I have previously mentioned that the object of the Mutual Telephone Company is to provide exchange communication of an improved character and at rates not exceeding £5.10s. a year. On account of the Edison patent, transmitters of the magneto type made by Siemens & Co., of Berlin, are used, but will be replaced by carbon ones in July, when the patents expire.

Granville's electric log, made by Messrs. Elliott, of London, is said to obviate many of the difficulties which exist in a ship's recording apparatus. Essentially an electric log, it however has no battery whatever, the log, the iron hull of the ship and the ocean together forming the battery. A portion of the log is made of zinc, which provides one element, while the iron plates of the ship form the other, the sea water constituting the exciting solution. The log is of very simple construction and has only two moving parts, a revolving head and a small internal worm wheel. The head is connected with the worm wheel gearing, and every sixth revolution of the former is communicated by means of a spring contact, through the tow line to an indicator placed on the bridge or in the chart house of the ship. When the log is in use the sea water has free access to all the working parts, and serves to keep them clean and lubricated. The tow-line which is very pliable, is made of a braided tanned netting twine, inside which a number of copper wires are wound spirally and joined together at each end. This line can be handled and coiled by a sailor in the same way as any other line, and is readily connected with, or disconnected from the log. The indicator consists of a small metal circular box with the necessary internal mechanism and external dials and pointers. The apparatus, after many months' trial at all speeds, has shown itself to be an efficient means of accurately indicating, at any part of the ship where an indicator is fixed, the total distance run, and also, at any time, the rate of speed per hour. One of these logs has been fixed on board the Orontes, and it is also in use in the Argentine Navy.

The submersion of the Anglo-French telephone cable will take place to-morrow (Thursday), and it is intended to proceed on Monday with the practical experiments, and if these are successful the cable will be opened on the 15th of this month. No privileges are to be granted to private subscribers or to newspapers. In Paris, subscribers will be permitted to correspond from their houses directly with London, but in London, communication will be made from the public telephone offices.

The Telegraph Construction and Maintenance Company, Limited, which held an annual meeting yesterday, is in a most flourishing condition. After paying 20 per cent., over £65,000 has been carried to reserve fund. Over 9,000 miles of telegraph wire has been insulated, and 4,000 miles of wires laid.

The Hungarian Minister of Commerce has rejected the petition for the concession of the electric railway between Vienna and Budapest.

H. S.

London, March 4, 1891.

Society and Club Notes.

FRANKLIN ELECTRICAL SOCIETY.

The meetings of this society, S. Cohen, corresponding secretary, will hereafter be held on the second and fourth Saturdays of the month, at 8 P. M. The next meeting will be held Saturday, March 28, at 8 P. M., at the rooms, 239-241 East 57th street, when an elementary paper on "Electric Traction" will be read by Mr. L. Newman. Visitors are invited to attend.

NOMINATIONS AT THE NEW YORK ELECTRIC CLUB.

At the annual nominating meeting of the Club, held at the Club House, Tuesday evening, March 17, officers for the ensuing year were nominated as follows:—*President*, O. E. Madden; *vice-presidents*, Samuel Insull, Chas. W. Price, Erastus Wiman and W. D. Sargent; *secretary*, Frank Z. Maguire; *treasurer*, Geo. B. Coggeshall; *board of managers*, H. L. Shippey, Dr. J. B. DeLery, P. H. Alexander, H. D. Cheever, T. C. Martin, C. D. Shain, C. E. Stump, Joseph Barré, E. F. Peck, C. O. Baker, Jr., E. E. Bartlett, H. D. Stanley, J. H. Herrick; *committee on membership*, C. H. Barney, Geo. T. Manson, J. C. Chamberlain, S. S. Wheeler, Joseph Wetzler.

THE MAGNETIC CLUB.

This club has just begun the practice of making printed records of its meetings. The first issue is very interesting and contains some personal reminiscences of President Lincoln by Mr. A. B. Chandler, the inaugural address of Mr. Edward C. Cockey as president of the club, and some manly advice to the younger members of the telegraphic profession, by Mr. G. G. Ward.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the Council, held on March 17, the following gentlemen were admitted to associate membership:

Greenberg, Adolph G. Salesman, Fort Wayne Electric Co., 115 Broadway, New York City, 90 Pierrepont St., Brooklyn, N. Y.
Harrington, Walter E. Managing electrician, Atlantic City Electric Railway, Atlantic City, N. J.
Tuttle, George W. Storekeeper, Sawyer-Man Electric Co., 510 West 23d St., New York City.

At the regular monthly meeting which followed at 8 p. m., Mr. J. J. Carty, the electrician of the Metropolitan Telephone & Telegraph Co., read a very interesting and suggestive paper on "Inductive Disturbances in Telephone Circuits," which was followed by an animated discussion on the subject.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Mr. A. J. Corriveau, of Montreal, was in New York last week making further arrangements for the meeting of the National Electric Light Association in Montreal next August. The Windsor Hotel will be the headquarters of the convention and a large exhibit of electrical goods and apparatus will be made in the Victoria Rink adjoining. Local committees are already being organized, and there is promise of hearty interest and cordial hospitality in every direction. The Canadian papers are devoting their space liberally to the matter, and the indications are already numerous that the convention will not only be a delightful summer episode, but an occurrence productive of the greatest benefit to both countries.

ELECTRICAL PROGRESS IN 1890.

The next regular meeting of the New York Electrical Society, on Friday, March 27, at 8 P. M., will be held by kind invitation at the Electric Club, No. 17 E. 22nd street, this city.

Mr. Joseph Wetzler will deliver a lecture on "Electrical Progress in 1890," in which he will devote particular attention to the practical advances which have been made during the past year.

The meeting will be one of special interest, due to the fact that many prominent inventors will be present to describe in person, and with the aid of models, the improvements made by them. Among the inventors who will assist, we may mention Nikola Tesla, P. B. Delany, J. C. Chamberlain, J. J. Carty, C. O. Mailloux, F. J. Patten, J. C. Henry, Dr. W. E. Geyer, W. H. Bristol, G. W. Walker, F. B. Crocker, and others. The lecture will begin promptly at 8.

The subjects touched upon will embrace the departments of Electric Lighting, Continuous and Alternating Motors, Thermo-Magnetic Generators, Telegraphs, Telephones, Electric Measurement, Primary and Storage Batteries, Electric Railroading, etc.

PITTSBURGH ELECTRIC CLUB.

Our Pittsburgh correspondent writes us that the electrical people of that city held a meeting on Thursday, March 19, and carried out a scheme that has been under discussion for some time, in the organization of an electric club.

The subjoined officers and board of directors were elected: President, Morris W. Mead; treasurer, James A. Rutherford; secretary, J. E. Hall; directors, H. McL. Harding, D. W. Dunn, I. H. Silverman, E. B. Kittle, H. E. Dillon, E. Ingold and E. B. Gawthrop. The organization was completed and a committee was appointed to take in hand the matter of securing a charter.

DEPARTMENT OF ELECTRICITY, BROOKLYN INSTITUTE.

The regular monthly meeting of the Department was held on Friday, March 20th, when, before an audience of 200 members and visitors, Mr. E. H. Cutler, the general manager of the Elektron Co., delivered a most interesting and instructive lecture on "Electric Motors and Their Construction." Mr. Cutler dwelt with much emphasis and force upon the essential features of lamination and slow speed, and illustrated their importance very clearly. He also accompanied his lecture by diagrams and by details of the materials employed in motor construction. He made an excellent display, too, of the Perret motors in various sizes up to 4 h. p. and showed how readily they lent themselves to every class of work necessitated by modern industry. The lecture was followed with the closest attention, and was one of the best of the admirable series with which the Department has gratified its members this season.

Patent Notes.

ELECTRIC SNAP SWITCH.

The issuance of a patent to E. H. Johnson, entitled "Electric Switch," No. 448,431, March 17, 1891, filed March 27, 1885, terminates one of the most hotly contested patent applications witnessed in the U. S. Patent Office. This patent is said to have had more interferences declared on it than any other ever before in the office. It is claimed to cover substantially any switch for controlling electrical circuits in which a spring is put under tension by the movement of the handle, and when the tension is at the maximum point acts upon the moving contacts independent of the handle and throws the moving contacts in one direction or the other with a quick powerful movement. This is the principle embodied in a large number of snap switches now in general use. It is understood that Mr. Johnson intends to enforce his rights in the matter.

THE CROWDED STATE OF THE PATENT OFFCE.

A special dispatch to the *Evening Post*, from Washington, of March 12, says:—In view of the overcrowded condition of the Patent Office, to which reference has been made previously in these despatches, the project has been mooted lately of destroying a large share of the copies still preserved of the older patents, so as to make room for the new ones. Commissioner Mitchell is reported to be somewhat impressed by the suggestion. From other sources, however, comes the strongest opposition. Patent attorneys and inventors all over the country are continually sending in their requests for copies of old patents, not merely individually, but as parts of sets concerning certain special subjects. To destroy these old copies in any quantity would cripple the office in its efforts to supply such demands; and in case the run upon any class of patents became large, the Government would be put to the expense of reprints. Finally, there seems to be no legal authority for the proposed destruction. The law requires the printing of a certain number of copies of each patent, and the sale of these copies at a specified price, but nothing is said of the right of the Commissioner of Patents or any one else to destroy them; and in other Government bureaus, where a surplus of old papers has accumulated, the custom is to wait until a committee of Congress has condemned them and ordered them sold or destroyed.

The appropriation made by the last Congress for rent of quarters for the Land Office outside of the Patent-Office building is likely to fail of its intended effect, as the owners of the building in which the new offices were to be procured have refused to rent to the Government. Even in case outside space can be procured as desired, it is doubtful whether the land office will be forced, as it should be, to remove any considerable part of its present machinery wholly out of the Patent-Office building and leave room for the Patent Office to spread; or whether it will simply stretch itself out so as to occupy all its present space and the new quarters besides. The policy on which the Interior Department has been managed for years has been to give more and more latitude to the Land Office and crowd the Patent Office into a smaller and smaller corner, and the friends of the last-named bureau have become discouraged at the outlook.

Reports of Companies.

TRINIDAD-HEIMANN INSULATED WIRE CO.

Mr. J. O'Rourke has been appointed receiver of the Trinidad-Heimann Insulated Wire Co., of Liberty street, this city. The company has been endeavoring to carry on the business established by the old Callender Co., but has not done a large trade.

EUROPEAN WELDING CO.

The purchasers of the welding patents for Europe have agreed to pay $25,000 to have the time for final payment of the purchase money extended 60 days from March 1.

A BIG EDDY POWER TRANSMISSION PLANT.

The Eddy Electric M'f'g Co., of Windsor, Conn., has just closed a contract with the American Encaustic Tiling Co., Limited, of Zanesville, Ohio, for an electric power transmission plant aggregating 365 horse power. The dynamos will be 90 h. p. each, and the motors will range in size from 10 to 35 h. p.

THE ATLANTIC AND WESTERN TELEPHONE CO.

The Chicago *News* of March 18 has the following:—"The Atlantic and Western Telephone Company, incorporated yesterday with a capital stock of $5,000,000, proposes to utilize the patents taken out by Henry C. Strong, who claims to be the original inventor of the instrument. Strong has been a telegrapher and electrician for many years. He says that in 1875 he perfected an instrument upon exactly the same working principle as the one used by the Bell company. In 1877 he applied for a patent, but the department would not recognize his claims and he lacked the capital to push them. Since 1877 he has been seeking recognition, but he has lacked money to fight the powerful monopoly which secured the patent. At one time he had established several private lines in Chicago and had manufactured twenty-five receivers, all of which were forcibly seized by agents of the Bell company.

"Mr. Strong claimed and still claims a prior right to the invention, and he has interested several people who have faith in his claim. Lately he succeeded in getting a patent on a modification of his original telephone, and it is this instrument which the new company will manufacture. It proposes to do a general business and will maintain the right to use the patent now claimed by the Bell company.

"Henry P. Caldwell, George M. Porter and Edward B. Springer, of Chicago, and George M. Brinkerhoff, of Springfield, are interested in the new corporation."

DIVIDENDS.

THE THOMSON-HOUSTON ELECTRIC CO. has declared a dividend of $2.50 per share on series C. securities, payable March 18.

THE AMERICAN BELL TELEPHONE CO. has delared a dividend of $3 per share payable to stockholders of record March 26.

ELECTIONS.

NEWARK, N. J.—At the annual meeting of the stockholders of the Newark District Telegraph Company, directors were elected for the ensuing year as follows: T. T. Kinney, George W. Hubbell, F. T. Feary, W. C. Ward, E. Weston and Enos Runyon.

NORWALK, O.—At the annual meeting of the Norwalk Light and Power Company, John Young, of Chicago, was elected president; George Barney, of Sandusky, vice-president, and W. M. Carpenter, of Chicago, secretary and treasurer.

GLOUCESTER, MASS.—The sale of the Gloucester Street Railway was completed on the 9th instant, when the stock was formally transferred, and the following directors were elected: W. B. Ferguson, of Boston; Col. J. H. Cunningham, president of the Winnisimmet National Bank, of Chelsea, and Mayor A. D. Bosson, of Chelsea. Mr. Ferguson was elected president and Col. Cunningham vice-president and general manager. President Ferguson states that the new management will enlarge and improve the service. The main line will be equipped with electricity immediately. The scheme of extending the road has not been completed, but a line to Lanesville, a distance of seven miles, will doubtless be built this summer, and other extensions may be made.

FALL RIVER, MASS.—At the annual meeting of the Fall River Electric Light Co., the following officers were elected for the ensuing year: Clerk and treasurer, Owen Durfee; directors, F. S. Stevens, J. D. Flint, W. H. Hathaway, E. L. Anthony, F. O. Dodge, O. S. Hawes.

The financial statement was as follows:

ASSETS.	
Construction accounts	$84,620.84
Cash and accounts	7,834.84
Miscellaneous	32,487.43
	$124,743.11

LIABILITIES.	
Capital paid in	$102,200.00
Bills and accounts payable	20,739.87
Profit and loss	1,803.24
	$124,743.11
Receipts, all sources	$31,989.88
Expenditures	24,118.94
Net earnings	$7,870.94

STOCKS AND BONDS.

ST. LOUIS, MO.—The stockholders of the East St. Louis Electric Railway Company met last week and voted to issue $15,000 of 5-15 bonds bearing 6 per cent. interest. The main line has already been completed and has done a paying business since the opening day. The branch line to the Little rolling mill is being rapidly constructed.

SAVANNAH, GA.—A meeting of the stockholders of the Ft. Meade, Midland and Avon Park Telephone Company was held at Avon Park recently when the company was organized and the following board of directors elected: E. W. Dawson, Geo. Edmiston. W. A. Evans, J. C. Burleigh, John C. Williams. The stockholders decided, by unanimous votes, that the capital consist of forty-five shares, of $25 per share, and that the directors be instructed to make a contract to finish the line at once. The following officers were elected: E. W. Dawson, president; Geo. Edmiston, vice-president; W. A. Evans, treasurer; J. C. Williams, secretary. The line is in process of construction.

OGDEN CITY, UTAH.—The Ogden City railway was sold at trustee's sale on March 5th. The price realized was $85,000, and it was bid in by L. R. Rhodes through H. M. Beardsley, attorney for the Jarvis-Conklin Mortgage Trust Company, of Kansas City, Missouri. The original debt of the road was $80,000, held by the Jarvis-Conklin company, who not only have borne the running expenses of the line, but have expended a large amount of money in equipping it with electrical appliances. About six miles of wires have been placed in position on the most important streets. Other improvements will be made as soon as the condition of the streets permits. A large power house will be built at once. Mr. Rhodes has been given temporary charge of the lines.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of March 21, 1891, from New York, Boston and Washington; Pittsburgh, March 20.

Legal Notes.

W. U. NOT RESPONSIBLE FOR LIGHTNING.

In the damage suit of Albert J. Angus against the Western Union Telegraph Company, at Superior, Wis., a verdict for the defense of no cause of action has been returned. This was a suit brought by Angus as a result of a stroke of lightning received by the plaintiff while running a hotel at Pike Lake eighteen months ago. The company had an office in Angus' hotel, and when the instruments were taken out, failed to ground their wires. Angus set up the allegation that the wires attracted the heavenly fluid to his havoc. The case has attracted the attention of electricians and telegraph officers all over the country.

THE RESPONSIBILITY OF TELEGRAPH COMPANIES.

In the case of Luke M. Emerson against the Western Union Telegraph Company for damages under section 2,725, revised statutes of 1889, Judge Hughes, of the Pike county circuit court, Missouri, has rendered a decision which, if sustained by the higher court, invalidates the statute. Emerson sued for the penalty of $200 for the failure of the company to deliver a telegram sent from this city to Nashville, Ill. The defendant demurred on the ground that said section so far as it applies to telegraphic business beyond the borders of Missouri is unconstitutional in that it undertakes to regulate interstate commerce, and is, therefore, in violation of the constitutution of the United States, conferring on congress the regulation of interstate commerce. Judge Hughes sustained the demurrer. As the principle involved in the case is of great importance, Clark & Dempsey, the plaintiff's attorneys, will take the case to the higher courts, and ultimately to the supreme court of the United States, if necessary.

ALLEGED UNJUST TAXATION IN VERMONT.

Persons who are interested in some of the smaller telegraph lines of Vermont are complaining of an injustice done them by the Legislature of the State in assessing them, under the corporation tax law, 10 per cent. of their gross receipts, when telephone companies are assessed but three per cent. They assert that the telephone companies are making more money than the smaller telegraph companies, and that the tax imposed upon the telegraph companies is outrageous. The law is made retroactive, and the tax is assessed upon business done since June 30, 1890.

ST. LOUIS, MO.—The Adams Electric Company, incorporated under the laws of Illinois, with a capital of $5,000,000, has perfected its organization by the election of W. Slaughter as president. The company proposes to enter suit against all the street railroad companies infringing on the Adams patents. The first suit will probably be brought in Boston. Eminent counsel is retained and an attempt will be made to wrest the patents from such corporations as the Thomson-Houston, Van Depoele, Bentley-Knight, Westinghouse, Short and Wenstrom.

Should the Boston suit be decided in their favor the Adams Company will then obtain writs of injunction restraining all other companies from use of the patents.

TUNNEL LIGHTING BY ELECTRICITY.

At the investigation of the accident in the Fourth Avenue tunnel, last week, Mr. Augustus Whiting, who had examined the manner of illuminating the Hoosac Tunnel, testified that he had passed through that tunnel on a locomotive and found that, owing to electric lights placed forty feet apart, and about five feet above ground, it was as bright as day. There were 1,250 of these lights, and, owing to the fact that coke was used in the engine furnace, the atmosphere did not become murky at all. He could always see a long distance ahead.

Engineers with whom he conversed told him that while the company had fought against the system at first, it was now admitted to be perfect, and no accidents had happened since it had been put in. The cost was about $30 per diem.

An engineer running a locomotive on the Harlem road was called, who testified that the street electric lights at Motthaven blinded him. He did not mention, however, that those are arc lights, while the lamps in the Hoosac Tunnel are incandescents.

BOOK NOTES.

The Cassell Publishing Co. is issuing a new work by Mr. Robert Grimshaw, the engineering expert, entitled "Hints to Power Users." It will contain a large amount of valuable information as to selecting, buying, placing and operating every part of a power plant, and touches on all the many details of such an installation. It will be published at $1.00.

Appointments, Etc.

MR. F. SARGENT, of Chicago, has been selected by Commissioner Barrett, as his electrical engineer for the electrical department of the Columbian World's Fair. Mr. Sargent has had a long experience as a marine engineer and later as one of the engineers of the Edison General Co. He has lately been in practice for himself in Chicago, as a consulting steam and electrical engineer.

MR. C. STEWART HUNTER has severed his connection with the New York Safety Insulated Wire & Cable Co., and joined the forces of the Bishop Gutta Percha Co.

PRESIDENT DUNSTON, of the Connecticut Motor Co., has been made general superintendent of the Thomson Electric Welding Co., at Lynn, Mass.

MR. C. K. WESTBROOK, manager of the Thomson-Houston isolated lighting department, in Philadelphia, has been given charge of the business of the Thomson-Houston Motor Co., with headquarters at 509 Arch street. Mr. E. D. Mullen has been put in charge of the railway department at the same address.

MR. FRED E. ALEXANDER, one of the best known electrical experts in New England, has connected himself with the Eastern Electrical Supply and Construction Co., 65 Oliver street, Boston. He will have charge of the central station department of this company.

MR. JOHN KENYON has returned to Philipsburg, Pa., to take charge of the electric light and steam heat plants in that place.

Personal.

MR. FRED CATLIN.

One of the best known telegraphers in the country is Mr. Fred Catlin, who has just resigned his position as chief operator of the Eastern Division of the W. U. Tel. Co., in New York, to take up the management of The Newspaper Press, which is an association for collecting and selling news. Mr. Catlin has a very creditable telegraphic record behind him, and is known as one of the best and swiftest operators ever seen in America. His method of handling the key is known as the "Catlin grip," and has long been approved by the most experienced men in the craft. Mr. Catlin has also made a phenomenal success of his Telegraphic Tournaments, the last of which will still be fresh in the minds of our readers. The Newspaper Press, we may mention, is backed by the Globe Press Association, a "plate matter" concern, of which Mr. W. J. Arkell, of the *Judge*, is president. The Newspaper Press being primarily the telegraphic arm of the Arkell Company, it may expect sufficient revenue at once from that concern to put it on a solid footing and enable it to push forward free from the handicapping that similar organizations have usually encountered at their outset.

UNSUSPECTED MERIT OF THE TROLLEY SYSTEM.

The recent strike of cloakmakers in New York city, and the attending troubles at Jamaica, L. I., have resulted in one good thing for the overhead trolley system. A lot of the riotous union men descended on a "scab" contractor at the latter place, and after wrecking his shop and throwing vitriol on his wife and child, decided to hang the contractor to an overhead trolley wire, and only gave up their plan when they discovered that the current was not strong enough to injure him. Those of them in the habit of reading the daily papers had been deluded into the belief that the railway current would reduce their victim to a state of innocuous desuetude more quickly than vitriol would. They know better now.

TELEPHONING BETWEEN LONDON AND PARIS.

The inaugural telephone talk between London and Paris by the new land and sub-marine cable line on March 18 was a notable event. Mme. Roche, wife of M. Roche, Minister of Industry and the Colonies, had the honor of uttering the first words over the new line. M. Roche then held a conversation with Mr. Henry Cecil Raikes, the Postmaster-General of Great Britain. M. Roche said that he hoped the telephone line would form a fresh link of friendship between Great Britain and France. The Earl of Lytton, the British Ambassador at Paris, and M. de Selves, the Director-General of the Posts and Telegraph Department, also spoke to Mr. Raikes by telephone. The results are very satisfactory, the talking being quite clear and audible.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 17, 1891.

Alarms and Signals :—

Call System, L. Digeon, 448,322. Filed Nov. 1, 1887.
Adapted for fire alarm, police or any other call system. Includes the use of telephones.

Barber's Indicator, S. P. Watson, 448,392. Filed June 7, 1890.
Details of electro-magnetic and mechanical devices.

Clocks :—

Electric Alarm Clock, E. M. Edgerton, 448,325. Filed Nov. 21, 1889.
Details of construction and circuits.

Circuit Closer for Clocks, H. A. Chase, 448,291. Filed Sept. 6, 1889.
Employs means for causing a large amount of surface of one member of the circuit closer to make contact with the other member of the circuit closer in a short space of time ; a sliding or rubbing contact is employed.

Conductors, Conduits and Insulators :—

Insulator, G. K. Wheeler, 448,395. Filed Nov. 21. 1890.
A cone insulator consisting of two non-conducting portions, the upper being cone-shaped to receive a hood ; the two portions are screwed together and each carries a metal hanger, one projecting above the cone-shaped part and the other below the hood.

Electric Cable, W. A. Conner, 448,604. Filed Nov. 8, 1890.
Consists of a number of conductors each covered with a fibrous insulating material, grouped to form a core which is provided with water-proof covering and a sheathing capable of withstanding a high temperature, and an exterior protective coating of lead.

Distribution :—

Electric-Lighting System, E. Thomson, 448,279. Filed May 21, 1886.
Relates to means for automatically regulating the flow of current to translating devices arranged in multiple arc upon a line on which the current supplied is of nearly uniform amount, such as an arc-light circuit supplying a number of groups of incandescent lights in series. Consists essentially in the combination of an electro-magnet adapted to move its armature step by step with definite changes in the strength of the magnet, and so connected as to be in derived circuit around the lights, with means whereby the successive movements of the armature introduce definite resistances equal to the number of lights that may be extinguished by accident or otherwise.

Dynamos and Motors :—

Method of and Apparatus for Developing Mechanical Motion From Electrical Energy, R. Eickemeyer, 448,326. Filed July 20, 1888.
An electric motor without commutators. Resembles Fonvielle and Lontin's "tourniquet electrique."
Claims 1 and 10 follow :
1. The method of developing mechanical motion from electrical energy, which consists in intermittingly varying the polar conditions of an electro-magnetic field and in like manner varying induced polar conditions in a movable element by correspondingly varying separate supplies of field-exciting energy derived from any suitable source of electricity.
10. In an electric motor, the combination, substantially as hereinbefore described, of a magnetizable armature, an electro-magnet having separate sets of exciting helices coupled to separate electric circuits, and means for separately supplying electric energy to said helices under impulsive conditions and causing said sets of helices to successively and alternately develop variable polar conditions in said magnet and to sequentially develop in the armature correspondingly varied but opposite polar conditions.

Commutator Brush, K. G. Frietsch, 448,331. Filed June 28, 1890.
Has a carbon or other suitable contact piece, automatically fed forward as it wears away by an adjustable spring pressure ; the current passes from the carbon contact near the commutator surface to a second brush of copper or other good conductor.

Commutator-Truer, D. McGenniss, 448,540. Filed June 10, 1890.
An appliance for trueing or rectifying commutators.

Electro-Magnetic Motor, E. D. Chaplain, 448,608. Filed Aug. 21, 1889.
Mechanism designed to facilitate the adaptation of electric motors to driving individual machines in a factory or to drive a line of shafting ; armature arranged to revolve about the axis of a central shaft ; comprises a system of differential of gearing.

Driving Mechanism for Dynamo-Electric Generators, S. H. Short, 448,308. Filed Nov. 6, 1890.
Specially adapted to driving dynamos that are coupled directly to the engine. The dynamo is mounted on an insulated base. The driving shaft is in two parts rigidly connected together, one supported on the engine and the other carrying the armature ; the two parts of the driving shaft have an insulating section between them.

Lamps and Appurtenances :—

Electric Arc Lamp, J. W. Easton, 448,418. Filed March 20, 1890.
A brake wheel controls the movement of the carbon rod and a spiral spring bears against the periphery of the brake wheel ; one end of the spring being secured to a fixed portion of the frame and the other end being connected to the core or armature of a solenoid or magnet. The tension of the spring varies with changes in the resistance of the lamp circuit.

Electric Arc Lamp, K. Kurmayer, 448,351. Filed Sept. 15, 1890.
Details of design and construction of an arc lamp employing carbons converging or in an angular position with each other.

Measurement :—

Electric Meter, E. Thomson, 448,280. Filed Nov. 20, 1890.
For registering the current in a constant potential circuit. A motor meter in which movement is retarded by a copper disc or equivalent closed circuit conductor rotating in a magnetic field of varying strength. The field is so proportioned to the torque of the motor that when no translating devices are in circuit the damping effect will suffice practically to stop the movement of the motor.

Miscellaneous :—

Electric Sad Iron, C. E. Carpenter, 448,317. Filed June 21, 1890.
Designed to confine the heat to the working surface ; employs a heat insulating material between the body and plates.

Support for Electric Wires, C. A. Lieb, 448,216. Filed Nov. 19, 1890.
An insulated supporter for overhead wires particularly adapted for trolley-wires. Comprises a metallic body part and a metallic nut within and between insulating material and a threaded ring engaging with threads on the body part for holding the insulating material in place.

Electric Type-Writing Machine, E. J. Silkman, 448,271. Filed April 7, 1890.
Employs electro-magnetic apparatus for reciprocating the actuating-frame and turning the type-wheel.

Electrically Controlled Valve, J. V. Stout, 448,273. Filed Jan. 31. 1890.
Relates to devices of the class in which a thermostatic circuit-closer is employed with electro-magnetic apparatus for controlling a heating medium.

Electric Temperature-Regulator, J. V. Stout, 448,274. Filed Jan. 31, 1890.
Similar in purpose to the next above.

Segmental Resistance-Board, G. D. Hand & O. P. Sells, 448,338. Filed Aug. 11, 1890.
Relates to segmental switch-boards for controlling electric lights in theatres and other public places, and designed especially for compactness and convenience of manipulation.

Support for Electric Cables, H. B. Nichols, 418,359. Filed Nov. 15, 1890.
A clip or clamp for affixing and supporting electric cables upon the walls of buildings or on any other fixed support.

Electric Switch, R. D. Pratt, 448,365. Filed July 7, 1890.
A switch operated by a push-button, which is pressed both to open and close the circuit ; shown in the patent as adapted to an electric lamp-socket.

Vapor-Engine, D. S. Regan, 448,369. Filed Nov. 6, 1890.
Employs electricity for igniting the gas or vapor.

Electric Switch, E. H. Johnson, 448,431. Filed March 27, 1885.
Claim 1 follows :
A hand-switch for making and breaking an electric circuit having, in combination, a moving contact-piece, a spring connected with said moving contact-piece by a loose connection, and a free handle connected with such spring and acting by its movement to strain the spring and to release it without making or breaking the circuit, whereby the spring will then throw the moving contact-piece by direct spring action to the end of its movement, and the circuit will be made or broken by a spring-snap action.

Electric-Wire Support and Cut-Out, E. R. Whitney, 448,468. Filed Nov. 4, 1890.
A wall or ceiling support and cut-out.

Method of Making Plated Wire, C. R. Smith, 448,594. Filed Dec. 24, 1890.
Deposits electrically upon a metallic rod a thin film of another metal, then places upon the electro-plated rod a metallic shell, then subjects the whole to heat sufficient to fuse the electro-deposited metal, thus soldering the shell to the rod; then reducing the rod to a wire.

Railways and Appliances :—

Electric-Motor Truck, F. O. Blackwell, 448,199. Filed June 17, 1889.
Claim 1 follows :
The combination, with an electric motor having a framing journaled upon the axle of a vehicle and carrying gears connecting the armature shaft with the axle, of a framing independent of the car body attached to the journal boxes of the truck outside of the wheels, supporting the free end of the motor and provided with a cushion modifying its action upon the journal boxes.

Motor-Suspension for Railway Work, E. W. Rice, Jr., 448,260. Filed Aug. 15, 1889.
Consists, chiefly, in the provision of a frame sleeved to the car-axle and having journal-bearings for the armature axis and the axes of any intermediate gear between the armature and car-axle ; the motor field-magnet is supported on the armature axis.

Tail-Light for Railway-Trains, A. W. Berne, 418,315. Filed Mar. 14, 1890.
A metal arm on the axle of a car and rotating with it makes and breaks circuit for flashing the tail-light, thus indicating whether the train be moving or no.

Electric Railway, J. B. Entz, 418,328. Filed July 3, 1890.
Consists chiefly in the employment of a continuous stationary armature extending throughout the length of the track ; field-magnets carried by the car in proximity to the continuous armature are energized by the armature, through brushes or other contact devices. The car or vehicle is thus pulled directly by a horizontal force.

Electrical Street and Station Indicator, F. H. Soden, 418,378. Filed Mar. 20, 1890.
For street and other railway cars. Source of electricity carried upon the car. A trolley suspended from the car is operated at desired points along the line for closing and opening circuits to the electro-magnetic indicator.

Underground Conduit for Electric Railways, R. A. Stewart, 448,461. Filed Oct. 4, 1890.
Has a slot extending sidewise into the conduit for the passage of the trolley arm ; designed to prevent the access of mud or other obstruction to the trolley contacts ; the trolley or brush bears upon the under surface of a conductor secured to the upper inner surface of the conduit.

Electric-Railway Motor, C. J. Van Depoele, 448,561. Filed Oct. 22, 1889.
The motor comprises a stationary part or field which is annular or cylindrical in form with a continuous iron core. The armature is shown as directly upon the car axle. The invention includes means for distributing supply current to the motor or motors.
Claim 15 follows :
The combination, with a moving vehicle or vehicles, of one or more motors applied to propel the same, means actuated by the movement of the vehicles for distributing supply current to the motor or motors, and a series of motors all supplied by a distributer or distributers controllable from a single point, and a single set of reversing apparatus for the entire series.

Electric Locomotive, C. J. Van Depoele, 448,562. Filed May 26, 1890.
Claim 1 follows :
An electric locomotive comprising the two independent axles of a car truck, a single motor disposed between and separately spring supported upon said axles and provided with a suitable pinion upon its armature shaft, and dynamometric gears on each axle, said gears being all in direct engagement with the armature pinion.

Electric-Railway System, C. J. Van Depoele, 448,563. Filed Dec. 13, 1890.
Improvements upon the same inventor's prior patents, Nos. 434,684 and 434,685, Aug. 19, 1890.
Claim 1 comprises :
A field-magnet and an armature having a sectional winding and commutators therefor and short circuiting brushes thereon adjustable with relation to the inducing poles of the field magnet to control the power and direction of rotation of the armature, a distributer receiving a continuous supply current and converting it into alternating currents.

Electric Transportation System, S. S. Wheeler and C. S. Bradley, 448,598. Filed July 29, 1889.
Claim 1 follows :
An electric transportation system comprising a movable vehicle or car carrying a magnetic mass, a guide way for said car and an inductor along the guide way, the mass and inductor being continuously in inductive relation and connection with a source of energy for propagating along the guide way a succession of polar waves, whereby a movement of translation will be imparted to the car by the successive waves.

Electric Railway, R. M. Hunter, 448,618. Filed Sept. 1, 1890.
Two tracks have their rails looped at one end and electrically connected together and with one pole of the generator; a separate suspended conductor is provided for each track and they are looped to correspond with the tracks and connected together and with the other pole of the generator.

Apparatus for Ventilating Railroad Cars, R. J. Wilson, 448,401. Filed Nov. 25, 1889.
The ventilating devices are operated by compressed air or fluid controlled by electro-magnetic apparatus.

Trolley Support for Electric Cars, B. F. Crow, 448,505. Filed July 12, 1890.
Designed to remove the weight from the central portion of the car roof. Employs a truss composed of a compression member and a tension member, their ends engaging.

Electric Railway, R. M. Hunter, 448,523. Filed March 18, 1886.
Line conductors are arranged in long sections with a generator for each section; controlling devices are actuated by the strength of current in one section for controlling the supply of current to the next section.

Telephones and Apparatus:—

Telephone, S. D. Field, 448,329. Filed May 25, 1889.
Claim 1 follows:
A telephone having its diaphragm supported between polar extensions of the two limbs of a magnet and magnetically connected at or near the rim, with an iron bridge connecting the poles of the magnet, each of the polar extensions being provided with a line coil wound to develop like polarities at the confronting ends.

Obituary.

CHARLES S. THOMPSON.

Charles S. Thompson, superintendent of the American District Telegraph Company in Brooklyn, died at his home in Brooklyn, on March 17, of apoplexy. His first attack of the disease followed closely on his witnessing the death of Lineman Feeks on Chambers street, in 1889, his nervous system sustaining a shock at the time from which he never recovered. Mr. Thompson was born at Chester, Orange county, N. Y., fifty years ago. He was in the telegraph business nearly all his life, having engaged in the construction of lines for the old United States Company in Virginia in 1865. He entered the service of the American District Telegraph Company March 12, 1872, and was appointed superintendent May 5, 1878. Two sons and two daughters survive him.

A NEW ARC LAMP.

A new arc lamp has been invented by a Pittsburgh patent attorney, which, if all the claims made for it can be sustained, says our Pittsburgh correspondent, will undoubtedly prove a good thing for the inventor. The claims set forth for the new lamp are that it will produce a stronger light than the ordinary arc lamp, that it is more simple in its construction and cheaper as to cost. But its greatest point of excellence is said to be its endurance. It is stated that the new lamp will burn continuously without requiring the renewal of carbons for 500 hours. This prolonged endurance is made possible through the peculiar construction of the carbons, which, instead of the ordinary pencil-shape, are made in the form of miniature emery wheels, four and eight inches in diameter, one wheel of each size being used for each lamp. They are placed at right angles, the larger over the smaller one, and by an automatic electrical arrangement inside the lamp they are kept in constant motion. A company is to be formed to bring the new lamp on the market.

CLEVELAND TRADE NOTES.

THE FORD & WASHBURN ELECTRIC CO.—This wide awake concern have had a phenomenally rapid growth in their business and are now very busy turning out their ventilated armature motor of all sizes and generators up to 500 light capacity, several of which large size they are building. Burn-outs are an unknown quantity with this armature, which is self ventilating and always cool, and the high efficiency, remarkable durability and fine workmanship of all their machines is very noticeable. They have issued a handsome catalogue, of which purchasers of motors and dynamos should not fail to secure a copy.

THE BUCKEYE ELECTRIC CO., of Cleveland, are largely increasing their capacity for the manufacture of their well-known incandescent lamps. They are now bringing out a perfected lamp of striking merit possessing many new and valuable features, amongst which the chief is an entirely new filament of great durability, very economical and of enormous tensile strength for so delicate a part as the filament of an incandescent lamp.

DAYTON, O.—The Dayton Globe Iron Works have furnished six 66 inch wheels to the Economy Light and Power Co., of Joliet, Ill.

LOCKPORT, N. Y.—Mr. David Maloney, formerly of Maloney & Palmer, has opened an office for electrical supplies and work on the ground floor of the Hodge Opera House. He will carry a full stock and will undertake all classes of work in his line.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"An advertisement should not be a mere jumble of big types confusing to the eye, but an irresistible statement of big opportunities convincing to the pocket."

ELECTRIC MERCHANDISE CO.

The above company, of 11 Adams street, Chicago, having become selling agents for the Tramway Rail Co., of Pittsburgh, Pa., it has issued announcements to that effect, and is now prepared to fill all orders for girder rails, tram rails, tee rails, chairs, tie plates, splice bars, frogs, switchings and other details of street railway equipment. The company has also distinguished itself by adopting a new monogram trade mark, which is intended to show how remarkable is the vivifying influence of Chicago on even the deadest of dead languages. Mr. W. R. Mason has a very successful style of dressing up "dry facts."

THE INSULITE SOCKET.

With regard to the "Insulite" lamp socket, which is now exciting so much attention, it should be stated that the inventor is Mr. Alfred Swan. Currency has been given to the report that it owes its paternity to Mr. T. G. Roebuck, the general sales agent of the company, but that gentleman has modestly hastened to disclaim the honor thus conferred upon him, finding glory enough in the large orders he has already begun to secure for it.

SILICON BRONZE TROLLEY WIRE.

This wire, manufactured by the Aluminum Brass and Bronze Co., of Bridgeport, Conn., combines strength, ductility, wearing qualities, and conductivity in a remarkable manner. The size usually used for trolley wire, No. 4, B. W. G., has a tensile strength of 80,000 pounds per square inch, and a ductility of over 30 twists in six inches. It has been found to outwear large wire of hard drawn copper, and on the street railway in Paducah, Ky., where it has been in use for the past eight months on curves of less than 50 ft. radius, it still shows no wear, and is in as good condition as when first put up.

On the Jamaica and Brooklyn Railroad, a large tree recently fell across one of these wires and held it to the earth under a tremendous strain. When the tree was cut away, the wire immediately sprung back into position, and has given no trouble since.

The general manager of the Erie Electric Motor Co. writes that he finds by actual measurement, that the wire in use on his road has not worn more than $\frac{1}{64}$ of an inch in nearly two years.

In addition to the roads above mentioned, silicon bronze wire is employed on the lines of the Sioux City Street Railway Co.; the Atlantic City Electric Railway; the Troy and Lansingburg; the Citizens' Rapid Transit Co., of Nashville, Tenn.; the Piqua, O., Street Railway Co.; the Lindell Railway Co., of St. Louis; the Laredo, Texas, Improvement Co.; the Binghampton, N.Y., Street Railway Co.; the Steubenville, O., Street Railway Co.; the North Avenue Railway Co., of Baltimore; the Keokuk, Iowa, Railway and Power Co.; the Salt Lake City R. R. Co.; the Chamberlain Investment Co., of Fort Worth, Texas; the West Bay City, Mich., Electric Street Railway Co.; the Erie Electric Motor Co.; the Marlborough, Mass., Street Railway Co.; the Eau Claire, Wis., Street Railway, Light and Power Co., and the Tramvia Del Chiantia Dei Colli, of Florence, Italy. All of these companies speak of the silicon bronze trolley wire in terms of the highest praise and are enthusiastic in their recommendation of it as the most serviceable wire for the purpose now in use.

WESTON ENGINES IN DEMAND.

The Weston Engine Co., of Painted Post, N. Y., reports business as brisk. They have sold recently of their Weston automatic engines two 75 h. p. and one 60 h. p. to J. R. Kemp, of Washington, D. C.; two 65 h. p. to Liberty Manufacturing Co., Savannah, Ga.; one 60 h. p. to S. Carson & Son, Riverton, Va.; two 15 h. p. and one 20 h. p. to The Steuben Electric Manufacturing Co., Hornellsville, N. Y.; two 15 h. p. to D. H. Darrin, for driving the electric plant of one of the finest buildings in Buffalo; one 20 h. p. to The Merrell Fabric Glove Co., Hornellsville, N. Y.; one 100 h. p. to the Weston Furnace Co., Manistique, Mich., and one 25 h. p. to Geo. Rightmire, Willawanna, Pa. They have also furnished horizontal tubular boilers for almost all of the above engines.

This company has lately secured as superintendent Mr. C. K.

Longenecker, who was formerly connected with the Harrisburg Foundry and Machine Department. He has adapted their engine especially to the electric lighting and railway business, and they are now making some bold bids for recognition in that line.

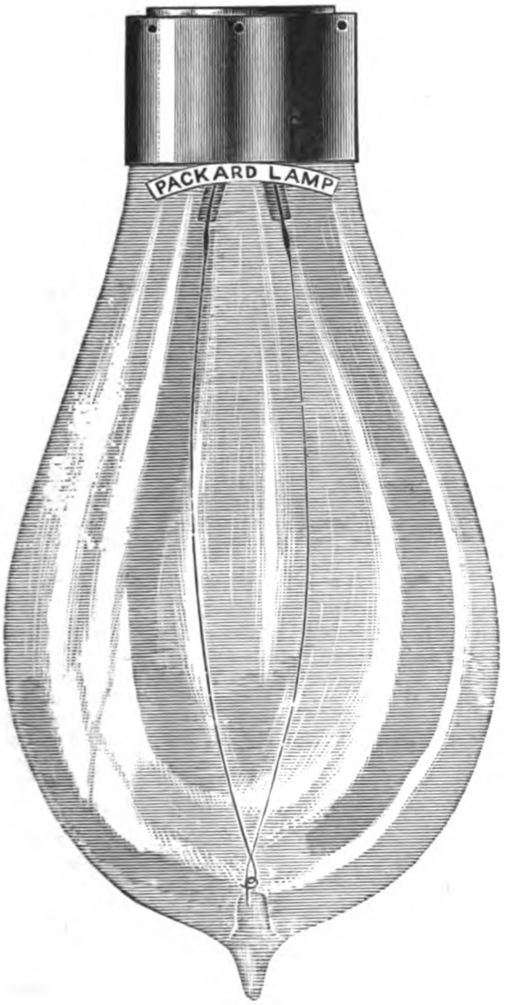
A USEFUL PAMPHLET ON BELTING.

C. W. Arny & Son, Philadelphia, have prepared and published a paper on the subject of transmission of power by belting, which will be of interest to all users of belting. The fact that C. W. Arny & Son have had unusual facilities for observation on this subject due to their long connection with belting interests as manufacturers and operators, makes the paper of especial value and it may be had from them on application.

THE NEW PACKARD INCANDESCENT LAMP.

We illustrate in the accompanying engraving the new Packard high-grade incandescent lamp, manufactured by the New York & Ohio Company, of Warren, Ohio. In producing this lamp, the aim of the manufacturers has been to make the best lamp possible regardless of cost, and this lamp is presented, not as a new or experimental one, but, as the perfection and result of seven years' experience in the commercial manufacture of lamps on a large scale.

In all their high-volt lamps from 90 volts and upwards, the carbon is supported at the tip by means of an inwardly projecting glass stem carrying a platinum hook. This prevents any drooping or vibration of the carbon, removing all danger of breakage from these causes and adding greatly to the symmetrical appearance of the lamp. The low volt lamps having a shorter carbon do not need this support, and it is therefore omitted.



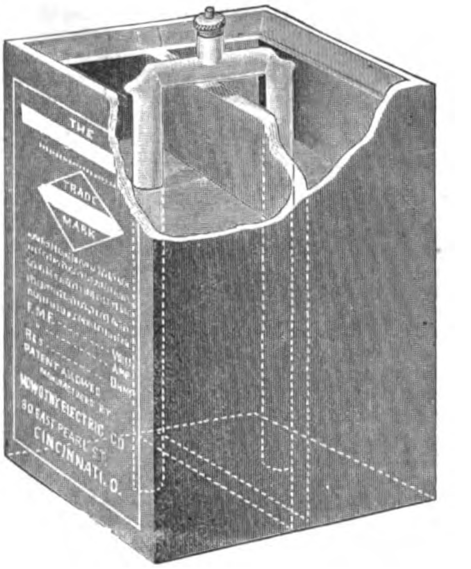
The Packard "High Grade" Incandescent Lamp.

Aside from the intrinsic value of the secret process of manufacture employed, the workmanship and materials are of the very best, and no molded glass or second-hand shells are used. Although in business but a short time, the company have an excellently equipped factory with a large force of experienced hands, and report business very good, while their lamps are everywhere giving great satisfaction.

THE MULTIPLE BATTERY.

The accompanying illustration shows the new "Multiple Battery" for telephones, electric bells, gas lighting, burglar alarms, annunciators, electric clocks, medical apparatus, and for all purposes where an open circuit battery can be used. It is manufactured by the Nowotny Electric Co., of Cincinnati, O., who claim for it high voltage and double the power of any other open circuit battery, together with less internal resistance.

The outer cell of the battery is composed entirely of carbon, with a carbon diaphragm dividing it into two compartments, making it equivalent to two cells coupled in quantity. The result is that a very large carbon surface is exposed to the action of the chemicals. The voltage is that of the very best cell, and the internal resistance is less than that of the average cell, with the quantity of two cells. The zincs consist of two pieces united at the top, one zinc entering each compartment, as shown. The terminals are electroplated with iridium, protecting the contacts from corrosion.



The "Multiple" Open Circuit Battery.

The battery contains an electrolyte of sal ammoniac diluted with water, and is ready for immediate use. The E. M. F. of this cell is 1.7 volt; current, 2 amperes; and resistance, .85 ohm.

THE "AMERICAN" ELECTRIC PASSENGER ELEVATOR.

Among the improvements introduced by Messrs. Behr Bros., the well-known piano makers, into their new building, No. 81 Fifth ave., this city, is an electric passenger elevator. This elevator, which was installed by the American Electric Elevator Co., of 15 Cortlandt street, New York, occupies a space of only 5 by 6 feet at the side of the elevator shaft in the cellar of the building, and operates with the greatest smoothness. In addition to the regular safety appliances, the elevator is equipped with a very simple arrangement by which the slightest slacking of the cable around the winding drum is followed by a cutting off of the current; this at once stops the elevator and thus avoids all danger from this source.

In this building the motor driving the elevator is in circuit with a separate meter and connected with the Edison street mains so that the exact consumption of current can be determined and charged for this service. In a recent letter Messrs. Behr Bros., after expressing their entire satisfaction with the operation of the motor, state that, as a matter of fact, it involved less expense for power than anticipated. This is strikingly brought out by the fact that the bill of the Edison Electric Illuminating Co., for current furnished to the motor between Jan. 31 and Feb. 28, 1891, amounted to only $5.62, the elevator running from 8 A. M. to 6 P. M.

CROCKER-WHEELER MOTOR CO.

The Crocker-Wheeler Electric Motor Company is soon to enlarge its establishment in West 14th street, this city, doubling the space it now occupies. This will enable it to have a large show room for exhibiting all sizes of Crocker-Wheeler perfected motors with their various applications, in operation, as well as a dust-proof department for the storage of finished motors and motor frames ready to be wound. The company find it necessary to carry a large number of motors unwound for filling special orders.

NEW DEPARTURE OF THE INTERIOR CONDUIT & INSULATION CO.

The extremely rapid growth and extension of the demand for tubes for interior wiring and for a great variety of details and fittings in connection therewith, has led the Interior Conduit & Insulation Co., of Broad street, New York, to take steps for the acquisition of such facilities as will enable it to engage in a general electrical manufacturing business. Inasmuch as its large new factory immediately adjoins that of the Bergmann Electric and Gas Fixture Co., it has become evident that it would be a good stroke of policy to absorb the latter concern and thus carry on the two businesses and the two factories, with corresponding economy in management and increase in profits. The Conduit Company has therefore secured an option on the Bergmann property, patents, machinery, etc., and steps are being actively taken to start the consolidated company in full operation. To effect the transfer, the Interior Conduit Co. is offering for sale $300,000 of its treasury stock, the subscription list to close April 4 at noon. The price is $75 per share. Of the $230,000 to be realized thus, $95,000 will be paid for the property acquired, and $135,000 will be used as working capital. The business which will be handled by the new concern is one of great scope, and the demand for its products is already very large. It need not be pointed out that the market for interior conduits is practically without limit, and that the company, as the pioneer in this line, is sure to reap a rich harvest from the conditions of the time which point indubitably to the universal use of ducts for interior work. The Interior Company has also some heavy work in immediate prospect in laying underground conduits for electric railways in leading cities. The Bergmann Co. has a progressive manufacturing business, and is engaged on work for the Western Union Co. and other electrical corporations, as well as making metal parts, etc., of the interior conduit system. Moreover, the consolidated company is to acquire the new patents of Mr. E. H. Johnson on electric railway appliances and motors, and will stand ready to develop any new apparatus of merit that may come along, whether designed by its own inventors and experts or brought to it for trial. The company will own over forty patents at its outset.

The officers of the present Interior Conduit and Insulation Co. are: E. H. Johnson, president; S. Bergmann, vice-president; F. A. Mason, secretary and treasurer; J. H. McClement, comptroller; E. T. Greenfield, electrician; E. W. Little, general manager, and Eaton & Lewis, general counsel. Messrs. H. Steers, C. E. Runk, S. Insull and F. J. Sprague are also directors.

THEY PREFER STORAGE BATTERY LIGHTING.

The Pennsylvania Company for Insurance of Lives and Granting Annuities, has ordered from the Electro Dynamic Company of Philadelphia, three series of 58 cells—total 174 cells—"15 L" type accumulators, with resistance cells, regulating switches, etc., complete, for lighting its building, No. 517 Chestnut street, Philadelphia.

The Pennsylvania company moved into their new building last summer, and for five months lighted their offices by means of the direct lighting system of the United States Company, changing then to the Edison system, taking the current from the mains in the street for three months, but finally concluded that the storage battery system, which they had had in operation in their old building, was superior to the direct system.

RECENT THOMSON-HOUSTON SALES.

The Thomson-Houston Electric Co. reports the recent sale of the following apparatus: *Arc plants:* Ashland, O., 50; Lowell, Mich., 50; Mansfield, Pa., 25; City of Chicago, Ill., 50; Elyria, O., 70; Louisville, Ky., 50; So. Chicago, Ill., 150; Greenville, Mich., 60; Lincoln, Neb., 150; Newport, Ark., 50; Joliet, Ill., 150; Arkadelphia, Kan., 30; Medina, N. Y., 50; Olathe, Kan., 50; Parsons, Kan., 35; Hyde Park, Ill, 50; Clinton, Mo., 50; Shelbyville, Mo., 50; Oshkosh, Wis., 50; Harrison, O., 35; Osage, Ia., 18; Farmville, Va., 30.

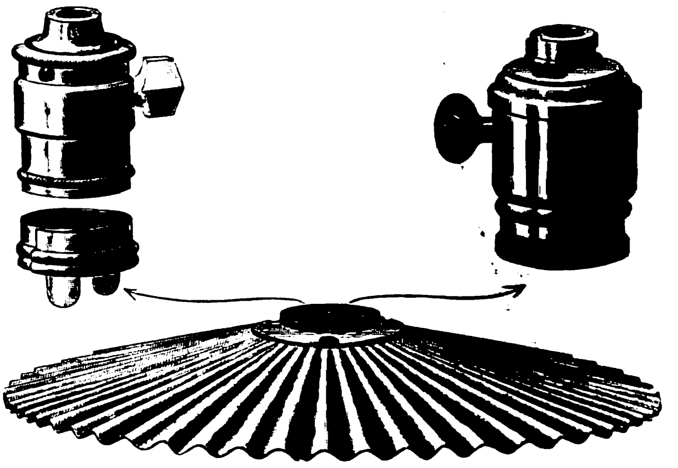
Incandescent plants: Quincy, Ill., 1,300; Monroe, Wis., 1,300; Moosie, Pa., 300; Morristown, Tenn., 650; White River Junction, Vt., 650; Arkadelphia, Kan., 650; Olathe, Kan., 650; Pella, Ia., 650; Waterville, Conn., 1,300; Babylon, L. I., 650; Clinton, Mo., 500; Boston, Mass., 650; Chelsea, Mass., 1,300; Harrison, O., 650; Huntington, Ind., 650; Port Huron, Mich., 1,300; Tuscola, Ill., 500; Worcester, Mass., 1,950; Pawpaw, Mich., 300; Edinburg, Ill., 300; Bennington, Vt., 1,300; Omaha, Neb., 1,300; New Albany, N. Y. 650; Greenville, Mich., 650; Virginia City, Nev., 650; Farmville, Va., 300; Mt. Vernon, N. Y., 1,300; West Superior, Wis., 1,300; Charleston, W. Va., 1,300.

Isolated plants, arc: Schlitz Brewing Co., Chicago, Ill., 6; Alger, Smith & Co., Black River, Mich., 30; J. P. Craig, Memphis, Mo., 30; Glenwood Co., Yonkers, N. Y., 9; Sanderson & Sons, New York, N. Y., 30; Central Iron Works, Harrisburg, Pa., 50; Bradner, Smith & Co., Chicago, Ill., 20; Woodcock & Loring, Chicago, Ill., 12; D. B. Fiske & Co., Chicago, Ill., 35.

Isolated plants, incandescent: Warden Apartment House, Philadelphia, Pa., 1,600; Tuscaroras Advertising Co., Coshockton, O., 100; Backus Wire Nail Co., Cleveland, O., 400; Read House, Chattanooga, Tenn., 600; Hotel Oglethorpe, Brunswick, Ga., 150; Deloach Mill Manufacturing Co., Atlanta, Ga., 100; Nat. Distilling Co., Milwaukee, Wis., 100; St, Louis Railway Co., St. Louis, Mo., 200; A. Zeese, Chicago, Ill., 100; Lane Bros., Newark, O. 150; C. E. Harwood, Lynn, Mass., 150; G. A. Robertson & Co., Hinsdale, N. H., 50; Brooks Bank Note and Lith. Co., Boston, Mass., 100; Orr & Strettle, Piqua, O., 600; Piedmont Bath and Power Co., Oakland, Cal., 500; Fitchburg, Mass., Mfg. Co., 200; Calumet Distilling Co., New Chicago, Ill., 450; H. C. F. Koch, New York, N. Y., 1,200: New York Jockey Club, New York, N. Y., 800; Liss & Rickerman, Chicago. Ill., 100; D. B. Fiske & Co., Chicago, Ill., 250; Walter Aiken, Franklin Falls, N. Y., 100; Clark's Hotel, Boston, Mass., 150; Monmouth Park Hotel, Little Silver Station, N. Y., 800; Wm. Ruehl Brewing Co., Chicago, Ill., 200; E. Richards & Son, Sandy Hill, N. Y., 100; Jordan & Stewart, Oldtown, Me., 50; Newmarket, N. H., Mfg. Co., 400; E. P. Parksons & Co., Tilton, N. H., 200; American Scotch Iron Co., Syracuse, N. Y., 50; E. Frank Lewis, Lawrence, Mass., 100; American Tin & Lead Co., Canon City, Col., 200; Fairchild Paper Co., E. Pepperell, Mass., 200; Gouverneur, N. Y., Wood Pulp Mfg. Co. 50; Lockport, N. Y., Pulp Co., 200; No. New York Marble Co., Gouverneur, N. Y., 50; Allen Bros. & Co., Sandy Hill, N. Y., 400; Walter M. Lowney, Boston, Mass., 200: Clarendon Hotel, Brooklyn, N. Y., 400.

AN IMPROVED INCANDESCENT REFLECTOR.

THE accompanying illustration represents a reflector just brought out by the Electrical Supply Co., of Chicago. It is of tin, bright inside and green without, after the usual fashion, its novelty lying in the method of its application to the lamp. As will be seen, there are no screws, no springs and no clamps. It is attached directly to the lamp socket without the use of a shade holder. Instead of all these, a small clip is used for fastening to the sockets, which have no special holding arrangement. Taken altogether, the new reflector is extremely simple and serviceable.



IMPROVED INCANDESCENT REFLECTOR.

THE CRESCENT INSULATED WIRE & CABLE CO.

The above company have entered the field with the determination of securing a large share of the insulated wire business. Their wires are all covered in such a way as to be entirely seamless on either side. "We not only use," they say, "the highest grade of Lake Superior copper and of 'Old Para' rubber, but our manner of treating the caoutchouc in our compounds is such as to secure the highest degree of insulation resistance." The factory and main offices are at Trenton, N. J. Mr. C. Edward Murray is the president of the company, Mr. Richard R. Whitehead, vice-president and treasurer, and Mr. Harry T. Solliday, secretary, while Mr. Thomas S. Reed is the superintendent and electrician. The company have prepared and printed a price list of their various styles of wire.

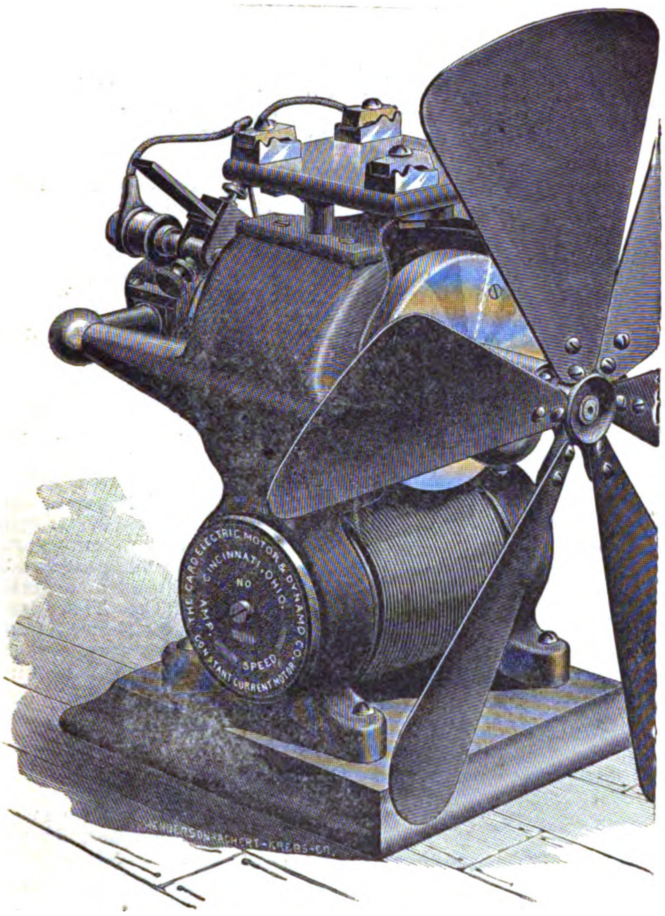
OMAHA, NEB.

An electrical engineering company has been formed by B. D. Kennedy, R. B. Howell, J. P. Allen and H. E. Chubbeck with a capital stock of $25,000. The company will construct, operate and repair electric circuits and do other work of an electrical nature

THE CARD FAN MOTOR.

It is appropriate at this time, when it is beginning to become evident that summer will soon be upon us, to bring to the notice of our readers anything that tends to lessen the burden of life during that trying season. In this connection we may mention a new fan motor, having several points of interest and merit, that has recently been brought out by the Card Electric Motor and Dynamo Co., of Cincinnati. It is very compact, and of exceedingly simple construction. The commutator is of large size, which makes it exceedingly durable, and the machine will give the full rated power, and even exceed it, if necessary, without burning out. This is an important point, as there is a general tendency to overload small motors.

As will be seen in the accompanying illustration, a single field coil is used, and the motor is fitted with self-oiling bearings requiring a minimum of attention. It is built in two sizes, ⅛ and ¼ h. p., and as carefully constructed as a large machine. It is efficient in operation, durable, and thoroughly reliable.



CARD FAN MOTOR.

NEW ISOLATED PLANT OF THE PACIFIC ELECTRICAL STORAGE CO.

In order to meet the demand for small incandescent light plants, the Pacific Electrical Storage Co., of San Francisco, Cal., has designed an installation which renders the consumer independent of outside institutions, and gives light comparing favorably with gas as to cost of maintenance. It consists of a 1 h. p. gas engine, 11 cells of "15-M" type accumulators, a switch-board, a shunt wound dynamo having a normal output of 16 amperes and 30 volts, and 20 16-candle power lamps and key-sockets.

No difficulty is experienced in setting the engine and dynamo, the latter of which requires a floor space of about 24 by 12 inches, and full instructions are furnished for wiring. The battery is entirely automatic, and 99 per cent. of the lights may be turned off at once without in the least affecting the other lamps or the working load of the dynamo, and hence but little attention is required.

By running the dynamo five hours a day, enough current can be generated to supply 30 lamp-hours per day. If for two hours in the evening it should be required to run the dynamo to supply an additional 8 lamps, this would make a daily consumption of 46 lamp hours, and a run of 7 hours for the engine, which burns not more than 30 cubic feet of gas per h. p hour. Gasoline instead of gas may be used as fuel if desired.

The company also furnishes plants of larger capacity when required.

By the placing of storage batteries as an adjunct to the incandescent plant, the lighting capacity can be doubled; or, if it is desired to install an incandescent plant of a given number of lights, it is only necessary to install a dynamo and engine that will be able to carry half the total number of lights during the hours of maximum load, the storage battery furnishing the current for the remaining half, and receiving its charge during the hours of light load. This system, commonly known as the "half and half" system, reduces the first cost of the steam and dynamo plant by nearly one-half, a very important item.

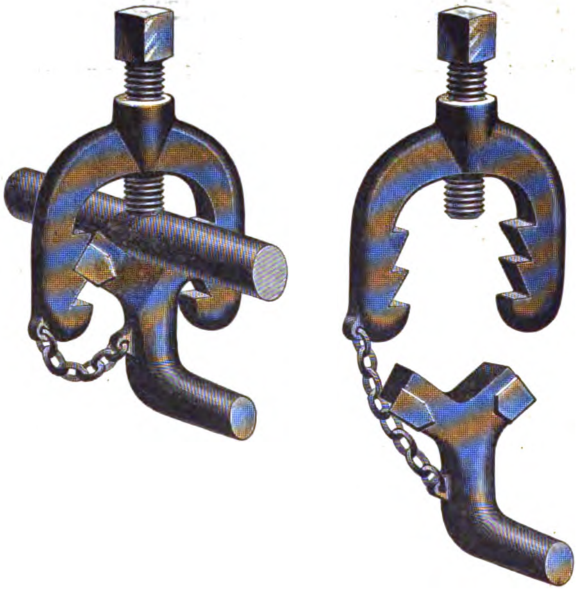
THE SAMSON CORDAGE WORKS.

The Samson Cordage Works, of Boston, have been sending to electric light companies and supply houses, sample cards showing their solid braided cordage for suspending arc lights, street car trolley cord, and for covering the magnets of dynamos. This cord has been used for such purposes by a few for a number of years, and now that the manufacturers have taken steps to make the goods generally known they find a very gratifying increase in trade.

A NOVEL LATHE DOG.

THERE has always been more or less annoyance, inconvenience and loss of time in machine shops, from the fact that lathe dogs must be adjusted to the work before centering it in the lathe.

The accompanying illustrations show a dog manufactured by The Indispensable Lathe Dog Co., of 1209 Buttonwood St., Philadelphia, which overcomes this objection. It can be attached to work after the work is centered in the lathe, and can be used as well between collars as upon plain or straight work. A large dog can be used on a light mandrel where the work is large in circumference. It can also be used for locking work on the mandrel to prevent slipping. These dogs are drop forged from bar steel, and fitted with steel set screws. They are made in four sizes, the smallest taking from ¼ to 1 inch, and the largest, from 1 to 3¼ inches.



THE "INDISPENSABLE" LATHE DOG.

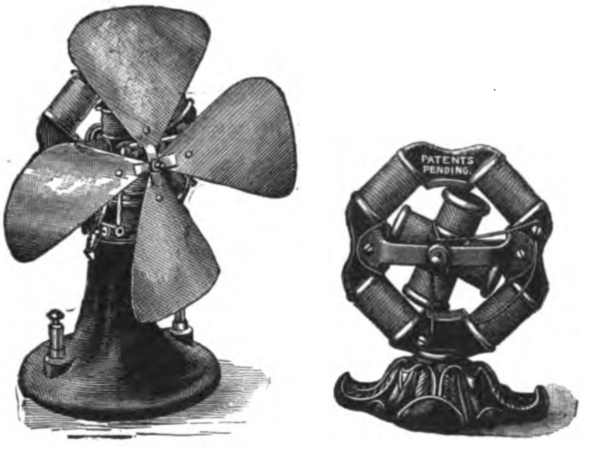
THE CENTRAL ELECTRIC COMPANY are making a special drive on hard rubber goods, offering the celebrated products of The Butler Hard Rubber Company, New York, at prices lower than ever, and making prompt shipments, which is telling with the trade and consumers. They are introducing a compound that takes a good finish, and is specially recommended for its insulating qualities. As the sole Western agent for the Paiste Edison Key Socket, the Central Electric Company have already had numerous large orders for this latest improved socket, which is virtually a 5 ampere Paiste switch mounted in a handsomely finished shell.

PACIFIC TELEPHONE ATTACHMENT & RECORD CO.

The above company, of 206 California street, San Francisco, are introducing a simple device which can be readily attached to any telephone, whereby the handle of the magneto is completely covered by a case or door. Into a slot in this door one can drop a coin, whereupon the door will open; and until the door is opened the telephone can not be used. The coin drops into a receptacle to which the owner of the attachment alone has a key and lock. The attachment is so regulated that the door will open with either a nickel, dime or quarter, as may be desired. As a cure for dead-head telephoning the device seems to possess many notable recommendations.

E. S. RITCHIE & SONS' MOTORS.

We illustrate herewith two small motors, the design of Mr. W. B. Luce, which have recently been brought out by E. S. Ritchie & Co., of Brookline, Mass. They are of various sizes, from that which will run a toy or a small fan up to those capable of driving a sewing machine, dental and other small lathe, and the like. They are very handy for lecture illustrations and minor experiments requiring power. The firm will also supply castings, finished or unfinished, for small motors, so that the student or beginner may do a little experimenting in motor design and construction on his own behalf. It may be mentioned that the house supply hand-dynamo machines, which will furnish a current capable of good work.



Ritchie & Sons' Motors.

CINCINNATI TRADE NOTES.

The Electric Supply and Contracting Co., Nevada Building, Cincinnati, O., are doing a large business in various kinds of electrical apparatus and supplies. They are agents for the well-known C. & C. motors, a large number of which they are installing. They also pay attention to repair work, rewinding armatures, etc., and wiring of buildings for arc or incandescent lighting, and electrical and mechanical engineering work of all kinds. Mr. F. E. Perry, widely known in electrical circles from his long connection with the Edison Co., is the manager of the company, and associated with him are Mr. Geo. C. Kuntz and Mr. S. I. Crain.

The Triumph Engine Co., Cincinnati, are kept busy filling the demand for their compound engines, which are giving universal satisfaction wherever installed. Their engines are noted for their economy and simplicity, and are remarkably durable and reliable.

The Boughen Engineering Co., 179 Race street, Cincinnati, engineers and contractors, have several large jobs in power plants for electrical work on hand, and are figuring on numerous others. They make a specialty of this class of work and have installed some very fine plants, which are giving excellent satisfaction. In addition to electrical work they have several large complete steam plants under way.

The Lane & Bodley Co., Cincinnati, O., the well-known builders of improved Corliss engines are turning out a large number of these engines of various sizes and large quantities of other machinery for power plants of all kinds. They are furnishing all the engines for the Hunt street power house for the electric street railway plant. Steam is supplied from a battery of boilers of 1,000 h. p., with Murphy furnaces, and 14 miles of road with 20 motor cars and 20 trailers are in operation. The plant will shortly be increased. Mr. Philip King has charge of the road and Messrs. J. E. Ginter and Jas. Taylor are the engineers and look after the running of the plant.

The Colerain Avenue Electric Railway Plant.—This street railway plant is one of the best equipped in the country. The Thomson-Houston system is used. It is a double trolley wire road, thereby obviating any trouble to telephone wires by induction currents. The present plant comprises eight 80,000 watt Thomson-Houston generators driven by one Hamilton-Corliss engine of 400 h. p. and 2 Ball engines of 250 h. p. each. A Buckeye engine of 30 h. p. is used for running a separate generator for lighting purposes.

Thomas J. Creaghead, consulting and constructing electrical engineer, with offices in the Mitchell Building, Cincinnati, O., is doing a very good business in territory around Cincinnati. He is handling some of the latest specialties in the electrical supply line and is prepared to put in any kind of an electric plant, from a fan motor to an electric railway.

NEW YORK TRADE NOTES.

The Shaver Corporation, of 207 Broadway, this city, report business as very brisk for their acoustic telephones. They have a complete telephone outfit, and its adoption in several prominent cities of the country has served to demonstrate its efficiency in every way.

Page Belting Co.—Since this company have opened their New York store at 16 Dey street, with Mr. Geo. A. Pierce as manager, business has been coming along very nicely. The "Acme" link leather belt manufactured by this firm runs without slip, and with minimum strain upon the journals and bearings. For those who have tried linked belts and do not feel satisfied with the manner in which they have worked, a visit to Mr. Pierce will perhaps prove of interest and value. They also make all kind of belts for electric light purposes.

Mr. M. J. Sullivan, has been transferred from the legal department of the Edison Electric Light Co., to the intelligence department of the Edison General Electric Co., with headquarters at the Edison building, 44 Broad street.

Asa W. Hall, once connected with the Ball Electric Light Co., of this city, is now, and has been for the last eighteen months, electrician for the National and Providence Worsted Mills, Providence, R. I. This is one of the largest isolated manufacturing plants in that State, and is made up of 1,600 incandescent and 350 arc lights. The incandescents are of the Edison and Mather systems, the arc lighting being done by the Ball Co. There are 14 arc machines in use. A recent visit to this plant showed that a great deal of pains was being taken with the apparatus, and Mr. Hall is to be congratulated upon the success of the plant under his charge.

Innis & Co., of 120 William street, this city, are importers of a superior grade of sal ammoniac for battery purposes, and on orders of large quantities can quote some good prices.

C. S. Van Nuis, of 74 Cortlandt street, this city, is having quite a run with the "Ajax" switches. He also designs slate switch-boards on which he uses some of his patented novelties, the result being a switch-board it would take hard work to excel.

Edward Cliff, late chief lineman for the Richmond Light, Heat & Power Co., Staten Island, has invented and patented the "Cliff Mast-Arm" which is used by that company. It is being placed on the market for general adoption by W. H. Kinlock, of New Brighton, S. I.

The Palermo Mica Co., of 27 Peck Slip, this city, are dealers in mica for all purposes. The amount of mica which this company furnishes for the electrical industry is something enormous. Mr. Melville Seabury is sales manager.

Belding Bros., of 455 and 457 Broadway, this city, silk manufacturers, are making the finest silk for electrical purposes. They have large mills both in Rockville, Ct., and Northampton, Mass. Mr. C. W. Darling presides over the interests of the New York store.

The Crowdus Chemical Electric Co.—There are doubtless a number of our readers who will welcome in the electrical field, as wholesale dealers in supplies, the Crowdus Chemical Electric Company, of Memphis, Tenn. This company has secured a handsome five-story building, having floor space of 25 x 150 feet, situated on the principal business street.

They have equipped, the top floors with machinery for the manufacture of their Crowdus battery, and specialties, and will devote the remaining floors to supplies, having already secured the agency for several leading staples. They will carry a stock of electric fixtures and have for this a room wired with fifty outlets, in which are displayed the many beautiful effects of handsome electroliers and bulbs.

Their building is lighted with arc and incandescent lamps, the current for them being taken from their remarkable Crowdus batteries. Mr. Crowdus announces that they have received, without asking, as many orders for batteries as they can fill until their new factory is entirely equipped.

THE
Electrical Engineer.

VOL. XI. APRIL 1, 1891. No. 152.

RULES AND FORMULÆ FOR INCANDESCENT LAMP WIRING.—I.

BY

Carl Hering

IN the ideal system of wiring for incandescent lamps (or motors) in multiple arc, there are two requirements, assuming that the potential is kept constant at the source: *First*, that each lamp should have the same potential at its socket, as all the other lamps, when all are burning at once; *secondly*, that this potential should remain constant at each lamp, when the other lamps are turned off. In some cases, as for factories, street lights, store lights, etc., only the first requirement need be complied with; in other cases, as in dwellings, theatres, etc., both conditions must be provided for. The second condition is the one most difficult to provide for, and it necessarily includes the first. A number of systems of running the leads will comply with the first condition, but to meet the second condition there is only one ideal system.

In general, it would be quite impracticable to comply strictly with either of these conditions, and therefore a slight margin of variation at the different lamps is usually allowed; the amount of such allowable variation, being necessarily different for different conditions, must be chosen by the judgment of the engineer. This variation is due to the different losses in potential in the leads to the different lamps. This variation is therefore not identical with the loss in the leads, but it is the differences between these losses when the losses are not precisely the same to all lamps.

The amount of wire used increases very rapidly as the allowable loss is diminished; for a 1 per cent. loss, for instance, the amount of wire by weight is double what it would be for a 2 per cent. loss. On the other hand, if the lamps must be capable of being turned off one by one, the life of the lamps in the general systems diminishes rapidly as this allowable loss is increased, because the unavoidable differences between the losses to different lamps, that is, the variation, increases. It is therefore a choice between two evils. As the conditions are quite different in the case when the lamps may be turned off one by one, from that in which they always burn together, the two cases must be considered separately and should not be confounded with each other; the former, of course, includes the latter, and is therefore merely an additional condition to the latter.

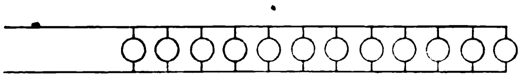


FIG. 1.

The case in which all the lamps are either burning, or turned off together, is by far the simpler of the two. In the simple case shown in Fig. 1, the difference between the potential at the nearest lamp and that at the farthest, is merely the amount lost in the length of wire between the two lamps, and it is entirely independent of the amount lost between the dynamo (or centre of distribution) and the first lamp; this latter loss, may, therefore, be made as great as desired, as far as the lamps are concerned. In this case, therefore, the loss from the dynamo to the first lamp may be made anything that is desired, but the wire between the first and last lamp must be so large that the loss on that portion does not exceed the allowable variation for the lamps, say, about 1 per cent or at most, 2 per cent. If this portion of the circuit is so long that it would require a very large wire, then the lamps are often divided into two or more groups, as shown in Fig. 2, each group being supplied or fed by a separate set of leads; these two separate sets of leads must then be calculated for the same loss as before between the dynamo and the lamps, thus requiring the longer ones to be much thicker than the shorter ones, as shown. The choice between the dispositions shown in Figs. 1 and 2, depends entirely on whether the wire between the first and the last lamp must be so thick, owing to the allowable difference between the lamps, that it would be cheaper to divide the leads to dynamo into two parts; this can be determined only by calculating both cases. In Fig. 1 it might, under special circumstances, be quite rational to connect the lamps by a much thicker wire than that leading to the dynamo, even though the latter carries a greater current. The disposition shown in Fig. 2, of running separate sets of leads to different groups of lamps, applies equally well to groups of lamps in different directions from the centre of distribution, and in this sense it is one of the most frequent and best systems of distribution.

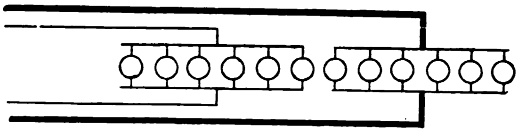

FIG. 2.

Another system, but applicable only in special cases, is that shown in Fig. 3, in which the two leads from the dynamo divide, one going in one direction around a rectangle, and the other going in the reverse direction. No matter what the loss or the size of the wire, all the lamps between this pair of leads, will have the same potential, provided the positive and negative leads are both of the same size, and provided all the lamps are turned on and off together; if the lamps are turned off one by one, the potential will no longer be constant.

To recapitulate, it will be seen, that when the lamps of a group are all turned on or off together and not individually, the distribution is simple, requiring only, that the *difference* between the potential at the nearest and the farthest lamp on the same leads shall not exceed the allowable variation of 1, 2 or even 3 per cent. (in which case the lamps are entirely independent of the loss between them and the dynamo or centre of distribution), and that if there are a number of such groups connected to the same dynamo or centre, the loss from dynamo to lamp must be the same for each group. In the latter case the groups will be entirely independent of each other, and may be turned off or on as individual groups, provided their leads do not join those of any other group on their way to the dynamo. In other words, groups having independent connections to the dynamo, are independent of each other, and may be turned off or on as groups. It is assumed, of course, that the dynamo is self-regulating.

Taking up the other case, in which the individual lamps are to be turned off and on, the problem is quite a different one. Referring again to Fig. 1, the loss of potential from each lamp to the dynamo or source depends on the total current in the common leads and on the resistance of these leads; these losses therefore remain constant only as long as the total current is constant; if one lamp is turned off, the total current becomes less and therefore the loss to each remaining lamp becomes less, and *vice versa.* Finally, if all but one of the many lamps are turned off, the loss in the leads will be very small, and, therefore, the potential at the last remaining lamp will be increased accordingly. Each individual lamp is therefore dependent not only on the others, but also on the total loss of potential between it and the dynamo. It is in the latter feature that this case differs entirely from the first case described above, in which they are all turned off or on together. For independent lights the loss between them and the dynamo must therefore be made as small as practicable, as it affects the steadiness and life of the lamps. For this reason it requires, in general, relatively thicker wire for independent lamps than for groups, provided the distance to the dynamo is sufficiently great to make a difference.

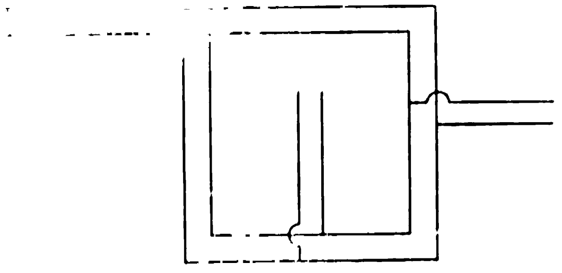

FIG. 3.

Suppose, in Fig. 1, there are 100 lamps and the loss from the dynamo to the first lamp is four volts when all are burning; then if all but one are turned off, the voltage of that one will be about four volts in excess of what it should be. In order to save the lamps from part of this strain, the voltage of the dynamo may be so chosen that when all are burning they will be two volts below the normal, and when only one is burning it will be two volts above, the difference remaining, as before, four volts. If, as in a dwelling, the full number of lights burning is the exception, and a few lights, the rule, then the potential at the dynamos may be chosen so that it is the proper amount at the lamps when the average number is turned on.

As the potential at the lamp depends on the total current in the leads, it follows that the ideally perfect system of independent lamps is, to have a separate pair of leads for each lamp back to the dynamo (or centre of distribution). Each pair of leads is then calculated so as to have the required loss for its lamp. Such an ideal system is, however, not practicable as a rule, but the general rule may be laid down, that the nearer a system approaches to this ideal, the better it is. For instance, comparing Figs. 1 and 2, in each of which there are twelve lamps, the second approaches more nearly to the perfect system, and the lamps in Fig. 2 are subjected to only *half* as great a variation in potential as those in Fig. 1, when all but one are turned off. It follows from this rule that the distribution is better, the more a circuit is branched, the nearer such branch connections are to the dynamo, and the larger the number of independent leads to the dynamo. Such distribution is better, not only because the lamps are subjected to less variation of potential, but for the same allowable variation of, say, 2 per cent. at the lamp, the total loss from the dynamo to the lamps may be chosen much greater than in other systems thereby saving wire, for it is evident that in the ideal system the loss from the dynamo to the lamps may be made anything desired, without making the lamps dependent on each other. Their dependence on each other varies with, and is proportional to, the number of lamps on one wire, and the distance from the dynamo to the junction of their individual wires.

It is sometimes thought that the ideal system may be carried out by calculating the leads to each lamp or group of lamps separately and then bunching all the wires running parallel, into one common wire having a cross section equal to the sum of all the smaller wires combined. But this is an error, and may result in a worse distribution than if it had been calculated on the usual plan. As soon as two wires are metallically connected, they become one and the same wire from there to the dynamo.

To recapitulate: When the lamps are to be cut off independently, they are dependent on each other and on the loss of potential between them and the dynamo, *in so far as they are connected to common leads.* The leads should therefore be split up as much as practicable and the total loss should be divided so as to have the greater part in the small individual branch wires, and the smaller part in the larger main wires.

ON THE DESIGN OF ALTERNATING CURRENT MOTORS.

BY

A. H. Weston.

A SERIES of experiments and investigations, conducted for some time past by myself, leads me to believe that the alternating current is as applicable to the purposes of power as the constant current, but that certain definite conditions must be observed in the design of alternating current motors which do not come into consideration at all in a constant current motor. It is true, I have, so far, experimented only with small motors, but I believe that large self-regulating motors can be constructed according to the same principles, to operate successfully.

In dealing with the alternating current, one of the most important things to be considered is the self-induction which the current tends to set up, producing an E. M. F. contrary and inimical to its own E. M. F. This self-induction, which is the attribute of the dynamic nature of the alternating current, always acts to destroy or neutralize the current which sets it up. In exactly the same manner does the expansion of steam, or other vapor, whose force of expansion is due to heat, and by means of which expansion it does its work, consume or neutralize the heat which produces the force.

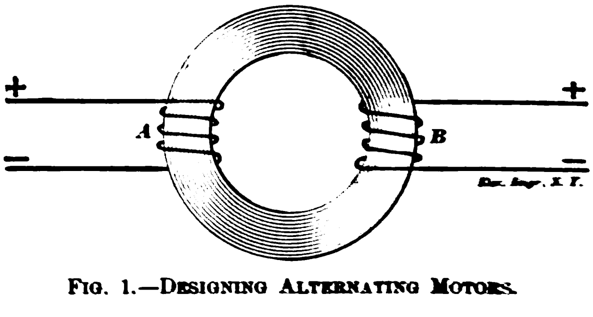

FIG. 1.—DESIGNING ALTERNATING MOTORS.

Now in making an alternating current motor it is necessary to dispose the windings on the magnetic circuit so that the value of the self-induction will vary as nearly as possible inversely as the work done by the motor. I believe that this condition can be approximated, if not exactly attained, by having due regard to the magnetizing and mutual inductive effects of the windings on the armature and field.

Let us consider the behavior of two similar coils of equal magnetizing effect, wound upon a simple magnetic circuit. Fig. 1 shows such an arrangement. In all cases we will assume that the magnetic circuit is thoroughly laminated in the direction of the lines of force, as that is, of course, always necessary.

If an alternating current is caused to flow through the coil A having at any instant the polarity indicated, there will appear in the coil B, if the circuit of the same is completed, a current of opposite polarity, as indicated, which will vary with the resistance of the circuit. If the coil B remains open so that the resistance through its circuit is infinite, the self-induction produced by the current in the coil A will react against the said current, and, if the inductive properties of the iron were perfect, would cause a counter E. M. F. equal to the original E. M. F. producing the current and check it altogether. This is, in general, the action of the converter.

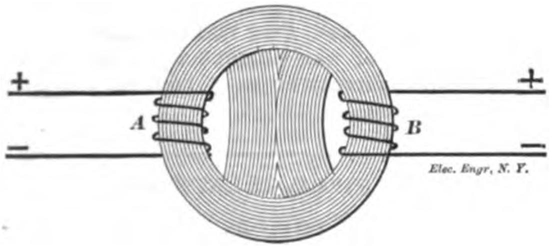

FIG. 2.—DESIGNING ALTERNATING MOTORS.

If we impress upon the coil B an E. M. F. similar to the E. M. F. producing the current in A but reversed in direction to that shown in Fig. 1, we will experience the same result as in our last experiment, only *more so*, so to speak. If, on the other hand, we cause the same alternating current or similar currents to pass through each coil in the direction indicated in Fig. 1, it will not only be found that the self-induction will be entirely eliminated, but if the E. M. F. is maintained the same at the terminals of each coil, the current flowing through each will be proportional to the sum of the two E. M. F's.

Let us now divide the magnetic circuit of the iron ring by establishing a magnetic path across the ring, as shown in Fig. 2, and cause the current to pass through the coils in the direction shown. What will be the result? We will now find the self-induction present in full force, as in the case of the transformer with an infinite resistance in the secondary circuit. Both coils now co-operate to project the lines of force across the centre path in the same direction. This is the condition which would exist if we were to consider the ring as a motor field and place an inert armature within the ring.

If we now consider the nature of an armature apart from its field, such as the ordinary form of Siemens drum armature or Gramme ring, we will readily see that, supplied with current from two brushes set at diametrically opposite points of a commutator, it can be considered for the purposes of this discussion as similar to the system shown in Fig. 1, but better shown in Fig. 3. That is to say, apart from the field, in a non magnetic medium, such as air, an alternating current will encounter no impedance in passing through the windings, save that due to one-quarter of the whole ohmic resistance of the coils. If, however, we place it in an inert field, as shown in Fig. 4, we provide a magnetic path from one side of the system to the other, producing the same condition in the armature as we have in the field in Fig. 2, only that the path is external, instead of internal. In this case the magnetizing effect of the armature coils tends to project the lines of force across this external path in the same direction, and this produces self-induction in the armature coil which checks the current, as in the last case considered, of the field.

Fig. 4, it will be seen, is perfectly analagous to Fig. 2, excepting that in Fig. 4 we have the means of causing magnetic energy in the centre path, *per se* inert in Fig. 2. We will now cause an alternating current to pass through the field coils in the direction shown in Fig. 4 and a like current to pass through the armature coils so that the magnetic forces of all the coils tend to project the lines of force through the armature path in the same direction. The self-induction will now attain its maximum value in all of the coils and the system, so arranged, will be practically opaque to the passage of current, as in the third case considered in connection with Fig. 1. In this condition the armature will have no tendency to revolve, as the magnetic current defined by the magnetizing forces of the field and armature coils will be the shortest circuit possible through the system and the forces between the field and armature will be in equilibrium. The points of contact of the brushes with the commutator will now coincide with the polar line C D of the field and armature. This, theoretically, will be the condition under which a perfect motor will work with no load. By this, I do not mean that the brushes would necessarily be at this point. They might, or might not, be.

The last to be considered is the case wherein the magnetizing force of the armature is reversed, which can be accomplished by swinging the brushes, as last connected, through an arc of 180°, where they will again coincide with the polar line of the system. Here we have the magnetizing forces of the field and armature coils tending to project lines of force around the circuit in opposite directions and we will have in all of the coils the same condition as we had in the armature coils apart from a field, or in the field coils apart from an armature, in the last case considered in connection with Fig. 1. In this position an excessive current will pass through the coils and the armature and field will be in a condition of neutral instability. The slightest displacement of the armature in either direction will give it tendency to move in that direction. In popular language, it would move by repulsion.

It will now be readily understood that there will be a position of the brushes between these extreme positions where the resultant opposing magnetic force of the armature will create a "reluctance" in the armature portion of the magnetic circuit, less than the reluctance which would result from the removal of the armature altogether, leaving only an air space, and greater than the reluctance of an inert magnetic path, such that the self-induction of the coil would just be eliminated.

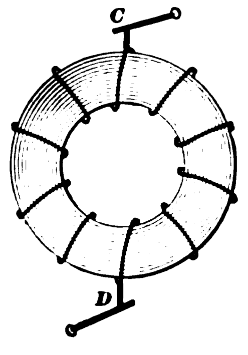

FIG 3.—DESIGNING ALTERNATING MOTORS.

This is, theoretically speaking, the desired condition, although practical considerations of regulation might dictate some departure from this. By making the magnetic force of the armature coils of sufficient magnitude, this condition can be attained at the point where the brushes will give the most effective torque to the armature. With the armature clamped in this position the current will experience only the ohmic resistance of the coils and the motor will take its maximum current, which will produce a powerful directive tendency in the armature to revolve.

The acceleration of the armature in its attempt to reestablish equilibrium will cause a diminution of the opposing force exerted by the armature coils, which causes a rise in the self-induction and counter E. M. F. in the coils, and by a proper utilization of this property the motor will be self-regulating for speed under varying conditions.

Now a word about the relative magnetizing forces of the field and armature coils. We know it is the practice in constant current motors to make the magnetizing force of the field greatly preponderate over that of the armature and the armature core takes its resultant magnetic complexion from the field. It can readily be seen that this will not do at all for an alternating current motor, as the armature must be able to outweigh the field in magnetizing power. As a rough approximation, we will say that the effective magnetizing force of the armature coil must be equal to that of the field coils. As the effective magnetizing force of the armature coils is not the whole magnetizing force represented by the ampere turns of its coils we must make due allowance therefor.

The relation which the effective magnetizing force bears to the magnetizing force is as follows :—

Let M = the total magnetizing force of the armature turns, and m, the effective force. Then $\frac{m}{M} = E$; E being the average value of sin β between 0° and 90°.

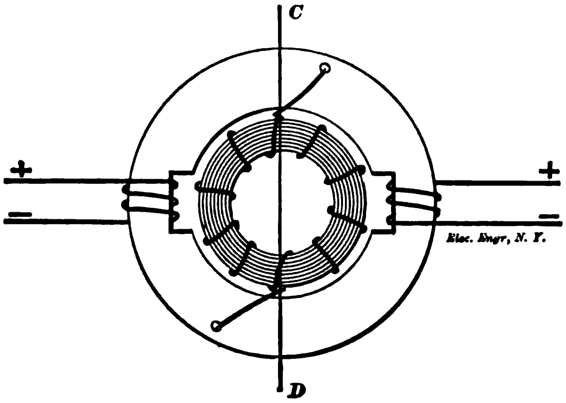

FIG. 4.—DESIGNING ALTERNATING MOTORS.

As $E = \frac{2}{\pi}$, if we find that the magnetizing force of the armature must be n times that of the field, letting N represent the number of ampere turns on the field, and C the number of ampere turns on the armature, it follows that

$$C = \frac{\pi N n}{2},$$

which will give us the required effective magnetizing force in the armature.

In designing the field of an alternating current motor it will readily be seen from the above that the coils must be so disposed upon it as to counteract their self-induction when the proper degree of "reluctance," or permeability, is produced in the armature portion of the magnetic circuit. That is to say, the field should form a divided circuit in connection with the armature, the coil turns being equally distributed on each division. It would be perfectly possible to embody the above principle in a multipolar motor and armature, and I have selected the bi-polar type for illustration only as being less complex in its nature.

The type of field which I consider best adapted for alternating current motors is the simple ring circuit shown in Figs. 1, 2 and 4. Of course, other modifications may be used which would answer practically as well, but this seems to me to be the simplest and most ideal form.

Rotation of the armature can also be secured by short circuiting the two brushes instead of causing a current to flow through the armature coils. The current in the armature coils will then arise from the inductive influence of the field and the proper "reluctance" may be produced by swinging the brushes around to the proper position relative with the field, which will change the direction of the magnetizing effect of the armature coils.

I have watched with much interest the labors of several able experimenters in the direction of designing a motor without the usual form of commutator for the revolving element. While there is no doubt that such a motor is a thing greatly to be desired, I have come to the conclusion, after a careful analysis of the whole subject, that with a current of only one phase, that is to say, without transforming the phase of the current by some means, we must accept the commutator as a necessary function of continuous revolution.

THE FIELD TELEPHONE.

In the usual forms of receiving telephones it has been the practice to polarize the core and diaphragm to the utmost possible extent. A novel form of telephone has, however, been recently devised by Mr. Stephen D. Field, of Stockbridge, Mass., which is both a receiver and transmitter, and in which the inventor proceeds in a directly opposite manner, aiming to have these parts as neutral as possible, though at the same time making use of a magnet of great strength.

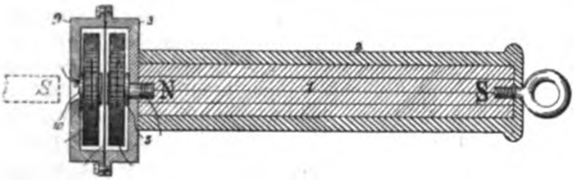
This instrument, shown in the accompanying illustration, is of the polarized type in which the permanent magnet constitutes a practically closed magnetic circuit, and has an open electro-magnetic circuit in which the diaphragm is situated. These two magnetic circuits are so arranged relatively to each other that the currents flowing around the poles of the open electro-magnetic circuit will cause more or fewer lines of force to be deflected from the closed or practically closed magnetic circuit, owing to the peculiar reactionary effect of the currents in the coils of the electro-magnets.

The action will be understood from the engraving, in which 1 represents a permanent magnet, made up of a number of separately magnetized steel bars. At the N-pole of this magnet is placed a cylindrical iron armature 3, attached to the magnet system by the core 5, whose projecting end is screwed into the magnet and on which is mounted a helix, as shown. Across the face of the box armature is placed the diaphragm, which is held in position by the cover of the box. This cover carries on its inner face a projecting tubular core, on which is mounted another helix. The current flows in opposite directions in these two helices, as indicated by the arrows.

By this construction, two paths are opened for the lines of force from the magnet pole N ; one, by way of the walls of the case, with which the diaphragm is in direct contact, and the other, by way of the cores 5 and 10. The latter path is broken by the space between these cores and in this space the diaphragm vibrates. So far as concerns the cores, but very little polarity will normally be found between them in their adjacent ends, since the iron case forms a short circuit or "magnetic shunt" around them, and consequently the diaphragm will not be attracted toward one any more than toward the other by the mere influence of the permanent magnet.

Considering now that current-impulses are passing through the coils, the action will be as follows : We will suppose that the current flows in the coil on the right of the diaphragm in such direction that it tends to induce S-polarity at the front end of core 5. Then a similar polarity will be developed in the front end of core 10. The lines of force will tend to circulate through the two magnetic circuits formed by the diaphragm and the sides of the iron box. Those lines due to the magnetization of core 5 will tend to flow from the end of the core through the box to the diaphragm, and through the diaphragm to and through the air-space between it and the core 5. These lines of force will be opposed in the air-space by the lines flowing through the air-space due to the permanent magnet, but the lines due to the other coil will proceed from the end of the core, to the side of the box, to the diaphragm, to the air-space, and back to the end of the core. These lines will be assisted in the air-space by the lines from the permanent magnet, but will oppose the flow of the latter through the box and the lines from both sources will pass in multiple arc through the diaphragm. The lines of force due to the permanent magnet will therefore follow the path through the box to the diaghragm, through the diaphragm to core 10, and through core 10 to the south pole of the permanent magnet.

It will therefore be seen that one core will be strengthened and the other will be weakened by any given current-impulse which circulates through their surrounding coils, and the diaphragm will, of course, be attracted by the stronger polarity. The amount of this respective weakening and strengthening depends upon the current flowing. The result is a movement of the diaphragm toward one or other of the cores with a force dependent upon the strength of current used, and as the currents in the respective parallel coils flow in opposite directions, their inductive effects largely serve to neutralize their magnetic lag, so that the latter is quite unaffected by the strength of current flowing. In all cases the movement of the diaphragm is exceedingly sharp and prompt whether the current used be very heavy or almost infinitely small.



THE FIELD TELEPHONE.

The action may be perhaps more clearly understood by assuming the presence of a mass of iron, or imagining a phantom pole in front of the mouth-piece, as indicated by the dotted lines.

WICKES' SENSITIVE RELAY.

ALTHOUGH the relay is among the oldest of telegraphic devices it may be said to have undergone practically no change or improvement since its inception. This is more particularly the case with reference to the means of adjustment by which the sensitiveness of the relay can be altered to suit the varying conditions of the line or battery. The present method, consisting in varying the tension of the retractile spring, requires not only some time to effect a correct adjustment, but, besides, gives the operator no indication of the true relation or distance between the armature and the ends of the magnet poles. In other words, there is no way, except by tedious trial, by which a predetermined adjustment can be at once effected and maintained, and the adjustment at the same time made as full as desired.

It is with the object of accomplishing this that Mr. Robert C. Wickes, of New Hamburg, N. Y., has designed the sensitive relay shown in the accompanying engravings.

For this purpose Mr. Wickes employs a pinion A and a gear wheel B, to which is attached a handle C and index hand. An arc shaped slot in the bed plate allows the handle C to move through any angle of a semicircle, which causes the magnet to approach or recede from the armature through a greatly reduced distance, because the pinion A is also a nut gearing with the screw D extending downward from the magnetic yoke. To prevent any lost motion through the action of the several gearings, a helical spring E encircles the screw D and presses permanently upward against the yoke.

It will be evident that if the handle C is moved through the least distance possible by the operator, the motion which is thereby transmitted to the magnet is almost infinitesimal, thereby supplying a very sensitive adjustment. The cross bar F of the armature is pivoted and provided with a spring (not visible) connecting with the small spindle G by a silk thread.

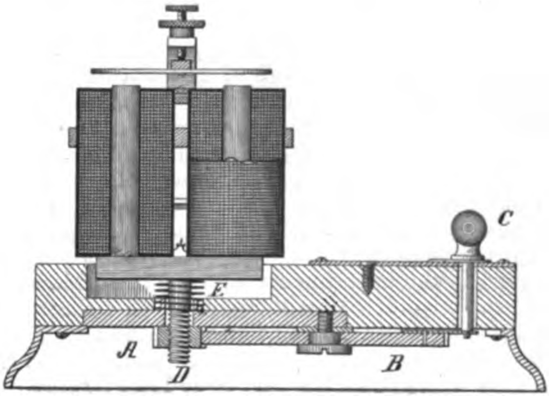


FIG. 1.—WICKES' SENSITIVE RELAY.

By slight modification in the electric connections and with similar advantages, the same construction may be substituted for relays which are common in fire alarm and district telegraph apparatus in which multiple stations are connected with a central station, and in which two local circuits are controlled by the relay armature.

In the ordinary relay, where the thumb screw is employed, the quick and delicate adjustment of the magnet is impossible. With the present construction, however, the handle may be moved throughout the whole semicircle, in the time occupied in turning a thumb screw once.

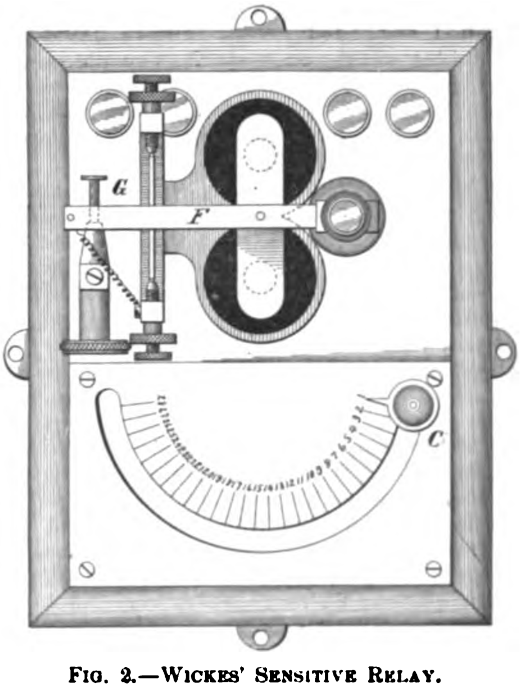

FIG. 2.—WICKES' SENSITIVE RELAY.

ALTERNATING CURRENTS OF HIGH FREQUENCY.—A REPLY TO MR TESLA.

BY

Elihu Thomson

In regard to the comments of Mr. Tesla published in The Electrical Engineer of March 18, concerning my note in your issue of the 11th, I think it desirable that I should make a few remarks. Mr. Tesla appears to infer that my investigations of the properties of alternating currents of high periods must have been subsequent to the note which was published in the *Electrician* a few months ago stating that I had constructed a high period machine. I would say that as soon as that machine was completed I made quite a number of investigations in relation to the properties of these currents, but did not have time to put them in shape for publication.

In regard to the experiments with the incandescent lamp bulb and the strip of filament mounted on a single wire, I cannot agree with Mr. Tesla at all that conduction through the glass has anything to do with the phenomenon it presents. It is well known that an incandescent lamp bulb if held in the hand is capable of acting as a Leyden jar and will receive and retain a charge from a static machine of very high potential, and that a very violent Leyden jar shock, with a long spark, may be obtained by bringing the free hand towards the neck while holding the bulb after charging, as mentioned. If conduction through the glass were a possibility this action could not occur.

Mr. Tesla thinks that I have misunderstood his statement about the limit of audition. From my point of view I think that he has misunderstood my statement about it. He had stated that he had experimented with 10,000 to 20,000 alternations per second. I pointed out that this would correspond to 5,000 to 10,000 complete waves of sound, and equally, I may now say, complete waves of current. The limit he had adopted, or suggested, was about 10,000 waves a second. It is evident that his experimenting with from 5,000 to 10,000 complete waves would be working below this limit of audition, even taking the low value which he had suggested for it. I have heard sounds of 20,000 complete waves per second. The physical cabinet of the Central High School, at Philadelphia, contained, at the time of my connection with the institution, apparatus which enabled a test of one's hearing powers in this respect to be easily made.

I agree with Mr. Tesla that the success of an arc light system depends upon good management; and I include in the term good management, good design, good construction, good supervision, and good commercial work, which includes the ability to stand considerable bad management in the running.

Five or six years ago it occurred to me to try the construction of a dynamo for constant current in which the armature coils were of a highly efficient type, that is, of comparatively short wire length for the voltage and moving in a dense magnetic field. Exteriorly to the coils, and to the field, I had placed (in the circuit of each coil) an impedance coil, which consisted of an iron core wound with a considerable length of wire and connected directly in circuit with the armature coil. I thus obtained, as I thought, the property of considerable self induction along with efficient current generation, and by separate devices, I expected that possibly the effects would be very much the same as those obtainable from the regularly constructed arc apparatus. In this I was disappointed. The effect was to shift the diameter of commutation forward and to lower the capacity of the machine, while the properties otherwise were not so greatly changed. The requirement in the arc machine is simply that there shall be a droop or dip in the characteristic curve at about the point of normal current, and at a rate dependent upon the character of the lamps used with the machine. Differential lamps require for stability less droop or dip than lamps feeding entirely by the shunt or derived circuit. Without doubt, arc machines give better effects when the field magnets are in series, not only on account of the resistance of such magnets, but also because of their self induction tending to smooth out and obliterate vibrations or undulations of current which would otherwise have a direct passage from the commutator brushes to the circuit.

Mr. Tesla has evidently misunderstood my meaning when I spoke of the introduction of a coil of large self induction in series with arc lamps as not affecting their feeding. I had no reference to any instability of current "involving large variations, and occurring at large time intervals," in this case, as the machinery I used was of a stable character and did not give rise to the instability at which he here seems to hint. I meant that a coil of large self induction cut down, or wiped out, vibrations or undulations of current and reduced them to a very slight amount, *i. e.*, prevented them from existing in the circuit, just as such coils will wipe out the waves of speech in a telephone circuit, only the effect here is, of course, on a larger scale.

In relation to the feeding of a lamp which operates by a clutch, I do not deny that a slight vibration of the parts will, or may, benefit the feed, but I think the same slight vibration will benefit the feed of the clock-work lamp also. On this point Mr. Tesla contented himself by simply saying that he cannot agree with me, and that he thinks these vibrations do not at all benefit a clock-work lamp. I disagree with him there, because I think they *must*, as the vibration tends to keep all the moving parts free to act and avoid the sluggish effect of starting friction. In the clutch arc lamps of the Thomson-Houston Electric Company for many years past, the clutch has been attached only to the feed regulating lever by an elastic spring, and the result of this spring suspension or elastic connection (the properties of which I discovered as far back as 1879 or 1880) was that the feeding action by clutches was greatly improved; not, however, because the spring served to damp vibrations, though it undoubtedly did so act, but because it secured an action of the clutch which was equivalent to an automatic slip instead of a free release. In this connection I may mention that I have built and used very many forms of arc lamps of both the clutch and clock-work types.

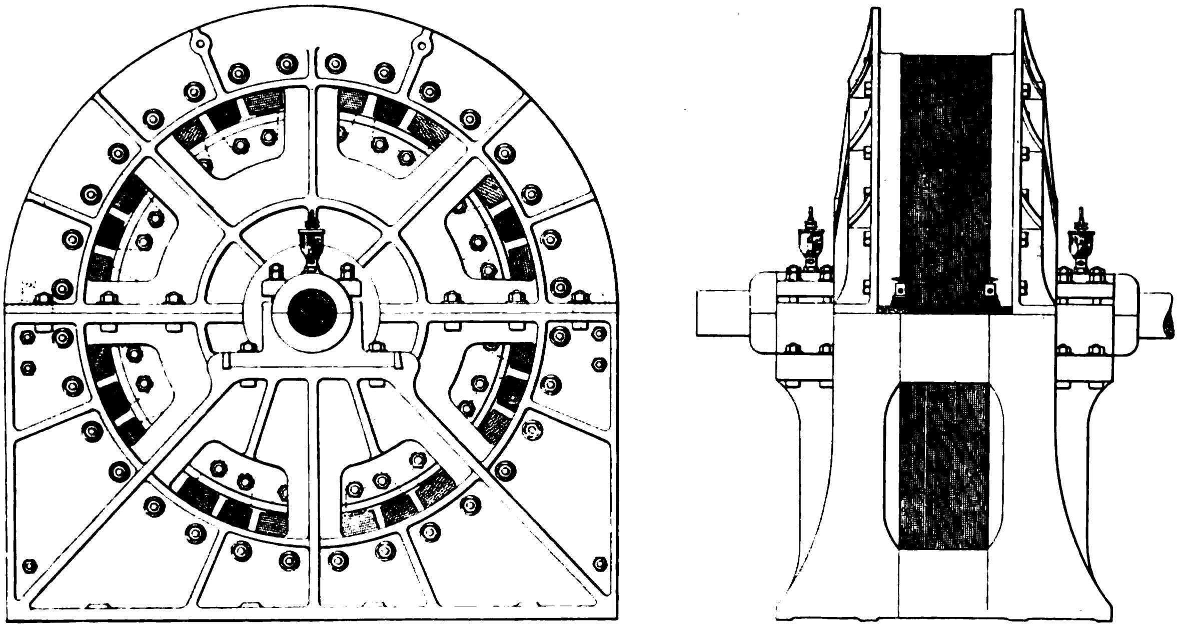
I have frequently operated clock-work lamps of Mr. Wood's construction on Thomson-Houston arc machines, and clutch lamps on machines of the Gramme type, and have, moreover, frequently run mixed circuits of lamps with several types of lamps in the same circuit on either type of machine indiscriminately. The lamps, so far as could be determined by an inspection of the arcs, worked very satisfactorily and in no way different from their normal behavior. I doubt not that there are arc plants in operation in which machines of different makes and types are interchanged, and in which lamps of different makes and different types are found mixed on the same circuit, and while this may not be very desirable always, still there is no reason why the results obtained should not be satisfactory, if the types of apparatus are good, well made and properly taken care of.

While I think it possible that the smaller physiological effect of high period alternating currents may be due to some difference in distribution, still the experiments of Dr. Tatum do not give any indication of such a result, though he sought for it. I cannot say that his experiments were perfectly conclusive on this point. From the fact, however, that the sensory nerves are to be found on the exterior of the animal body in the greatest abundance, and adapted to receive outside impressions, it would seem that the experiments of Dr. Tatum, which show that a greater amount of current at a high period could be tolerated voluntarily, are at least indicative of the fact that the current did not traverse the cuticle where the nerves are so sensitive. In such a comparatively poor conductive material as animal tissue, it appears to me very probable that the distribution of current will be determined largely by conductivity of the layers, and not by self induction to any great extent, especially as the amount or density ot the current which may in any case be supported is so very small.

I confess that my statement as to the motive of my critical remarks may have been out of place. They were elicited, however, by Mr. Tesla having on a former occasion misunderstood my motives and having acted on that misunderstanding.

THE "KINGDON" INDUCTOR DYNAMO.

The accompanying illustrations, Figs. 1 and 2, represent one of the 70 unit alternating current dynamos designed by Mr. J. A. Kingdon for the central station at Woking, England. In this machine the coils, which correspond both to the armature coils and to the field magnet coils of an ordinary alternating current dynamo, are fixed, while the revolving wheel carries a number of laminated masses of iron or inductors, which produce by their motion magnetic changes in the iron cores of the armature or secondary coils. The magnets of the dynamo are built up of a number of stamped iron plates, each plate being of the shape shown in Fig. 3, and having four projecting core pieces. These plates are bolted between two stout cast-iron frames, which also carry the pedestals. The machine is divided horizontally along the centre lines, so that the top can be lifted off and the wheel taken out. There are thirty-two magnet cores projecting from the magnet ring, and sixteen of these are fitted with the primary or exciting coils, and sixteen with the secondary coils in which the alternating current is generated, primary and secondary coils being placed alternately. In the diagram, Fig. 3, the poles marked N S N S are primary poles, and are magnetized by means of an exciter with the polarities indicated. The intermediate poles *n s n s* are the secondary poles, and have their magnetism constantly changed as the inductor wheel rotates. The number of inductors, which consist of a number of stamped iron plates bolted between two steel discs carried on a hub on the shaft, is sixteen, being equal to half the number of the magnet cores.



FIGS. 1 AND 2.—KINGDON INDUCTOR DYNAMO.

The action of the machine is as follows:—In the position of the wheel shown in Fig. 1, the secondary poles have the polarities indicated, being magnetized by the primary poles with which they are connected through the inductors. When the inductor wheel has rotated through one thirty-second of a complete revolution, the secondary poles will all have their polarities changed, being now magnetically connected through the inductors, each with the primary magnet on the other side. The inductor wheel thus acts as a magnetic commutator, and, as it rotates, continually changes the polarities of the secondary magnets. Alternating currents are accordingly generated in the coils wound on the secondary magnets. The polarity of the secondary magnets being changed thirty-two times during each complete revolution, the number of alternations per revolution is thirty-two, being equal to twice the number of the inductors, and being quite independent of the number of primary or secondary coils.

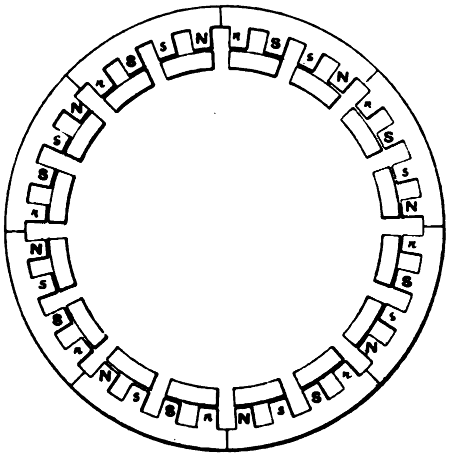


FIG. 3.—KINGDON INDUCTOR DYNAMO.

The dynamos at the Woking central station are coupled direct to triple-expansion engines running at about 260 revolutions per minute. The periodicity of the machines is therefore 70. Each machine is divided into halves, each half giving 15 amperes at 2,000 volts at the speed mentioned. Either the top half, or the bottom half, can be used alone or the two halves may be used together as one machine. When the load on a machine is less than 30,000 watts, one-half only of the primary magnets are excited, and current is taken from the corresponding secondaries. The principal dimensions of the machine are:—Length, 6 ft. 8 in.; height, 6 ft. 8 in.; width, 3 ft. 9 in. The inductor wheel is 4 ft. 6 in. in diameter. The inductors measure 12 in. by 8 in. on the face. The magnets are 8 in. long, and measure 12 in. by 3 in. on the face. The resistance of eight primary coils connected in series is 2.7 ohms, and of eight secondary coils 1.8 ohm. The total weight of the machines is about 7½ tons.

The Kingdon inductor dynamo is manufactured by Messrs. Woodhouse & Rawson, United, Limited, of London, at their heavy engineering works at Kidsgrove, near Crewe, where also the engines and boilers for the Woking central station were made.

THE WESTINGHOUSE AUTOMATIC STREET CAR LIGHTNING ARRESTER.

Besides the thorough insulation of the electric motor and its protection from abnormal currents due to short circuits, provision must also be made to guard against the effects of lightning. A successful lightning arrester must fulfill two prime conditions; in the first place it must act so as to carry off the high potential static discharge without offering an appreciable resistence to the discharge, and, secondly, it must be so constructed that it can break the circuit to earth and take care of successive discharges without requiring further manipulation or personal attention. The first condition is best fulfilled by so constructing the arrester that it embodies no coils, which, by the self-induction created in them, would impede the passage of the discharge. This and the second condition have been combined in a very simple and effective manner in the lightning arrester designed by the Railway Department of the Westinghouse Electric and Mfg. Co., and which is now being mounted on all their electric cars.

The arrester, which is illustrated in the accompanying engraving, consists of two air chambers, A and A^1, having vents, shown at H and H^1, through which the curved carbon B hinged at K, can freely pass, swinging from O to O^1. The carbon point O is set so that it is separated from B, when in its normal position, as shown in the figure, by one-sixteenth of an inch. The distance from O^1 to B, is likewise one sixteenth of an inch, when the curved carbon is in the other chamber. The carbon B is connected to the ground G^1, and the carbon O and O^1 to the motor at D. F is a lead fuse, and E an insulating block, provided with a slot, through which the lead fuse is passed. The points C and D are connected in series with the motor.

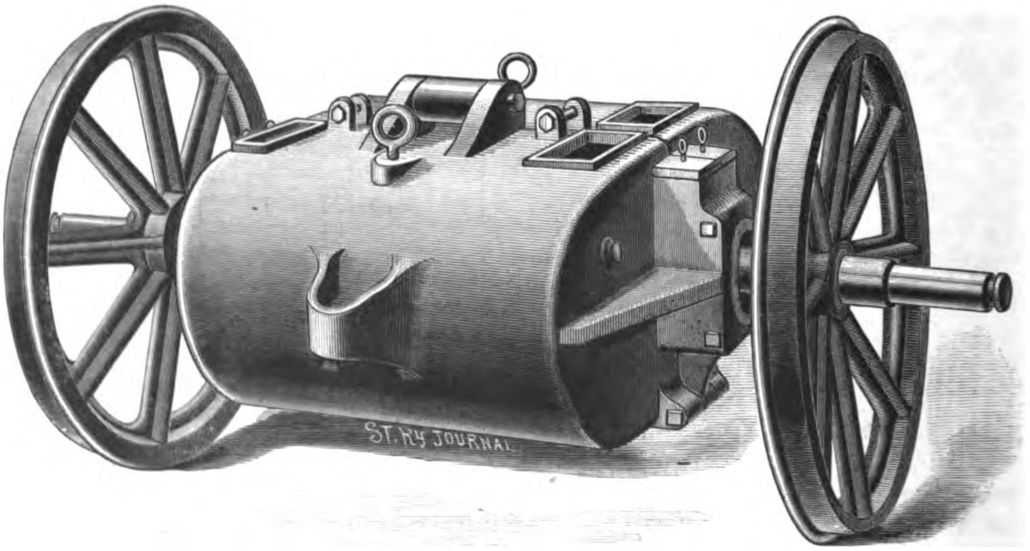

Fig. 1.—Diagonal View of Westinghouse Gearless Motor.—(See page 389.)

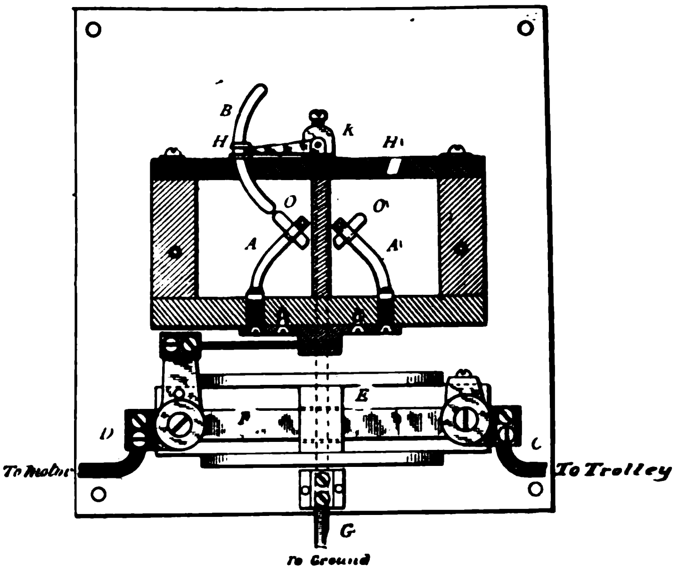
The action of the arrester is as follows: When a discharge takes place, it passes through the lead fuse F, to one of the carbons, O or O^1, depending upon the position of B; then across the air space to the curved carbon B, and from there to the ground, as shown in the figure. The dynamo current, then following, causes an arc to be established between the carbon B, and O or O^1. The heat generated by this arc expands the air in its respective chamber, increasing the air pressure therein, and causes carbon B to be instantly blown from one chamber to the other. This ruptures the arc and adjusts the arrester for the next discharge.



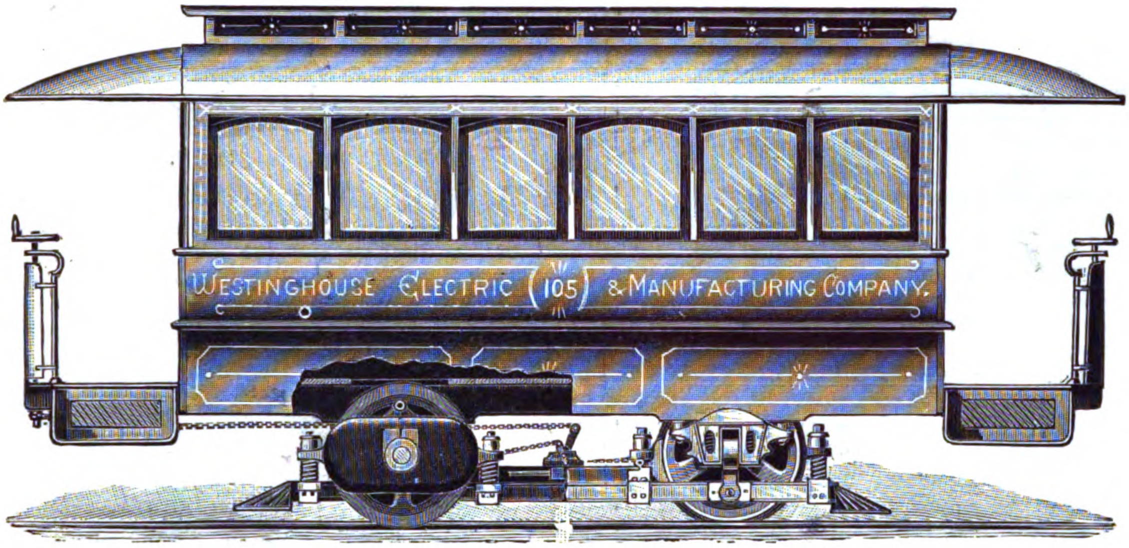
Westinghouse Street Car Lightning Arrester.

In testing upon this arrester, 500 volt and 1,000 volt generators have been repeatedly short circuited through it. In every case the circuit has been instantly broken without injury to the dynamo, and the arrester has as quickly set itself in readiness for future use. In one of the tests made to demonstrate its promptness and reliability, carbons O and O^1 were so adjusted as to touch carbon B, in either of its two normal positions. A 1,000 volt generator was then short circuited through the arrester, which resulted in the circuit being several times automatically opened and closed in one second without injury to either dynamo or arrester.

THE NEW WESTINGHOUSE IRONCLAD GEARLESS RAILWAY MOTOR.

It is but a few weeks ago that we described the single reduction gear railway motor of the Westinghouse Co.,[1] but even in that short space of time a radical change has been effected.

This has been accomplished by mounting the armature directly on the car axle so that no intermediate gear whatever is necessary, thus doing away at once with the objections which have been raised against the various methods of transmitting the power of the armature to the car axle. Two of these gearless motors have recently been built at the works of the company in Pittsburgh, and, after careful tests, have shown results exceeding even those hoped for by the designer.



Westinghouse Electric 105 & Manufacturing Company.

Fig. 2.—Car Equipped with Westinghouse Gearless Motors.

The motor complete, mounted upon the car axle, is shown in the engraving, Fig. 1, and Fig. 2 illustrates a car equipped with one on each axle. The motor has been named the "Ironclad," due to the fact that, it is completely surrounded and protected by the field frame, which forms a natural casing designed with sufficient strength to withstand all shocks and obstructions of the roadbed. The field consists of two symmetrical castings of special iron, sleeved upon the armature shaft or car axle, hinged on top and secured together by bolts. The joints are made water-tight and the bearings are provided with leather cups for the same purpose, which makes it dust proof and possible to operate the motor on inundated tracks. The armature, which is of the drum type, is built upon the car axle. The sheet-iron discs, of which it is composed, being solid and keyed to the axle, give the axle an additional strength, which precludes any possibility of its bending. This arrangement, of course, eliminates all gearing.

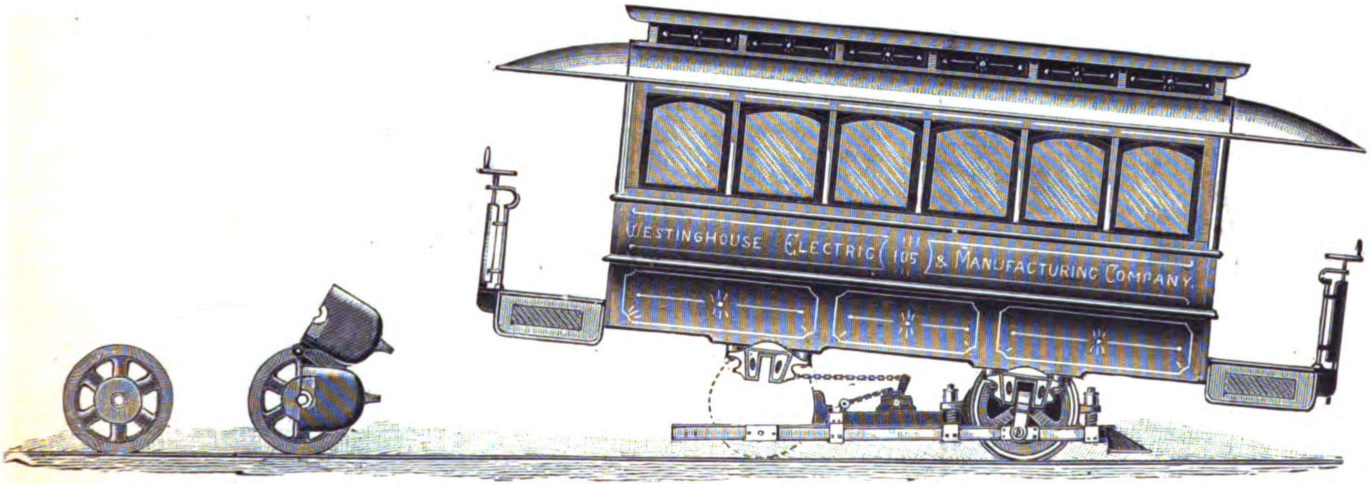


Fig. 3.—Method of Removing Motor.

The car wheels, which are cushioned, are fastened to the shaft by a novel arrangement, which makes it possible to quickly and easily replace them without any special tools or skilled labor.

The armature is but sixteen inches in diameter, with a grooved periphery for the wires, which not only increases the efficiency but holds the wires absolutely rigid. This construction has been found to be of great value for railway work, as the severe strain upon the armatures in starting the car has a tendency to displace the wires when wound upon a smooth surface.

The commutator has been designed with special reference to solidity and durability. It is securely fastened to the shaft, and the bars are connected to the armature segments by short, heavy wires designed to overcome the trouble sometimes experienced from broken connections. The brush holder, which is rigidly fastened to the frame, is of very simple design, well insulated, and easily accessible through openings shown in the engravings, which are provided with water-tight lids.

---

[1] The Electrical Engineer, March 4, 1891.

It will be noticed that the weight of the magnet frame is counterbalanced and cushioned upon two powerful spiral springs which rest upon the cross bars of the truck. These springs prevent the field from rotating and give the motor the necessary flexibility for easy starting. The total depth of the "Ironclad" motor is but twenty inches, giving, with thirty-inch wheels, five inches clearance between the bottom of the motor and the rail.

One point of great importance is the ease and rapidity with which these motors can be changed. When necessary, one end of the car body may be raised by means of jacks or tackle, and by simply unscrewing a nut, the motor can be rolled out on its own wheels, and a reserve motor, ready mounted, can be rolled into its place, as shown in Fig. 3. The fields of the motor can be opened by one man, as shown in the engraving, and the armature at once liberated. For all this no pit is required, and the work can be done intelligently and conveniently.

Actual tests have shown a working efficiency of the new motor of over 90 per cent., which is further substantiated by the fact that after two hours' run with a load of over 20 h. p. the rise in the temperature of the armature and field coils was only thirty degrees above the surrounding air. All sparking has been avoided by the excellent electrical design. This form of motor is free from leakage and external magnetism, and on account of the absence of gears, it is estimated that at least five h. p. per car is gained over the double reduction motors, with a corresponding diminution in coal bills; or, on the other hand, allowing more cars to be operated by the same generating capacity. The wear, tear and maintenance on cars equipped with these motors, it is expected, will be greatly reduced on account of the low speed of the wearing parts, small inertia of the armature and the low peripheral speed of the commutator. The comparatively light weight of the equipment, dispensing with the weight of an elaborate truck, permits of the use of a very light truck, and the "Ironclad" can be adapted for any gauge from three feet up.

This motor, as well as the four-pole single reduction motor, was designed by Mr. Albert Schmid, superintendent of the Westinghouse company, and both bear testimony to his ability.

THE WIGHTMAN TROLLEY ARM.

ALTHOUGH many of the complaints against the unsightliness of overhead electric railway wires are no longer heard, electric railway engineers are still at work improving the present methods of construction, both of the overhead lines and of the attachments by which current is conveyed from trolley to car. Among those who have devoted their attention to this branch is Mr. M. J. Wightman, of Scranton, Pa., who has recently devised the novel arrangement of trolley arm and wire, illustrated in the accompanying engravings.

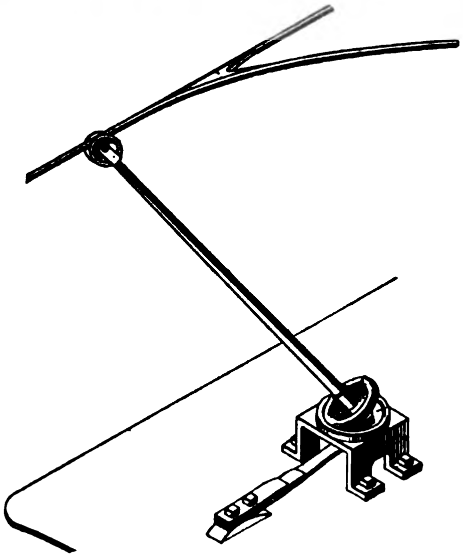

FIG. 1.—WIGHTMAN TROLLEY ARM.

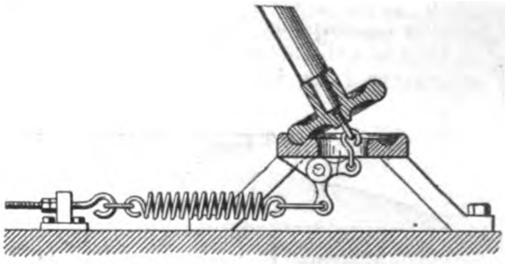

FIG. 2.

As will be seen in Figs. 1 and 2, the construction of the trolley arm is such as to afford it a universal joint at its point of support, and the arm may be readily inclined in any direction and will always have a spring-pressure exerted upon it, tending to restore it to a vertical position. In this way the pressure of the trolley against the trolley-wire will always be in a plane parallel to the wire, and the trolley-wheel will always be carried in a plane parallel to the wire, so that the possibility of derailment is greatly reduced. The point of application of the power exerted by the spring-tension device being at the centre of the fulcrum-disc, the fulcrum will be changed in relation to the power-point during the different movements of the trolley-arm. When the trolley-arm is inclined in one direction and then is moved over into an opposite position, the fulcrum-point is changed from one side of the power-point directly to the other.

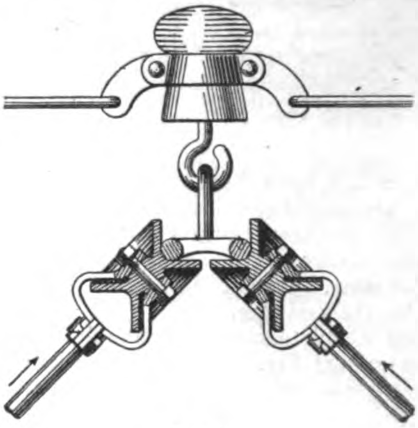

FIG 3.

As the greatest pressure should be in the plane parallel to the trolley-wire, and the least in a plane at right angles thereto, the fulcrum disc and bearing plate are made elliptical in outline. By placing the long axis of the disc and plate longitudinally with the car it will be seen that this result is attained.

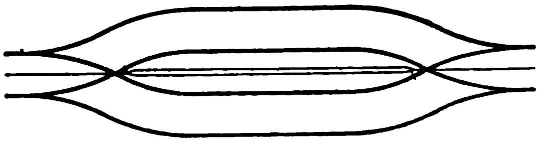

FIG. 4.

It is clear, also, that the trolley-wires, in a two wire system, may be placed very close together between the two tracks, instead of one over each, and may be supported by a single insulator, as shown in Fig. 3, the trolley bearing upon one side of the wire, instead of directly underneath. In Fig. 4 is shown a double turn-out on a single track line, where both branches come to the same point on the main line. It will be noticed that the branching points of the wires are not directly over the branching points of the track, but are so placed that the car may have sufficient lead to deflect the trolley arm from its central position, in order that it may readily run on to the branch wire.

In order to assure accuracy in diverting the trolley, and to facilitate its passage over the branching point, the wire is provided at this point with an enlargement or body, rounded on its sides and bottom, and tapered at its ends.

THE SHORT GEARLESS RAILWAY MOTOR.

Recognizing the value of a method of driving street cars, in which the difficulties encountered with gearing shall be avoided, the Short Electric Railway Co., of Cleveland, O., have designed a type of motor equipment for cars, in which the armature is mounted directly on the axle. In effecting this, special precautions have been taken to relieve the motor of all shocks, due to unevenness in the tracks, and at the same time to afford easy starting of the car.

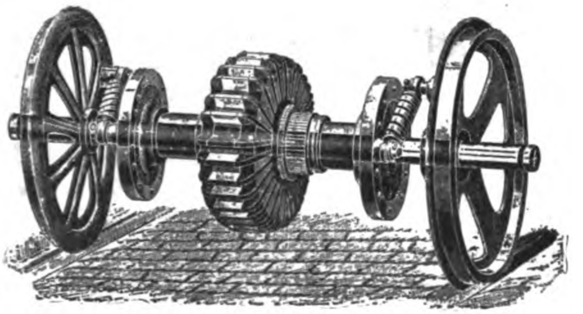

Fig. 1.—The Short Gearless Street Railway Motor.

The manner in which this has been carried out will be readily understood by reference to the engraving, Fig. 1. As will be seen, the axle runs through the armature shaft, which is of steel and is hollow, being 6 inches in outside diameter and 5 inches internal diameter, leaving an air space around the axle. In the centre of this shaft the armature and the commutator are fastened, and on each end of the armature shaft are keyed heavy crank discs, made with an iron hub and rim, and a wooden web similar to the gears which have been used by the Short company. This thoroughly insulates the armature shaft from the rim of the crank wheel. In order to avoid shocks in starting, the crank wheel rim has upon one side a crank pin, as will be seen in the illustration, and the car wheel also has a crank pin, and between the two is stretched a heavy coil spring, capable of pulling, with a very slight elongation, 2,500 or 3,000 pounds. The power of the motor in turning the wheel is transmitted through these springs, and the wheel is gently turned in the direction in which the armature tends to rotate.

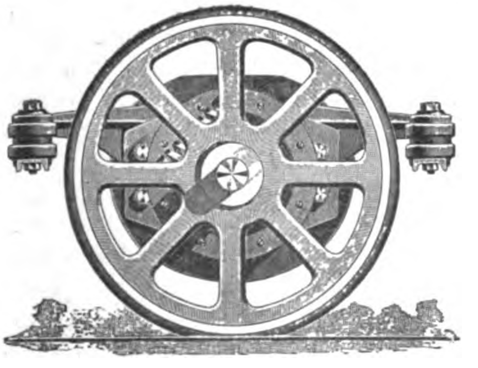

Fig. 3.—The Short Gearless Railway Truck.

Just inside of the crank discs are the bearings of the hollow armature shaft in the motor frame. By referring to Fig. 2, it will be seen that this motor frame is made of two peculiarly shaped castings of steel with arms projecting forward and backward. These arms rest on rubber cushions placed on channel bars which go from side to side of the motor frame. In this way the armature is held up in the frame and away from the axle, and the entire weight of the motor is supported by these spring cushions and by the car boxes outside of the wheels at the points where the car body is supported, none of the weight of the motor falling on the axle inside of the wheels. The spring cushions upon which the motor frame rests are limited in their movements to a fixed distance, so that the inside of the armature shaft cannot come down upon the axle. By these means the motor is carried entirely on springs and this relieves it of shock.

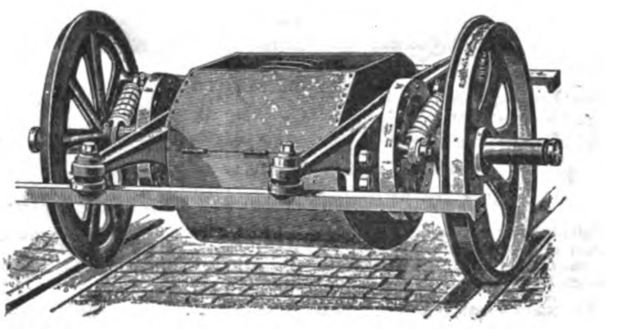

Fig. 2.—The Short Gearless Street Railway Motor.

The motor, it will be noted, is completely covered with a sheet iron casing, completely protecting it from dust and moisture. This casing is a quarter of an inch thick and is made of boiler iron hinged on each side at the top and open in the centre at the bottom, where it is held together with a latch fastening. When a car is run over the pit the casing can be opened out by removing four bolts, and the motor examined from below. The upper part of the casing is open about a foot in width next to the car floor in order to provide good ventilation.

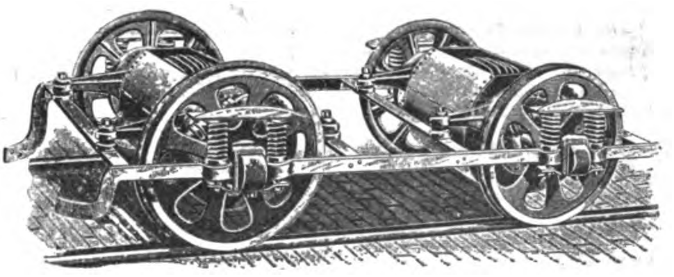

Fig. 4.—The Short Gearless Street Railway Motor.

The engraving, Fig. 3, shows an end view of the motor, and Fig. 4 illustrates a truck fitted with two gearless motors. These motors are constructed entirely of wrought iron and steel, and the weight of the new machine is practically the same as that of the standard motor made by the Short Company, and its efficiency is somewhat greater, especially at normal loads, from 5 to 10 horse power, at which a motor usually runs.

As the speed of the motor ranges only between 100 and 150 revolutions per minute, its action is practically noiseless, and the wear and tear are reduced to a minimum.

The Delaware College trustees, at Newark, Del., have voted to establish a chair in electrical engineering and one in civil engineering. The president of the college is A. N. Raub.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

Vol. XI. NEW YORK, APRIL 1, 1891. No. 152.

The barren premonitions of science have been barren because these seeds of truth fell upon unfruitful soil; as soon as the fullness of time was come, the seed has taken root and the fruit has ripened.
—Josiah Parsons Cooke.

UNDERGROUND ELECTRIC TRACTION.

We publish in this issue the careful and valuable report on underground electric traction for New York city, submitted to the Rapid Transit Commission by Mr. Frank J. Sprague. It repeats and emphasizes the ideas already expressed by Mr. Sprague, and carries the argument several stages further by dealing more specifically with the electrical side of the question. That the tunnel as built on the Greathead system in London is a success is now generally admitted; and there will soon be such a tunnel under the North river of which we can all judge at first hand. But some doubt has existed in the public mind as to the ability of electric motors to handle the heavy traffic, such as would pour up and down a New York road in the crowded hours of morning and night. Mr. Sprague has therefore done well to deal with this point, and his discussion of it is very interesting. After all, the problem has been not to build efficient big motors but economical little ones. One further point might perhaps have been touched on with advantage, and that is the absurdity of some of the comparisons made between the cost of power in operating on the elevated roads and that of the new underground electric system in London. Some criticisms we have seen take it for granted that because it costs a certain sum to carry a given small number of passengers it will cost ten times as much with ten times as many passengers. Such reasoning is obviously foolish and trivial. As it is, the London electric underground is already manifesting an economy and efficiency that command the attention of all who are concerned with the rapid transit question in our great cities. We propose to discuss this matter in detail later.

At the present moment, however, it is striking to observe how the underground electric plan is gaining favor everywhere on its broad merits. Paris is already talking of the adoption of similar methods. As our readers know, the sentiment in New York is extremely favorable, and bids fair soon to be irresistible. And now Boston has taken up the question in its usual thorough way. Following the recent example of the New York Electric Club, the Boston Boot and Shoe Club had a Rapid Transit dinner last week, given to Mr. L. Sterne, demonstrating that the liveliest interest exists in Boston on this subject. The *Boston Herald*, for example, devotes seven columns to an excellent report of the after dinner speeches. Perhaps the most important part of the record is that in which Mr. Henry M. Whitney, who has already done so much for transportation in Boston, directing a system chiefly electrical that now carries 114,000,000 people a year, gave evidence of the close study he has been bestowing on the question. It will be remembered that in order to relieve the congestion of traffic, Mr. Whitney proposed some time ago an elevated electric road for Boston. Meanwhile he has been noting closely the results in London, and in his speech he presented two reports from a special agent now in Europe and a letter from Sir Benjamin Baker, one of the distinguished engineers of the Forth Bridge, and now connected with the underground electric work in the British metropolis. Sir Benjamin states that the South London road "has proved a perfect success," with the result that another road has been authorized to run under Oxford street, from Shepherd's Bush to the Mansion House, a distance of six miles. The plans for this road approximate closely to what will be needed in New York or Boston. The trains will consist of six cars, somewhat larger than the elevated type, seating all told 336 passengers, and weighing with the electric locomotive 120 tons. The speed will be 14 miles an hour, including all stops, the maximum will be 25 miles, and the motors develop 300 h. p. at 13 miles or less. There will be at first 18 trains. It proposed to bunch all the generating power at one end of the line and to equip for a capacity of 5,000 h. p.

All this is very interesting as proof of the confidence felt in the work, and it is confirmed by Mr. Whitney's commissioner, who writes: "The public is delighted with it. They have commenced agitating the question of compelling all the underground roads to resort to electricity as a motive power. The contrast between the old and the new is so great that they do not think they can endure the old very much longer." The same feeling prevails in New York, for even should the Manhattan elevated road obtain the concessions it asks for and ought to get, only a few of the evils will be removed, while others will exist in greater vigor and banefulness than ever, being simply intensified as travel increases and as the clanging structures are hedged in by the abodes of an overcrowded and deafened population.

AN ELECTRIC STREET RAILWAY FREIGHT SERVICE.

One of the most interesting of recent departures in electric street railway work has been the freight service established on the road between Seattle and its suburb, Ballard. Mr. C. L. F. Kellogg, the secretary of the company, informs us that when the road was started, it was thought that a freight car to trail behind one of the passenger cars would pay, as the road runs to the suburban town of Ballard. This notion proved not less happy than true. The freight business soon outgrew the ordinary car, and the company now have a freight car 24 feet long over all, the length of body being 19 feet, 6 in. It is patterned closely after a railroad freight car, and is mounted on a Tripp truck, with two Thomson-Houston 20 h. p. motors. The car makes three round trips per day, and carries from 12 to 15 tons of freight per day. The charges for the class of freight carried will average from 12 to 15 cents per hundredweight. The car delivers freight which can be unloaded quickly at any point on the line as called for. The company are about to establish a freight office at each end of the road. They find that the service pays, over and above salaries of motorman and conductor (who is also express agent), better than any one passenger car, and a great boon, moreover, is conferred on the public of the neighborhood. It seems to us that there is an idea here worth developing in other places. There are roads designed to handle freight, and we hope soon to see the Fall River electric freight road in full operation; but this is a special innovation of unusual merit and utility. The only question or doubt that arises in our mind is as to the ability of the conductor to combine the new functions with his old ones ; but we understand that in Seattle no difficulty has arisen on this score.

GEARLESS RAILWAY MOTORS.

The rapid improvements which have signalized the progress of electric lighting are generally pointed to as one of the most marvelous manifestations of the activity of the workers and inventors of the present age, but even this remarkable record bids fair to be outdone by what might be fairly called the lightning changes and improvements that are going on at present in the department of electric railways. It is but a very short time since the double reduction gear was universally employed on street cars, and the quite recent introduction of the single reduction gear was justly hailed as an improvement, the effects of which would be widely felt. Before the single reduction gear, however, has been firmly or even partially established, we find it strikingly challenged by an arrangement in which no gears whatever are employed. By attaching the armature directly to the car axle, the designers evidently eliminate at once all the drawbacks which are the necessary accompaniment of gears. The methods employed to effect this purpose respectively in the Westinghouse and in the Short railway systems will, we are certain, attract general interest, not only among those whose work is devoted to electric railways, but even those who are only watching the evolution of electric railroading We do not hesitate to say that these new departures will have a tremendous effect in stimulating the development of electric street railways.

LAYING OUT WIRING.

The large number of new men entering the field of practical work in electricity has created a demand for practical rules and methods of construction, and this is more than usually the case among those who are engaged in the wiring of buildings. To be sure, there is an abundance of charts and tables of carrying capacity of wires and other information relating to this subject. While eminently useful in their way, such tables, in order to effect good results, both as regards evenness of pressure and economy in copper, must be backed up by good judgment in laying out the plan of wiring. Judged from this point of view, the article by Mr. Carl Hering, begun on another page, will certainly assist those engaged in wiring buildings in obtaining a correct method of distribution, and enable them to avoid errors which might lead to much inconvenience as well as loss.

Inductive Disturbances in Telephone Circuits.

We print on another page the discussion of Mr. J. J. Carty's Institute paper, by Mr. T. D. Lockwood. Mr. Lockwood takes the ground that Mr. Carty has underestimated the electro-dynamic inductive effects. In this connection it may be of interest, in support of Mr. Carty's theory, to point out the recent phenomena observed on high tension alternating circuits of considerable capacity. It has been shown that under these circumstances the condenser action is especially marked and that the circuits are influenced by static charges which are not met with in continuous current working. When we consider the high rate of alternations produced in telephone circuits, the analogy between the phenomena observed becomes apparent, and it would be well to determine, if possible, the exact extent to which this action shall be given weight in the theory suggested by Mr. Carty.

"Alium" for "Aluminum."

The tendency to drop the extra "i" in aluminium has already become general, but a good deal of dissatisfaction is felt with the shorter form as not being short enough. "Alium" has therefore been proposed, and the suggestion has come from three different quarters, namely, Mr. Eugene Cowles, Prof. Elihu Thomson, and Mr. Oberlin Smith. The latter gentleman, it may be mentioned, read a paper some time ago before the Institute of Mining Engineers, proposing "alium" as a "nickname" and giving some excellent and ingenious reasons for it. The other two suggestions on the subject seem to have been made more recently, but quite originally, that of Prof. Elihu Thomson appearing in a letter in our own columns. We are perfectly willing ourselves to accept "alium," if only as being shorter and easier to write or read, but what is required on such a subject is not further diversity, but unanimity. If all the technical journals the same week began to call the metal "alium," that would settle it. We are ready. The co-operation of the technical journals and the scientific societies on matters of this kind would go far to prevent and remove divergences and to unite usage upon a common standard whether of spelling or of meaning, and there is no reason why joint efforts in this direction should not be made.

A REPORT ON UNDERGROUND ELECTRIC TRACTION FOR NEW YORK CITY.[1]

BY FRANK J. SPRAGUE.

IN presenting my views on rapid transit I shall briefly outline what has seemed to me, after several years of experience and study, to be the best ultimate solution of the question for New York city. For some of the details of, and arguments for, this proposed system, and especially for electrical statements, I am obliged to refer you to attached papers, written at various times, in which I have set forth my views more elaborately than time now allows, and especially as I appear before you in a dual capacity; first, as the advocate of a specific method of tunnel construction adapted to meet our local needs, and second, as an electrical engineer.

The essentials of the system I favor are:

1st. An underground system, because in this way only can we be independent of all surface limitations.

2nd. An iron tubular construction, because it is the strongest, requires less excavation, will give a more perfect roadbed, can be run near the surface, will interfere least with existing or future foundations, and is the only safe system of tunnelling for passenger traffic, where sewer, steam, water, gas, and other leaky and earth saturating pipes exist.

3rd. Independence of way and express track systems on the main line in New York, because rapid transit and freedom from crowding can only be had with a four-track system, with sufficient intervals on one set of tracks between stations to allow of the attainment and maintenance of a safe high speed with any reasonable power.

4th. Independence of tunnel paths for all tracks, because in this way a stronger construction can be had, obstructions more easily avoided, work more readily prosecuted, way routes be so run as to best accommodate way travel, and express routes run by shortest paths subject to express station intervals only.

5th. Way stations between tracks, and express stations at intersections of way and express tracks, the latter being the lower and with access to trains from common platforms.

6th. Electrically operated trains, because the use of the electric motor will be cleanly, noiseless, safe, and more economical, and because it is the only practical method of operating a tunnel system as here proposed at high speeds and for long distances.

7. A continuous train service without necessity of reverse switching.

In brief, then the system I propose is: An independent and way express service; each having double tracks, but having independent paths, run in independent circular iron tunnels, and forming a loop around the city from the Battery to Jerome Park. The express and way routes to intersect or join at different levels at common stations, and the trains to be lighted and operated by electricity. Way trains to have stations about every third of a mile, express every mile and a half, a loop to be provided just south of the Harlem river. There should also be a cross-town two-track system, running beneath the city division, intersecting it on the east and west sides on the Forty-second street line and at the Battery, and making connection with the Long Island, Broadway and Atlantic avenue stations and the street railway lines in Brooklyn, the trunk line depots and street railway systems in Jersey City and Hoboken, and whatever additional underground systems might be developed in the future. A two-track system for this loop would practically provide express service, because on a larger portion of it, that under the rivers, there would be no stops, and the station intervals would be sufficiently long to allow of high speed.

If the elevated railroad system is a permanency in New York, its service can be vastly improved by the running of a double line of tunnels for express service, its route intersecting the elevated system at certain common stations, with elevators running from the elevated platforms to the underground platforms and stopping at street levels, passengers to exchange from one system to the other on one fare; but there is already too little station room, and I believe the success of an underground system will be so pronounced that two such tunnels would be followed by two others and the routes of such an underground system should not be subservient to the elevated routes, which do not properly serve either Broadway, the west side of the city, or the annexed district.

The details of the underground system of tunnelling here proposed, which is known as the Greathead system, but which would be modified for New York city, have been presented to your honorable board by its representative, Mr. Louis Sterne. My interest in it, until very recently, has been purely scientific, and my approval of it unbiased by any connection with it. Within the past week, however, I have somewhat suddenly and unexpectedly been called upon to become one of its active supporters and representatives in this country, and now am such, but it is not primarily in that capacity I appear before you at the present hearing, but rather as an electrical engineer of varied experience, and because I have been somewhat active in creating the present development of electrical railways, and I wish to remove as far as possible the apprehension which I find voiced by some of the daily press as to the availability of electricity for work of such severe character as must distinguish the future rapid transit system of this city, so as to leave the decision of other questions untrammelled. I am led, moreover, to speak particularly of the use of electricity, because in most of the schemes for rapid transit brought to your notice its use has either not been seriously considered at all, or, if it has been considered, its adoption has been simply assumed as a matter of course, while few reasons, either historical or practical, have been given for this assumption, and hence your board has been left without that detail knowledge, so far as it has been published, which would be of service in arriving at a fair conclusion.

I understand that the objections raised are that the science is new, that motors of as large capacity as would be required to handle loads now carried on the elevated railroads have not been used in railway work, that unsuccessful experiments have been made on the elevated system, and there is a doubt about the economy of operation. These objections are not insuperable, and a brief statement of the history of the development of electrical railways of this country, a statement of what has been and is being accomplished, and some general remarks about steam and electrical analogies will, I think, show this.

The first serious proposal in this country for the operation of an electric railway motor by current through the rails was made, I believe, about twelve years ago by Field. One of the earliest private experiments was made on a track at Menlo Park in 1880 by Edison. The Electric Railway Company of the United States in 1883 exhibited a railroad in operation at the Chicago exhibition, and in the same year Daft made experiments at Greenville and Mt. McGregor. In 1884 small roads were built and operated by Daft at Coney Island and in Boston at the Mechanic's Fair, and in 1885 the same inventor opened the first regularly operated line in the United States at Baltimore. In the winter of 1882–3, and the fall of 1883, Van Depoele ran experimental lines in Chicago, and in 1884 and subsequently he operated an exhibition line at Toronto. Afterwards he equipped a number of roads. In 1884 experiments were made by Bentley and Knight, of Cleveland, and Sprague exhibited special motors at the Franklin exhibition in Philadelphia. In 1885, and again in 1888, the Daft Company experimented on the 9th avenue elevated division. In 1886 the Edison-Field interest revived experiments in elevated railroad work, but they were soon abandoned. About the same time Sprague and Johnson experimented on the 34th street branch of the elevated railroad. Two 1,200 lb. motors, each geared directly to the axles of a single truck, propelled two elevated cars up the maximum grade, and many experiments were made to demonstrate methods of electrical braking, etc. In 1888 Field resumed experiments on the same branch. In 1887 Sprague, in New York and Boston, and at St. Joseph, Mo., following out the practical outline on the elevated railroad experiments, started street railway work.

Such is a brief résumé of the work done in this country for the first seven or eight years of the twelve which have elapsed since the first crude suggestions of a working system. Nothing is so marked as the varied character of this work, all of which may be termed experimental. Every one of these experiments in their early form have been abandoned, either because of the development of better machines, more practical methods, or lack of financial support, or because they were ill-timed. Especially is this last reason true of the elevated road experiments which were attempted while the more urgent and commercially important street railway work was almost untouched and the whole science of dynamo and motor construction was undergoing a most rapid evolution. It was not until the years 1887 and 1888 that the movement took place which was the precursor of the present development of electric railways, and which makes the application of electricity to the future rapid transit system of this city feasible. This was the opening, in February, 1888, of the Richmond Union Passenger Railway by the Sprague Electric Railway and Motor Company on the lines of motor development shown by the Sprague experiments on the elevated railroad in 1886. This road, which cost the electrical company $160,000, the larger portion of which was lost, was the first great system operated by electricity, and the difficulties and problems there overcome forever settled the supremacy of electricity as a motive power.

The development, which in the last three years, has followed the inauguration of this road has been almost unprecedented, so that there are now in operation or under contract on the lines laid down at Richmond not less than 325 roads in the United States, England, Germany, Italy, Australia and Japan, requiring over 4,000 cars and 7,000 motors, with 2,600 miles of track, with a daily mileage of not less than 400,000 miles, and carrying three-quarters of a billion of passengers annually. Grades of thirteen and fourteen per cent., distances of six miles or more from the central stations, speeds as high as from 25 to 30 miles per hour for single cars, trains of from one to four cars characterize their operation. Not less than ten thousand people represent the number employed on these roads. Fifty millions of capital invested in this country alone, and a present annual business of not less than eight to ten million dollars on the part of the manufacturing and contracting electrical companies show the present standing of the street railway work.

---

[1] Presented before the New York Rapid Transit Commission, March 15, 1891.

These figures should be sufficiently significant, but it may very properly be asked, "Have there not been many troubles? Are not changes being constantly made, new machines being designed, and will not the building of larger machines than those already made be attended with some difficulties?" It would be folly to reply to these questions except in the affirmative, but that is true of the development of every machine. Many of the difficulties incurred are due to the rapidity of the commercial development which has made it necessary for the manufacturing companies to put out motors in great quantities without correcting the troubles which must necessarily appear when machines representing a new art are put into practical operation under the most varied and severe circumstances.

But the development of the motor of the future is clearly outlined and will be most rapidly carried out. Let us consider in this connection the existing steam locomotive and the development of the dynamo machine. Every locomotive is really a combination of a boiler and two engines, independent in all things, save that they are connected to a common driving axle, which two engines continually work under a load which varies in every portion of their cycle. The principles governing each of these engines are precisely the same as govern the operation of any other steam engine, but although thus similar, and although there are hundreds of forms of steam engines, high speed, low speed, simple, compound, triple and quadruple expansion, condensing and non-condensing, built for various classes of duty and with a view of getting a certain output with a certain expenditure of coal, the use of which being determined largely by the relative value of coal economy and other commercial considerations, common practice has outlined one general type of steam locomotives, the one with which we are all familiar.

The varieties of types of steam engines do not, however, cast any doubt upon the adaptability of steam engines for traction, nor does the fact that the elevated railroad carry engines of a combined capacity with two cylinders of 185 horse power, which is the capacity demanded for its particular duty, alter the fact that any standard locomotive works is perfectly able to build locomotives of 1,000 horse power, or as much more as may be required, and that, too, under limitations which do not exist in the building of electric motors, because the locomotive has to carry its own boiler, furnace, water and fuel.

The fact that electric motors of large size have not been commercially introduced for railway work is simply because there has not been a demand for them; the art, both scientifically and commercially considered, has not warranted the experimental expenditure demanded in the evolution of the larger types of machines. The commercial sense dictates this development, and as soon as your board shall have determined on a system of rapid transit which shall require the use of motors of large capacity, you may rest assured that such motors will be promptly forthcoming. Your decision will give an impetus to this development because it will open the opportunity which will be eagerly grasped by hundreds of intelligent, enthusiastic electrical engineers, backed by abundance of capital. All that is necessary, I repeat, for the creation of this larger type of machines, is that the commercial need should exist for it. This is the history of every mechanical appliance, no less the steam engine than the electric motor. Who would have dreamed a few years ago of such magnificent specimens of engines as the 15,000 horse power triple expansion engines which to-day propel our fast ocean steamers?

Already steam engines are being built of size and capacity to accommodate the demands made upon them by the dynamos of the future. The machines of from 200 to 400 horse power capacity which are now being built in this country are of a capacity not called for and not seriously considered some years ago. In Berlin, in the finest electrical stations in the world, dynamos of 500 horse power capacity are driven in pairs by engines of 1,000 horse power, and the whole construction shows that as much reliance is placed upon the perfection and durability of the dynamo as upon the engine itself. A striking comparison, both as to size, appearance and simplicity of dynamos and engine, is shown by the most casual glance at one station, a partial photograph of which I have here; the dynamos have got a far greater temporary capacity than the engines themselves.

I may say in passing, that this photograph will give an approximate idea of one of the units which I have in mind for the future central station of the electric rapid transit system of New York. Two stations, each with three units as here shown, would effectively handle the entire traffic of the Third Avenue Elevated Railroad, with its 63 trains and locomotives of an aggregate capacity of 12,000 horse power. At the Deptford station, in London, engines and dynamos of 10,000 horse power capacity are under construction. If dynamos of these capacities can be built, in the operation of which millions of dollars are invested, what is there to prevent building motors of any required capacity to meet your demands? There is none.

After all, what is a dynamo and what is a motor? Nothing more or less than the application of two different names to the same piece of apparatus, each of which specifies the purpose for which it is used. When we apply power to this machine and produce by its rotation electrical energy, we call it a dynamo, and when we put current through the same machine and by its rotation apply power to a driven shaft, it is a motor. Its electrical function is absolutely the same in both cases; its efficiency of conversion almost identically the same, and very high. As there are many types of dynamos varying in form to meet commercial and manufacturing demands, so there are various forms of motors, and when this machine is so used, especially for railroad work, on account of the rapidly varying and difficult character of the duty, the necessity of comparatively light weight, and freedom of accessibility for change of parts in emergency, it is advisable to have a special construction; but even here, the electric motor has a freedom of application entirely denied to the steam locomotive, which must work within certain prescribed lines.

After all, how small the advance which is necessary to get the required capacity for operating any rapid transit system required. The elevated locomotives, handling trains of a gross weight of 90 to 105 tons, carrying sometimes as high as 500 passengers, and capable on a half mile stretch of attaining a speed of 30 miles an hour, have two cylinders, each of about 90 horse power. Thousands of street railway motors of 15 and 20 horse power are in daily operation, nearly always in pairs.

Double the lineal dimensions of a 10 h. p. motor and it becomes an 80 h. p. motor, and two of such machines controlled by a single switch will do the work of an elevated locomotive; but not only two but one hundred, if necessary, of such machines can be controlled by a switch. Double the lineal dimensions of a 20 h. p. motor and it will become a 160 h. p. motor and will easily work up to the capacity of the elevated locomotive. This increase of capacity with increase of dimensions is an imperative law and governs many other classes of machinery. Stationary motors working up to 50 and 100 h. p. are now rapidly being adopted, and much larger ones will soon be in use.

I repeat, there need be no hesitation on the part of your board on the question of electric traction, because of any apprehension that the electric motor development will be found wanting when demanded.

On the City and South London Road the entire central station and electric motor equipment was finished before the tunnel was ready for use, notwithstanding the fact that when the tunnel was originally designed a cable was intended for the motive power.

But I will go further than mere assertion that the required development will take place, and I will, as far as may be, determine the matter by reference to that criterion which alone governs almost all decisions of this character, the possibly hard, but the entirely just, one of dollars and cents, for I am ready, if a rapid transit system be adopted requiring the use of the electric motor, to undertake the entire contract for the necessary steam and electrical equipment for not less than fifty way and express trains operated as I have outlined, under satisfactory guarantees of efficiency and cost of operation as compared with steam practice.

THE FOURTH AVENUE TUNNEL.

The N. Y. State Railroad Commission, having completed the investigation of the accident in the tunnel, recommend, among other things, improvement of the audible signal at the home signals, and the adoption of the torpedo in addition thereto; constant inspection of the lights and wires moving the signals, and the use of an electric device to show to the operator in the cabin the position of the signals; the adoption of a rule that no engineer or fireman shall be permitted to run a locomotive through the tunnel until he shall have a certificate of perfect eyesight and perception of color, and a reduction of speed to fifteen miles an hour, the rate to be still further reduced under unfavorable conditions.

It is proposed to string some incandescent lights through a section of the tunnel and note the effect.

THE INCANDESCENT'S STILL SMALL VOICE.

One of the late London inventions, says an exchange, is the "silent call," an invention in connection with electric lighting. Two lamps are suspended outside the building, one red and the other green, and by pressing a button in the entrance hall, one or the other of the lamps can be lit at will. The red light summons a four-wheeler, and the green a hansom cab.

ARC LIGHTS ON THE NORTH POLE.

Hammerfest, the most northerly town in Europe, and situated within the Artic circle, is one of the first places in Norway to be completely lighted by electricity. A waterfall a mile distant from the town furnishes the power to run the dynamos. The electrical plant is of the Thomson-Houston make.

INSTITUTE DISCUSSION ON INDUCTIVE DISTURBANCES IN TELEPHONE CIRCUITS.[1]

If Mr. Carty continues to hold the views of two years back, I understand him to believe that electrostatic, in contradistinction to electromagnetic, induction is chargeable with the major amount of discredit as an agency in disturbances on telephone lines; or, at any rate, that it is a much more important agent in the development of such disturbance, whether noise or cross-talk, than has been supposed.

From long experience and observation, it appears to me that the several agencies in causing disturbing phenomena in telephone circuits which manifest themselves in the telephone receiver preponderate largely in accordance with the conditions of the circuit; that the environment (to use the language of social science) of a telephone circuit has a good deal to do with its behavior. Thus a line which has considerable leakage uniformly distributed throughout its length will suffer very little from electrostatic induction either manifested as a disturbance or as a retarding agency; not because the electrostatic induction is not exercised, or is not present; (or to put in a more modern and I think a more correct phraseology) not because inductive circuits are not formed; but because there being, by virtue of the leakage or poor insulation, an opportunity for a number of short cut or cross conductive circuits, these are utilized for the conduction of the electricity, permitting the establishment of equilibrium or discharge, at the expense of the utilization of the inductive circuits which tend to retain charge. The phenomenon exhibited, is comparable to a gallon vessel, say, in which liquid may be poured; but which has a number of holes bored through its sides. The vessel has a capacity of one gallon, but, being leaky, does not hold its charge, and the said charge is dissipated as quickly as it is formed. In this case, leakage tends if accentuated, to become the chief adverse agency, as not only does a leaky circuit dissipate induced charges quickly, but it also permits stray currents which may disturb, to come on the lines from external points.

As a matter of fact the several disturbances upon telephone lines are due to a large variety of causes. It is customary to say that the telephone is an extremely sensitive electroscope, or galvanoscope; and that it will take cognizance of almost infinitely small currents. This statement, however, should be made with some reservation.

The more correct statement is, of course, that that the telephone is a sensitive indicator of *changes* in electrical currents.

A current may be caused to circulate through its helices which is sufficiently strong to make them warm, but if that current be steady, it will not be able to produce a sound in the telephone. Telephone disturbances then, broadly stated, can result only from changes which occur in the electric condition of the circuit within which the telephone is included, and these changes may be produced by conduction from other electrical organizations; by electromagnetic induction, sometimes brought about by changes going on in substantially parallel circuits, and sometimes caused by the mechanical motion of the disturbed circuit itself in a magnetic field; as when a line swings across the magnetic meridian of the earth; and by the successive charges and discharges which cause the alternate completing and disrupting of electrostatic inductive circuits.

If we exhaustively examine the literature of the subject we shall find that the idea that electrostatic phenomena are concerned in disturbances of telephone and telegraph circuits, is by no means new. Mr. Culley presented a paper once upon this subject, before the Society of Telegraph Engineers; which paper, together with a most instructive discussion, is published in the journal of that Society, and Mr. Preece and myself from time to time have also repeatedly referred to it. It is due, however, to Mr. Carty to say that his considerations and researches in this line show him to be an original and independent thinker and observer, and that I have found his work to be instructive in the highest degree.

I think while he is undoubtedly right in attributing a large share of inductive disturbance in telephone lines, that he does not give sufficient weight to the equally undoubted fact, that electro-magnetic induction is also an important factor; and that as I have already pointed out, the conditions of any individual circuit largely govern its action. An interposed plate or an envelope of metal between the disturbed and disturbing circuits, will, if sufficiently thick, and if united to earth, screen so much of the induction as is electrostatic in its origin; but it will not screen electro-magnetic induction; and thus, whenever it is worth while, the sources of inductive disturbances can be analyzed. And while the inductively neutral metallic circuit,—the circuit with two wires closely adjacent and twisted together,—is indeed a specific against electro-magnetic inductive disturbance; it also tends to increase the retarding effect of electrostatic induction exercised between the two wires of the circuit.

Some of the considerations which tend to delay the universal employment of metallic circuits in telephony are, however, that there are an immense number of wires even when but one is used to a circuit; that twice the number of wires means twice the number to get out of order, to cross, break and leak, and consequently twice the number to take care of, and handle.

I hardly think that sufficient thought is given to these matters by many who talk glibly about the necessity and essentiality of using metallic circuits only, for all classes of telephone work.

In conclusion I wish to suggest, that inasmuch as the telephone only notes electrical changes, we cannot accurately say that sounds can be produced in it by electrostatic charge.

---

[1] Abstract of a communication, by Mr. T D. Lockwood, on Mr. J. J. Carty's paper read before the American Institute of Electrical Engineers. See THE ELECTRICAL ENGINEER, March 25.

SOME FIGURES AS TO LIGHTING RATES.

As there is general interest in the question of rates paid by cities for lighting purposes, the following tables, compiled from reports made last fall to a committee of the Scranton Pa., city council, will be of interest. The first table is from cities lighted under contract by private companies.

Name of Place.	No Lights.	Cost per annum pr. lamp.	Hours Lighted.
Alliance, O.	8	$141 00	All night
Janesville, Wis.	8	100 00	To midnight
Cedar Rapids, Ia.	10	125 00	Except moonlight
Gloucester, Mass.	13	96 00	To 12 o'clock
South Bend, Ind.	14	100 00	To 12 o'clock
Union City, Ind.	22	95 00	Except moonlight
Ashland, Pa.	23	125 00	All night
Keokuk, Ia.	24	126 00	Except moonlight
Ogden, N. Y.	24	133 36	12 o'clock
Bath, Me.	27	100 00	5 all night 12 midnight
Keene, N. H.	27	100 00	To 12 o'clock
Chattanooga	30	121 66	All night
Wooster, O.	30	108 00	All night
Concord, N. H.	39	100 00	To 12 o'clock
Waltham, Mass.	32	127 00	To 1 o'clock
Jacksonville, Ill.	32	100 00	Except moonlight
Charleston, S C.	36	144 00	All night
Fond du Lac, Mich.	38	72 00	All night
Lockport, N. Y.	37	80 00	Except moonlight
Asheville, N. C.	37	100 00	To 2 a. m.
Burlington, Ia.	39	130 00	To 2 a. m.
Taunton, Mass.	44	110 40	Schedule moon
Yonkers, N. Y.	45	60 00	All night
Wilkesbarre, N. Y.	48	144 54	All night
Cortland, N. Y.	50	50 00	To 12 o'clock
Columbus, Ga.	50	108 00	Except moonlight
Vicksburg, Miss.	50	114 00	" "
Selma, Ala.	50	120 00	" "
Fall River.	60	180 00	All night
St. Paul.	50	127 75	To midnight
Lima, O.	58	100 00	To 1 o'clock
Pottsville, Pa.	58	105 00	All night
Portsmouth, N. H.	60	100 00	" "
Adrian, Mich.	63	100 00	" "
Winona, Minn.	63	125 00	" "
Hornellsville, N. Y.	64	100 00	" "
Springfield, O.	64	130 00	" "
Battle Creek, Mich.	65	85 00	To 12 o'clock
New Britain, Conn.	66	100 00	To 12 o'clock
Paterson, N. J.	70	100 00	All night
Eau Claire.	70	110 00	All night
Somerville, Mass.	70	185 00	1 o'clock
Burlington, Vt.	70	116 00	12 o'clock
Logansport, Ind.	75	100 00	All night
Mansfield, O.	77	75 00	All night
Saginaw, Mich.	80	100 00	To 3 a. m.
Joliet, Ill.	80	120 00	To 12 o'clock
Norwalk, Va.	82	70 00	To 12 o'clock
Wichita.	83	83 33⅓	All night
Northampton.	83	75 00	To 12 o'clock
Petersburg, Va.	82	96 00	All night
Newburg.	97	111 00	All night
Binghamton.	99	140 00	All night
Indianapolis	100	80 00	All night
Waterbury, Conn.	100	142 85	All night
Racine, Wis.	100	70 00	All night
Sedalia, Mo.	100	87 00	Schedule moon
Atlanta, Ga.	100	120 00	All night
Allentown, Pa.	101	100 00	Except moonlight
Galesburg, Ill.	104	105 00	All night
Boston.	105	180 00	All night
Sandusky.	115	100 00	All night
Milwaukee.	130	150 00	All night
Chillicothe, O.	121	80 00	All night
Richmond, Va.	133	146 00	All night
Lancaster, Pa.	139	124 10	All night
Zanesville, O.	140	70 00	Except moonlight
Norfolk.	155	100 00	All night
Reading, Pa.	156	146 75	All night
Akron, O.	170	78 00	All dark nights
Youngstown, O.	180	72 50	All night
Massillon, O.	180	70 00	All night
Jackson, Mich.	180	88 89	All night
Mobile.	181	91 00	Schedule moon
Bloomington, Ill.	211	108 00	All night
Poughkeepsie.	212	123 00	All night
Lafayette, Ind.	214	50 00	All night
Terre Haute, Ind.	232	70 00	To 3:00 a. m.
Harrisburg.	270	90 00	All night
Troy, N. Y.	271	158 00	All night
Springfield, Mass.	300	83 33	All night
Scranton, Pa.	322	90 00	All night
Toledo, O.	400	100 00	All night
Minneapolis.	480	150 00	Except moonlight
Philadelphia.	800	177 00	All night
New Orleans.	1,010	130 00	All night
New York.	1,357	90 00	All night

In all the above cities, with the exception Newbury, Norwalk, Richmond, Va., Northampton, Mass., Taunton, and Concord, the lamps are 2,000 candle power, and in these cities 1,200 candle power.

As stated, the above figures are for cities where the lighting is done by contract by corporations. The following are the figures in cities where the city owns its own plant:

Name of Place.	No. Lights.	Cost per year per Light.	Hours Lighted.
Martinsburg, Ind..	80	$ 40 00	To midnight
Grand Ledge......	32	62 00	To midnight
Huntington........	50	48 61	All night
Decatur, Ill........	52	60 00	All night
Dunkirk, N. Y.....	55	36 50	All night
Paris, Ill............	60	36 60	Except moonlight
Easton, Pa.........	64	100 00	All dark nights
Aurora, Ill.........	75	56 00	Except moonlight
Painseville, O......	80	35 00	Except moonlight
Madison, Ind......	85	48 00	All night
Lewiston, Me......	96	42 00	All night
Hannibal, Mo......	96	52 00	All night
Little Rock, Ark...	110	47 50	When dark
Bay City, Mich.....	134	60 00	All night
Topeka, Kan......	184	54 00	Eight hours
Topeka, Kan......	184	72 00	All night
Chicago............	292	55 60	All night

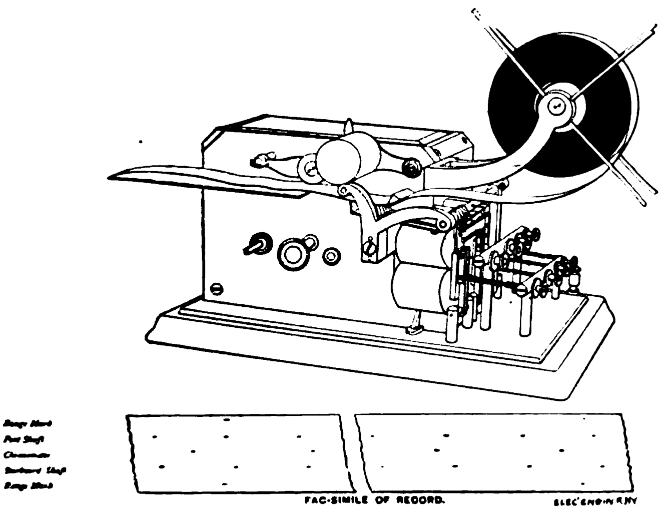
It should be added that many of the figures in the second table are utterly misleading and untrue, as no allowance is made for various items of charge and debit, and in some cases none for even necessary fuel or attendance. It is claimed, for example, that in Chicago the cost set down as $55 is actually in the neighborhood of $100. At a recent hearing on the subject in Boston, Mr. M. J. Francisco said that Chicago maintains four stations, but they do not supply the whole of the city, and now $100,000 is asked for extensions; the cost in one station about which he had collected facts, was over $100 a year per lamp, without counting in all the items of expense that should be properly charged to the electric light. The other places cited showed higher cost than this, with a few exceptions, the cost in most small cities being about $120 per lamp per year. Marietta, O., and Parkersburg, W. Va., only 12 miles apart, have about the same conditions for lighting; Marietta's municipal plant costs 4¼ cents per night, and Parkersburg pays to a company only 2¼ cents. Mr. Francisco also called attention to some other considerations affecting the question; if a private company, through accident, lightning or storm, cannot furnish the light it has to give a rebate to the city, and the company has also to meet expenses from wires blown down, etc. No estimate of such expenses has been put into the cost as given by the advocates of municipal ownership.

REGISTER FOR SPEED TRIALS.[1]

BY ASSISTANT ENGINEER W. D. WEAVER, U. S. NAVY.

The apparatus, a description of which follows, was devised to carry into effect Engineer-in-Chief Melville's method of making speed trials.

An ordinary chronograph was first suggested, but the delicate nature of such instruments and the great expense for one suitable for use aboard ships, made its adoption impracticable. While making inquiries about forms of chronographs, it was learned that a number of Morse registers had been fitted with two pens for use as chronographs in college laboratories, and as a result the present apparatus was devised.



FIGS. 1 AND 2.

While in principle a Morse register, it differs in being more carefully constructed; in having a governing attachment, by means of which the speed of the paper may be varied; in having five pens instead of two, and in the method by which motion is given to the pens by the magnet armatures.

The essential principles of the apparatus, which is shown in Fig. 1, are as follows:

By means of a clock train a paper tape is passed above the pens, on which, at each electrical contact, a mark is made by one of the latter, as shown in Fig. 2.

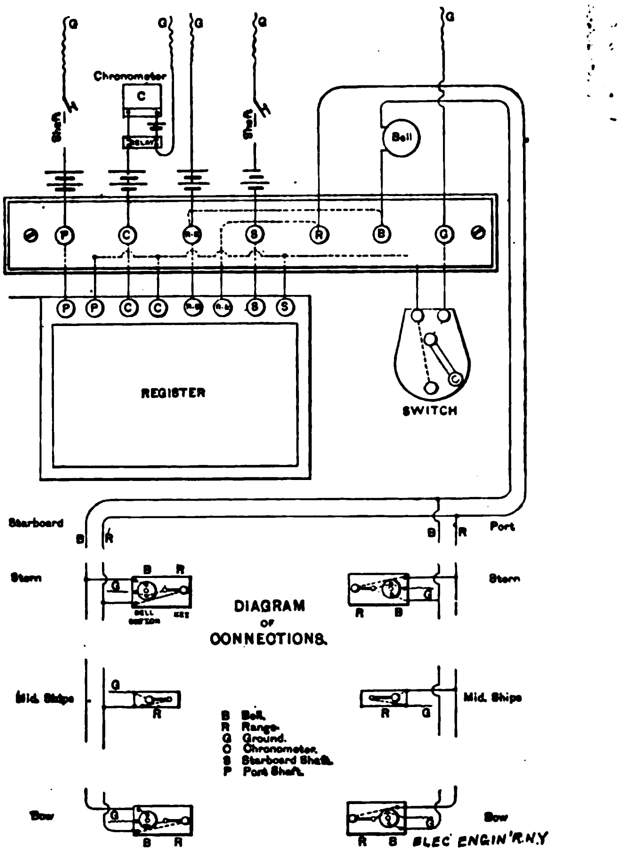


FIG. 3.

To an arbor of the train is attached one of three inertia governors, by means of which the speed at which the tape is paid out can be regulated. One of these permits a motion of one-half inch per second, another of one inch, and a third of one and one-half inch per second; running free, the tape has a speed of about two and one-half inches per second.

In order that the speed may be as regular as possible, a Geneva stop is connected to the barrel of the main spring, so that only that part of its length may be utilized in which the elastic force is approximately constant.

The five pens are actuated by four magnets. To one of the magnets is led the interrupted current of an electric chronometer, to two others the currents established by contacts on the port and starboard shafts, respectively, and through the fourth a momentary current is passed at the instant of arriving on and leaving the measured mile course. To the latter armature are connected two pens which mark on the two margins of the tape, thus permitting a datum line to be drawn from which are measured the fractional parts of time and revolutions.

The instrument will run out 125 feet of tape with very little variation of speed. This, with the inch-per-second governor, corresponds to a time of 24 minutes. It should be remembered that the requirement of the clockwork is that the speed of the tape shall not appreciably vary during each period of a second, and that variation with this instrument is infinitesimal.

Owing to the powerful spring and few arbors in the train the probability of the instrument becoming deranged is small. During a large number of experiments, some of them purposely made very trying, no hitch whatever occurred.

An essential feature is the "piano action" motion of the pens. Through this the time of contact with the tape is infinitesimal, thereby avoiding friction against the tape at a critical point—a defect of the two-pen chronograph.

As only intervals of time, revolutions, and space were required, not the absolute time of passing a range mark or of a given revolution, the pens, for simplicity, are made to mark at a "make" contact; and as the chronometer marks at a "break" contact, a relay must be interposed between it and the register.

---

[1] *Journal of the Amer. Soc. of Naval Engineers.*

Should it be considered that the accuracy within the limits of measurement may be improved by using a "break" contact, it will only be necessary to change the windings of magnets and slightly change the motion to effect this. It is very doubtful, however, if this change would measurably, if at all, increase the accuracy.

For trial trips it is proposed that there shall be three range observers, one at the bow, another amidships, and a third on the poop. As the ship enters on, or leaves, the range course, the observer will touch a key and a record will be made on the tape; in addition, there will be a bell button at the bow and stern to notify, from twenty to thirty seconds before the ship enters the course, the one in charge of the instrument that he may set it in motion and switch on the battery.

The diagram of connections, Fig. 3, shows the manner of setting up the register and will make clear the method of operation.

The tape may be measured to hundredths of a second, and, with a shaft making one hundred and twenty revolutions per minute, fiftieths of a revolution. The marks on the *fac-simile* of record are longer and heavier than on an actual record, and the illustration of the register is inaccurate in several respects, having been made by the engraver from a photograph without proper supervision and correction.

With the instrument made for the Bureau of Steam Engineering were furnished special keyboards, contact brushes, connection board, etc., and drawings and specifications; so that the apparatus could be set up complete for use in a couple of hours after arriving aboard ship, or in the time required for wiring.

TRANSFORMER DISTRIBUTION.[1]

BY J. SWINBURNE.

THE distribution of electrical power by means of alternating-current transformers can hardly be considered to have reached its final state, and though it may be somewhat difficult to say what system will be in general use ten years hence, there is little doubt that present practice will be largely superseded.

The method now in vogue is simple: It consists of running several independent dynamos, each with its own engine; each dynamo supplies a few high-pressure mains, which branch off, and supply transformers placed in the houses, or wherever light is required. This system, admirable for country towns or straggling villages, is hardly likely to be permanent anywhere else. It has many disadvantages. Except that all the dynamos and engines are in one building, it is nothing more than a collection of little independent installations. In cases of a breakdown, there is a stoppage till new arrangements can be made at the station. In addition to this, great lengths of high-pressure conductor are required, and this leaves openings for breaking down of insulation. The introduction of high pressures in private houses is dangerous if not well managed, and is in any case expensive, demanding compliance with all sorts of regulations, rendered necessary for the security of the public. The greatest drawback to the present system, however, lies in the waste of power in the transformers themselves.

It must be borne in mind that in spite of the drawbacks of the present system of putting transformers in houses, it may be, and probably has been, advisable for electric light companies to begin on that system, even in such places as London; but I do not think such an arrangement will pay in the long run, and a time will arrive when the mains will have to be changed and a low-pressure supply system substituted.

PARALLEL RUNNING ACCORDING TO ORTHODOX HYPOTHESIS.

To begin at the beginning of my somewhat extensive subject, the first question is that of running machines in parallel. There are few matters of greater importance to engineers, and few on which opinions differ so widely. One says that machines will not run in parallel unless they have large self-induction; another that it is necessary to have iron in the armatures; another that they will only run together if they have no self-induction, or as little as possible. Others say that there is no difficulty in running them in parallel. No engineer who employs direct currents denies the advantages of running the machines in parallel; if independent running is advisable in alternate systems, it is equally advantageous in the case of direct currents, and direct-current stations should have separate circuits for each little district, each district being run by one dynamo. I do not think, therefore, independent running is advisable.

It is necessary first to get a clear idea of what is required for parallel running. It is not exactly the same as the case of alternating motors, neither is it the same as two machines of equal pressure coupled in parallel by themselves.. If all the machines are coupled to main conductors, we may consider them one at a time, and take each dynamo as coupled to a system whose pressure and variations of pressure are independent of it. Suppose the effective pressure to be 2,000 volts, for example; we have to consider a pair of mains with 2,000 volts and we have to couple on a dynamo to add so many amperes to it. Such a machine must not be excited to give 2,000 volts on no load, being then thrown into circuit with full steam turned on immediately afterwards. It should be excited to give somewhere about half load with 2,000 volts at the terminals, and should then be thrown in. Steam can then be turned on, and the excitation raised to its normal value. The machine should be so designed that any excessive power that the engine may give shall not only not throw the machine out of step, but shall not increase the armature current to such an extent as to damage the insulation by excessive heating.

The power absorbed by a dynamo working on a parallel system is

$$P = \frac{B^2\,r}{2\,i^2} - \frac{A\,B\,r}{2\,i^2}\cos 2\,\pi\,n\,\tau + \frac{A\,B\,L}{2\,i^2}\sin 2\,\pi\,n\,\tau,$$

where A is the maximum station electromotive force—that is to say, the station pressure is $A \sin 2\,\pi\,n\,t$, — B is the maximum "impressed" electromotive force in the armature, r is the armature resistance, i the impedance of the machine, and τ the angle of lead. This equation is taken from a paper by Dr. Hopkinson. When the dynamo is doing its proper share—that is to say, under normal conditions—

$$B = I\,c,$$

where I is the impedance of the whole circuit when the machine is isolated, and working at full load on an external resistance, and c is the maximum value of the current. To find how much the driving power may increase for a small increase of current, we may differentiate with respect to c, and then find the value of L which makes the result a maximum.

$$c = \sqrt{\frac{A^2 + B^2 - 2\,A\,B\cos 2\,\pi\,n\,\tau}{i^2}}.$$

$$\text{Cos } 2\,\pi\,n\,\tau = \frac{A^2 + B^2 - i^2\,c^2}{2\,A\,B}.$$

So,

$$\frac{dP}{dc} = \frac{A\,B\,r}{2\,i^2}\cdot\frac{i^2\,c}{AB} + \frac{A\,B\,2\,\pi\,n\,L}{2\,i^2}\cdot\frac{d\sin 2\,\pi\,n\,\tau}{d\,2\,\pi\,n\,\tau}\cdot\frac{d\,2\,\pi\,n\,\tau}{d\cos 2\,\pi\,n\,\tau}\cdot\frac{d\cos 2\,\pi\,n\,\tau}{d\,c};$$

and in the case of a dynamo working on resistance, or on a station load when supplied with just its right share of power,

$$\cos 2\,\pi\,n\,\tau = \frac{A + r\,c}{B},$$

$$\text{and cosec } 2\,\pi\,n\,\tau = \frac{B}{L\,c}.$$

So,

$$\frac{d\,P}{d\,c} = \tfrac{1}{2}\,A + c\,r,$$

c being the maximum, not the effective, current. It will be observed that L has disappeared altogether.

This shows that for a very small increase of power the increase of current will be the same, whatever the self-induction of the machine may be. It would not matter if the machine had none. A machine with no self-induction would short-circuit the mains if the engine supplied too little power; in fact, at full load it would be giving its minimum possible output, and any attempt to diminish this would be disastrous.

Discussing the question of a very small increase is not exhaustive; an engine may supply a large proportion more than its share of power to one machine. For instance, suppose it supplies twice the normal power. Many engines could not give such an excessive power, but in others which have expansion gear controlled by a speed-governor, it is easy to get double power if the station is running at a slightly slower speed than that for which the governor is set. These matters are always made much clearer by taking practical examples and working them out. The great difficulty is to obtain accurate data. I should prefer to discuss such machines as those described in Mr. Mordey's paper read here a short time ago. Without wishing to say anything in disparagement of his excellent paper, I must point out that an account of experiments should contain full particulars of the machines on which the experiments were made. Such omissions are exceedingly common in electrical papers. Mr. Mordey has not given us the details of the field magnets, air space, armature coils or exciting coils; he has not even given us the currents in the different experiments. I have found similar omissions whenever I have tried to gain information from any of the numerous experiments which have been made on alternate machines in America. Mr.

---

[1] Abstract of a paper read before the London Institution of Electrical Engineers.

Mordey does, however, say that about half the drop in his machines is due to resistance, and half to self-induction. The machines give an output of 2,000 volts and 20 amperes, and when fully excited give 2,200 volts at no load. This would correspond to a self-induction of 0.05 henry.

Suppose, first, that the self-induction were such that $2 \pi n L = r$; on increasing the power supply, the effective current increases evenly, and when the power supplied to the machine is doubled, the effective current is only about 44 amperes. It is necessary, however, that the machine should stand decrease of load, as well as increase, without injury. Keeping the same self-induction, let us decrease the load to zero with the full excitation on. The current gradually diminishes to just below 15 amperes, and then increases to just over 20 again. These figures are extremely troublesome to work out from Dr. Hopkinson's equations, as the angle is so small that an error in about the sixth place of decimals will vitiate the results.

Many people prefer diagrams such as those used in mathematical books when dealing with harmonic variations. Mr. Blakesley has applied these diagrams to the discussion of alternate dynamos and motors, and Messrs. Kapp, Fleming, and others have applied them too. The chief drawback is that it is not always easy to draw such figures to scale. They are generally drawn with the values taken at random, to give ideas of the principles involved. So far as I know, no scale diagram of this sort has ever been published. In the case of the 40,000-watt machine such diagrams can be applied; but with 100,000 machines, which will probably be the standard size, the diagrams are almost illegible.

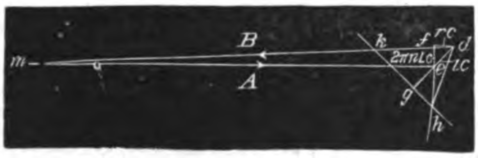

FIG. 1.

Fig. 1 is a diagram to scale. The lines are all rotating positively. The diagram is made as follows: The pressure in the mains, A, is drawn first. Instead of the maximum, it is simpler to draw the effective pressure—in this case 2,000 volts. From the end e, $2 \pi n L c$ is drawn at right angles to it to f; and then $r c$ from f, parallel to A; B is drawn to join the ends of A and $r c$, as shown. The lines are all pressures; but the instantaneous current is in step with the pressure $r c$ and with the pressure A, so that the power is proportional to B $r c \cos f d m$. I use the expression "in step" to mean co-phasally synchronised. Thus two machines may be running at the same speed without being in step; just as soldiers may take the same number of paces per minute without being in step.

To find the current at double load, produce $i c$ to g, so that

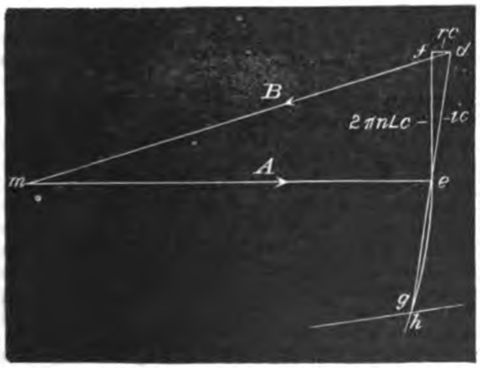

FIG. 2.

$d g = 2 i c$. Through g draw a straight line cutting B at k, at an angle, $g k d$, equal to the angle $d e f$. The line $g k$ is the locus of the end of the line representing the pressure spent over the resistance and self-induction of the armature with currents giving double load. It is unnecessary to go into the proof of this. With m as centre and A as radius, describe arc cutting $k g$ at h; join $d h$. Then the current at double load is to 20 amperes as $d h$ is to $d e$. In this case the double-load current is not much more than 40 amperes.

To find the current at half-load, bisect d e, and through point of bisection draw a straight line parallel to h k, and proceed as before. The no-load line, of course, passes through d.

Let us now assume the self-induction to be 0.05. The resulting diagram is shown in Fig. 2. The double-load current is almost exactly 40 amperes.

We thus find that according to the self-induction hypothesis the difficulty does not lie, as commonly supposed, in getting enough self-induction in the armature; the trouble is that there is generally too much. But in machines from 25,000 to 50,000 watts it is exceedingly difficult to make dynamos that will not run perfectly in parallel, so great is the permissible margin of self-induction. It must be carefully borne in mind that so far the armature has been supposed to have a constant coefficient of self-induction, and the pressures of current are assumed to vary harmonically.

The orthodox hypothesis thus tells us that with ordinary sizes of machines it is exceedingly difficult to design them so that they will not run in parallel. Either, therefore, all ordinary machines run perfectly in parallel, or the hypothesis is wrong.

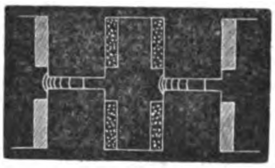

FIG. 3.

PARALLEL RUNNING ACCORDING TO ARMATURE REACTION THEORY.

Take the case of a machine like the Siemens, with coils passing between poles. If there is a continuous current in the armature, in some positions it will assist the field magnets, and in others it will to some extent weaken them, while in intermediate positions it has no effect on the magnets as a whole. In an alternate-current machine, though the armature current is alternating, relatively to the field magnets it is direct. If a series of instantaneous photographs of the armature current could be taken, each part of the air space would have its direct current.

If the pressure curve of such a machine were traced, and placed in the diagram of the poles, it would be as shown in Fig. 4. The positive direction of the current or pressure in the armature and field-magnet coils is shown by shading, the negative by dotting. If electricity flows in the armature when the sides of the coils are in the active fields, one side of the field between the poles is strengthened and the other weakened, as shown in Fig. 3. The field thus becomes stronger on one side. The curve of pressure thus gets displaced, as shown in Fig. 5.

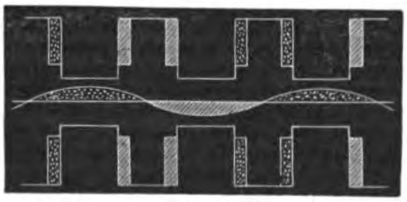

FIG. 4

It will be seen that each magnet is now exposed to the back induction due to the armature current. A circuit, a, taken round the field-magnet circuit is interlinked with the whole wave. The line integral is not changed if it is taken round any other circuit, so that the sides are the same distance apart as they are in a. A circuit taken as shown at b, however, includes only half a wave; so that from Fig. 5 both the cross and the back induction could be completely worked out.

The effect of the armature current, then, is first to make the current lag relatively to the position of the field magnets, and then to lessen the pressure as a whole. It thus resembles the effect of the insertion of artificial self-induction.

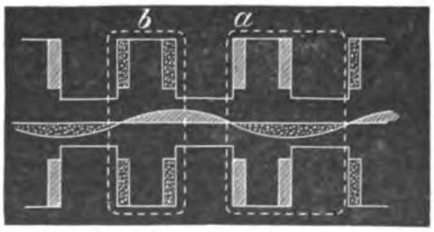

FIG. 5.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER 150 *Broadway, New York city.*

PLANT EFFICIENCY WITH HEDGEHOG TRANSFORMERS.

Mr. Swinburne's communication on plant efficiency of transformers, published in your issue of March 4, seems to me to require an answer. Neglecting so much of his communication as refers to personal matters, the first point raised by Mr. Swinburne is that the leakage current passing through his transformers when the secondary circuit is open is but one-third of the maximum value of the primary current at full load. In a communication received from Mr. Swinburne a few days after the publishing of my article, Mr. Swinburne states that the leakage current in his transformer is *about* 50 per cent. Allowing that this "*about*" 50 per cent. is correct, the comparative leakage currents in the open and closed types of transformers is approximately 10 to 1; that is to say, the leakage current in transformers of Mr. Swinburne's make is approximately ten times that ordinarily found in closed circuited transformers; and, as a consequence, some source of supply must be attained to furnish at all times ten (10) times as much current for the hedgehog transformer as is required for the closed circuit type. There should be no misunderstanding about this.

The second point raised by Mr. Swinburne that requires attention relates to the comparative hysteresis losses found in the closed circuit and hedgehog types. Mr. Swinburne says that at no load the loss in iron in hedgehog transformers capable of supplying 10,000 lights is 5,000 watts. He fails to state what size transformers are included in this estimate. If only this loss is attained when transformers of small capacity (from 20 to 40 light size) are used, then such transformers will not keep the potential upon the secondary circuit sufficiently constant for practical use. It is generally recognized in this country that the variation of potential upon the secondary circuit of small transformers must not exceed two (2) per cent.

This all goes to show that it is idle to compare the open and closed types of transformers, unless the comparison is made upon apparatus of similar size, and designed to work within fixed limits of regulation. The ingenious methods resorted to by Mr. Swinburne to make up the necessary current to supply his transformers, are, of course, a sort of solution of that difficulty. It is possible to arrange a motor-generator in a station to supply the false currents required, when no, or few, lights are burning. If I remember correctly, Mr. Swinburne has stated lately that he has been enabled to provide a condenser arrangement, such as suggested in his communication, which will be efficient and free from the liability of breaking down.

As to the remainder of Mr. Swinburne's communication, I am not aware that there is any monopoly on closed circuited transformers in this country, but Mr. Swinburne is probably not quite posted on the development of the closed circuited transformer. I have constructed a number of large transformers, which on test show an efficiency of 97.2 per cent., while the fall of potential upon the secondary circuit was but six-tenths of one (1) per cent. between full load and no load. These encouraging results lead me to believe that we shall still further advance in transformer development.

Mr. Swinburne closes with the remark that the advocates of closed circuited transformers should do him the justice to acknowledge that the value of their work is due to him because he read a paper in 1888, before the British Association on transformers. I am sure that all electrical engineers in the country will acknowledge gratefully, not only this communication of Mr. Swinburne's but all others that have emanated from his pen. We had generally supposed in this country that Prof. Ewing's work on hysteresis loss was fundamental, and so, before Mr. Swinburne's valuable paper appeared, numerous electricians in this country had made use of Prof. Ewing's work. It now appears that we should have waited until after the appearance of Mr. Swinburne's paper.

WILLIAM STANLEY, JR.

PITTSFIELD, MASS.

UNSUSPECTED ANTIQUITY OF WHEATSTONE AND HIS TELEPHONE.

Telephones are of greater antiquity, says the *Chicago Evening Post*, than is generally supposed. Wheatstone describes his "telephone" in 1721, and in 1854 Ch. Bourseul said: "It is certain that in a more or less distant future speech will be transmitted by electricity."

European Correspondence.

LONDON.

Signaling on Railways.—National Telephone Co.

CALLING at Basinghall street a few days ago, I was shown Pere's electric railway signaling system, the inventors of which claim that it is calculated to afford immunity from almost every ordinary form of railway accident. I was supplied with the following statement which amply describes the apparatus. It consists of three conductors, one of which lies between the rails, and the other two on either side of it, on each track, the two lateral conductors being either within or outside the rails. The central conductor is continuous, while the lateral ones are interrupted, the interruption on one side of the line being opposite the central portion of the other lateral conductor, and the lengths of the conductors, which are calculated to form blocks for signaling purposes, being such as the amount and complexity of the traffic may require. The conductors are bars of rigid metal, copper being used in the model; but it is said that soft iron will answer every purpose in actual traffic. They are kept in electrical contact with the engine, or, if desired, with any portion of the rolling stock, by metallic brushes descending from the latter and resting upon the conductors but so arranged and placed as to be subjected to the minimum of wear from friction. The forward end of each lateral conductor, at each point of interruption, is connected by an underground wire with the hinder end of the conductor on the other side at the next interruption. The electric force is supplied by a battery carried on each engine, and, as only a small amount of power is required, the inventors speak of ten Leclanché elements as being sufficient for the purpose. It would be impossible, without the aid of diagrams, to convey a clear notion of the manner in which the actual and possible circuits are arranged; but the general effect is that each engine is able to ring a call-bell at the station in front of it or at the one behind it, or at both, and, having thus obtained attention, is able to open telephonic communication with them. When a traveling engine receives a current from another, this may be caused either to ring a bell or to release a weight the fall of which may put on a brake, so that any alarm given to a driver may either inform him of some danger or may automatically arrest his course. If trains are running in opposite directions on the same line of rails, and equally if one train is overtaking another on the same line, or if approaching a stationary train on the same line, as happened at the recent accident near Taunton, so soon as they are within a distance of each other, which is governed by the distance apart of the interruptions on the lateral conductors, a bell is rung on each engine, or, as just said, things may be so arranged that a brake is applied. In either case, the two drivers at once obtain the power of telephonic communication with each other. The rolling stock may be fitted with brushes which do not usually touch the conductors, but which are suffered to fall upon them by any severance of the train: and in this way the presence of a detached carriage may be instantly made known not only to approaching trains, but also at both the adjacent stations. Approaching trains could be at once warned by plate layers of the presence of any obstacle on the line; and would be warned automatically if the obstacle were a conductor of electricity, so that it would serve, when lying across the conductors, to short circuit the current. Plate layers would also be provided with portable telephones, which they could connect at any point for the purpose of communicating the intelligence of any accident or impediment. A bell might be rung upon the engine, or a brake applied, either when approaching points which were wrongly set or on running into a dead siding. Drivers might be prevented from permitting undue delay in the application of the brake on approaching a station or at any other point on the line, and a bell might be rung continuously at every level crossing when a train had come within a certain distance of it, and until it had passed by. It is said on the part of the inventors that the fitting the apparatus to the railway, exclusive of its application to the rolling stock, would cost only about £150 a mile, and that the insulation of the conductors will be easily maintained and easily tested. The system, if successfully in operation, would greatly facilitate the conveyance of large bodies of troops by railway, in consequence of permitting a free communication between successive trains, and on this account I understand the German military authorities are about to test its applicability in actual working.

A meeting of the Western Counties' shareholders is to be held next week for the purpose of passing a resolution to sell the concern to the National Company. The Western Company is a branch of the larger company worked by license. Such was the enterprise and zeal of the local managers that the offspring bid fair to run the parent a hard race. As an indication however that the administration of the National Company does not meet the approval of all the subscribers, it may be mentioned that at a private meeting of the Border subscribers consisting of about 200, it was unanimously agreed to give the company notice to remove telephones and poles. I believe that the cause of the disagreement is the refusal of the National Company to lower their charges.

LONDON, March 11, 1891.

Literature.

Sixth Annual Report of the Board of Gas and Electric Light Commissioners of the Commonwealth of Massachusetts. January, 1891. (Pub. Doc. No. 35.) Boston, 1891.

Twenty Second Annual Report of the Board of Railroad Commissioners, January, 1891. (Pub. Doc. No. 14.) Boston, 1891.

The venerable commonwealth of Massachusetts has always adhered to the highly commendable practice, which might be followed with obvious advantage by many of her sister states, of appointing as members of her board of commissioners of public works, reputable citizens of capacity and intelligence, rather than rumsellers and ward politicians; and, as a consequence, many of the reports which issue from her state printing office have a positive and practical value, and abundantly repay critical examination. In this respect, it is not too much to say that the Massachusetts public documents need not, as a rule, fear comparison with the parliamentary bluebooks of our transatlantic cousins, which, by the way, is no inconsiderable praise.

In a general review of the condition and prospects of the illuminating companies, both gas and electric, the commissioners make the following observation:

> The amount of capital stock is usually of vital consequence to the consumers and patrons of a company. It should be kept at the lowest practicable point, as the best guarantee for cheap light, as well as for reasonable dividends. Some of the companies, managed by men of a speculative turn of mind, manifest a desire that every expenditure for construction or improvement, or rise in the market value of plants, shall be represented by interest-bearing dividend scrip, or by new shares of stock, on which it is proposed to pay the usual dividends, at least until the stock is palmed upon innocent buyers. To avoid disappointment and loss by such stockholders, whenever the law shall be applied regulating the price of light, which intelligent consumers ask to have fixed on the basis of actual and necessary cost and reasonable dividends, it is suggested that the issue of such scrip be prohibited, and that the prior assent of the board to a new issue of stock be prohibited by statute.

In view of frequent inquiries received by the board in reference to the vexed question of the actual candle-power of arc lights, authority is asked to employ an expert at discretion to make tests when necessary. The board, although authorized by statute to do so, has not deemed it expedient to attempt to regulate either the prices or conditions of the electric light supply, except in one instance. The Boston Edison Company objected to supplying at night a certain block of buildings equipped with lamps and fittings of a different make, and which depended upon its own plant for its current during the day. Under the authority of the statute of 1886, an order was made in this case by the board directing the Edison Company to supply the petitioners with current, which appears to have been complied with, without further objection.

Five cases of personal injury from electric currents were reported during the year, three of which were fatal. They were all caused by a 1,000-volt alternating current, and occurred in each case by the careless handling of wires. The statistics given in the report are interesting and instructive. The increase in the number of local companies during the year past, as might have been expected, is not great, but the aggregate capacity of the existing plants is being rapidly enlarged. There are now 73 chartered gas companies operating in the state, of which 28 are also supplying electricity. The number of electric companies is 111, an increase of 11 from last year. The receipts of the gas companies, notwithstanding the competition of the electric light, continue to show a steady increase in the sales by meter, though, as was the case the preceding year, the receipts from street lighting show a steady diminution, the figures being in round numbers, $327,000, as against $353,000 in 1889.

The aggregate liabilities of the electric companies as compiled from the figures given in the report, together with some other statistics of interest for the year ending June 30, 1890, are given below:

Aggregate capital of the 61 electric companies (not including gas companies supplying electricity)	$6,452,025.00
Total bonded and floating debt	2,102,944.80
Aggregate liabilities	$8,554,969.80
Receipts:	
For light and power	$1,908,394.00
From other sources	12,308.05
Total receipts	$1,920,702.05
Expenses:	
For manufacture	$ 752,881.18
For distribution	281,046.33
For office expenses and management	116,350.92
For taxes	67,620.91
For miscellaneous	122,965.26
	$1,340,814.60
Leaving a balance of	579,887.45
Deduct net earnings of electric departments of gas companies	110,871.40
Net earnings of electric companies	$469,016.05

	1889.	1890.
Total number of dynamos	368	578
Motors:		
On arc circuits	111	100
Incandescent circuits	379	578
Power circuits	48	128
Total motors	538	806
Commercial incandescent lamps	72,419	118,521

Of the 100 electric companies reporting, 22 have paid dividends during the year ending June 30, 1890, varying from 2½ per cent. by the Boston Edison Co. to 10 per cent. by one of the two companies in Pittsfield (a very small company by the way). The average rate of dividend paid is 4.86 per cent. The total amount paid in dividends during the year was $154,708, which is equal to only about 2.4 per cent. on the aggregate capital stock of all the companies in the state. This total net earnings of all the electric companies as reported, is equal to 5.48 per cent. on their aggregate liabilities.

Upon the fairly probable assumption that actual number of lamp hours is 12 per cent. of the maximum, the light given by the 118,521 commercial incandescent lamps during the year would be equivalent in round numbers to 628,000,000 feet of gas. This is only about three times as much gas as was made by the Lowell company alone during the year, and shows conclusively that the field of domestic electric lighting in Massachusetts is even yet far from being fully occupied.

Much other material of value might be gathered from this report if one had the time and patience to wade through the wilderness of figures, and foot up the tables given. In commenting upon the report of last year, we found occasion to criticise the omission of these summaries; a repetition of which negligence, in an official report of this character, is little less than unpardonable.

No such criticism can be made upon the report of the railroad commissioners, which, as is always the case, is a model of what an official report should be. All necessary information is given in a concise and convenient form, while the mass of useless verbiage too often forming the staple of such publications is conspicuous by its absence.

In the report of last year, attention was directed by the board to the necessity of regulating the speed of electric cars, and of equipping them with more efficient brakes. This warning has been justified by the increased number of accidents which are reported as having occurred during the past year. The result of a series of brake-tests, made under the direction of the board, resulted in the enactment by the legislature of a statute requiring street railway companies operating with other than horse-power, to equip their cars with such guards or fenders as the board may direct. The whole subject was then exhaustively investigated, and the results of the experiments made are given in an appendix of 38 pages, with numerous illustrations, containing the report of Professor G. F. Swain, the bridge engineer of the board. The result of his investigations was to demonstrate that it is not possible to devise an efficient form of fender applicable to four wheeled cars, when traveling at a high rate of speed, say seven miles per hour or over, on account of the vertical oscillation or "pitching" of the car. With double-truck cars, no especial difficulty exists. The statistics of the West End Company, of Boston, show that when computed on a basis of mileage, there have been twice as many accidents from electric as from horse cars.

The statistics of the electric railways of Massachusetts for the year ending September 30, 1890, are briefly as follows:—

Number of companies having electric lines in operation	17
Overhead trolley system, total miles	157.77
Storage battery system, total miles	3.09
Total miles electric railway in state	160.86
Number of companies having electric lines under construction	7
Overhead trolley system, total miles	28.45
Storage battery system, total miles	6

The maximum average running speed of the Boston and Revere and of the West End lines, when unobstructed by horse cars on the same track, is given as 12 miles per hour.

The report shows that the total number of trespassers on the tracks of the steam railroads of the state who were killed or injured during the year was 199, but it is probable that the newspapers have devoted more space to the reports of the three unfortunates who were killed by electric currents than to the whole number killed by the railroads.

The following figures relating to the operations of the West End Company, of Boston, are of interest:—

Receipts from passengers	$5,678,390.07
Receipts from other sources	101,592.50
Total receipts	5,780,082.57
Total expenses of all kinds	4,468,368.75
Percentage expenses to earnings	.77
Number of cars	2,031
Total length of road including sidings (miles)	239.45
Total miles run	17,665,860
Total number of passengers carried	114,853,081
Total number of employés	4,148
Gross income per mile run	$0.3272
Net income per mile run	$0.0742

Full returns are given of the results of operations of all the street railways, but as none of the exclusively electric lines have been running long enough to enable deductions of value to be made from an analysis of the returns, it is scarcely worth while to undertake it. The most important of the street systems are still in process of changing from horse or steam to electric power, which renders it difficult to get at trustworthy figures from their present returns. In future years, however, the Massachusetts reports cannot fail to be, in this respect, of the greatest value.

Reports of Companies.

AMERICAN BELL TELEPHONE CO.

The annual meeting of the Bell Telephone Company occurs early this week. If, as expected, the earnings of the company show the usual annual gains over the previous year, the report for 1890 will show net earnings of about $2,900,000, or about 23.2 per cent. on $12,500,000 capital stock.

The instrument output of the Bell Telephone Company for the month ending March 20, and for the three months of the company's fiscal year, is reported to-day, in comparison with last year, as below:

Month ending March 20.	1891.	1890.	Inc.
Gross	5,717	5,179	538
Returned	3,167	1,648	1,519
Net	2,550	3,531	†981
Since Dec. 21.	1891.	1890	Inc.
Gross	15.954	12,819	3,135
Returned	9,561	6,150	3,411
Net	6,393	6,669	†276

†Decrease.

COMMERCIAL CABLE COMPANY.

The following officers have been elected for the ensuing year by the new board of directors of the Commercial Cable Co.: J. W. Mackay, president; G. G. Ward, C. R. Hosmer and A. B. Chandler, vice president; E. C. Platt, treasurer and J. O. Stevens, secretary.

THE ELECTRIC MANUFACTURING AND GAS ENGINE CO.

The above company has been formed at Greenbush, N. Y., with a capital stock of $75,000. Its object is to manufacture gas and other engines and accessories thereto, and electrical apparatus of various kinds. The trustees are: E. N. McKinney, of Albany; G. H. Ennis, of Troy; R. J. Pratt and J. H. Pratt, of East Greenbush, and A. Rollanson, of England.

STOCKS AND BONDS.

HANNIBAL, MO., refuses to sell her 5 per cent. 50-year electric light bonds for less than par, and the town remains insufficiently lighted.

BOSTON, MASS.—The American Bell Telephone Company holds its annual meeting in room 21 of its new building at No. 125 Milk street, March 31, the books being closed March 27, to reopen April 11.

BROOKLYN, N. Y.—The stockholders of the Atlantic Avenue Railroad, of Brooklyn, have voted to increase the capital stock from $1,000,000 to $2,000,000. The money is to be used in equipping the roads with electricity as a motive power as soon as the franchise is granted. All of the Brooklyn surface roads are preparing to substitute electricity for horse power.

TOLEDO, O.—The Toledo Electric Railway has added $200,000 to its capital stock.

WINTHROP, MINN.—The city of Winthrop has voted to issue bonds to the amount of $5,000 to be expended in waterworks and an electric plant.

ATTLEBOROUGH, MASS —The sale of the Attleborough street railway has been negotiated, it is understood, with private parties. This road has a capital stock of $60,000, and a debt of $50,000 5 per cent. bonds. It is some six miles long, runs to North Attleborough and Wrentham; is, to an extent, a competitor of the steam railroad; is operated by electricity, and is said to earn 10 per cent. on the stock and almost as much more surplus per year.

BOSTON, MASS.—The Erie Telephone directors have under consideration a proposition to sell all or a part of the company's 70 per cent. interest in the Southwestern Telegraph and Telephone Company for $700,000, from a Texas syndicate.

LAWRENCE, MASS.—The Merrimack Valley Street Railway Company have received permission to increase their capital stock from $80,000 to $250,000. The petition was presented in order to secure money for equipping the road with electricity. Plans have been drawn for a power station, and now that the money is ready work upon the electric road will soon be begun. The North Andover and Methuen line will be made ready first for electric cars and then the line to Andover will be built and equipped.

BUTTE, MONT.—One of the most important sales recorded in Butte for some time past is that of the Metropolitan Street Electric Railway to Eastern capitalists. The price paid was $150,000. It is reported that the new company have also been negotiating for the purchase of the Butte Street Railway Company's lines and rolling stock, with a view of consolidating the two lines.

ELECTIONS.

KANSAS CITY, MO.—At a recent meeting of the Gill-Alexander Electric Lock Company, the following officers were elected: Robert Gilham, president; W. W. Alexander, vice-president; M. C. Gilham, secretary and treasurer. The company has a capital stock of $800,000. Among the prominent local men who are stockholders in the company are: Ed. F. Swift, R. R. Conklin, S. M. Jarvis, H. P. Churchill, J. W. and F. K. Hoover and James Lillis.

NEW YORK CITY.—The United Telegram Company at a recent meeting added to the board of directors Messrs. Albert B. Chandler and John W. Mackay, Jr. Mr. Chandler also was elected president of the company. He is president of the Postal Telegraph Cable Company and vice-president of the New York Quotation Company, the last-named being owned and operated by the New York Stock Exchange.

DUNKIRK, N. Y.—The directors of the Dunkirk and Fredonia Rapid Transit Company have elected the following officers: President, Frank E. Shaw; vice-president, Byron Rathbun; secretary, Samuel J. Gifford; treasurer, W. T. Colman.

WAYNESBORO, PA.—The directors of the Waynesboro Electric Light Co. have elected the following officers: President, Daniel Hoover; secretary, D. H. Geiser; superintendent, J. F. Geiser. There is about $11,000 of the stock subscribed, and the balance of the $15,000 is going rapidly. There are some 80 shareholders in all.

YOUNGSTOWN, O.—The stockholders of the Youngstown Electric Street Railway have elected the following board of directors: James Parmelee, G. E. Herrick, Myron T. Herrick, W. H. Lawrence, H. M. Garlick, William Cornelius and Hal K. Taylor. The board organized and elected James Parmelee, of Cleveland, president, William Cornelius of this city vice-president, and Hal K. Taylor, secretary.

HAGERSTOWN, MD.—Daniel Hoover has resigned the presidency of the Waynesboro Electric Light Company and E. Elden has been elected to succeed him.

DIVIDENDS.

BOSTON, MASS.—The Edison Electric Illuminating Company, of Boston, has declared a semi-annual cash dividend of 3 per cent., payable April 1.

PROVIDENCE, R. I.—The Narragansett Electric Lighting Co. has declared a dividend of $1 per share, payable April 1.

THE EDISON GENERAL ELECTRIC Co. has declared its sixth quarterly dividend of 2 per cent.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of March 28, 1891, from New York, Boston and Washington; Pittsburgh, March 27.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 24, 1891.

Alarms and Signals :—

Fire-Alarm Signal Box, W. F. Singer, 448,684. Filed March 11, 1889

Provides visual and audible signals, and includes means for conveying the current around a break caused by any accident. In addition to a main circuit an auxiliary is provided ; a relay in each signal box automatically cuts in the auxiliary circuit upon rupture of the main circuit.

Electric Time Alarm, J. J. Gallagher, 448,712. Filed Nov. 28, 1890.

An electro-magnetic alarm clock.

The following three patents were omitted from our list of patents issued March 17.

Signal Box, J. C. Wilson, 448,398. Filed May 17, 1887.

Comprises an endless band and a series of groups of signaling surfaces, each group arranged transversely thereon, and a contact pen to operate with any group of signaling surfaces.

Signal Box, J. C. Wilson, 448,399. Filed May 17, 1887.

Specially applicable for police signaling. The signaling surfaces are arranged upon a drum, each running longitudinally from end to end, and are traversed by a contact arm.

Signal Box, J. C. Wilson, 448,400.' Filed May 17, 1887.

Employs a rotatable contact pen with a series of signaling surfaces arranged on a carrier movable in a direction parallel with the axis of rotation of the contact pen to present one or another signaling surface.

Clocks :—

Independent Electric Clock, W. S. Scales, 448,998. Filed July 19, 1890.

Contains a regulating member for actuating the driving mechanism in case the armature of the electro-magnet fails.

Secondary Electric Clock, W. S. Scales, 448,999. Filed Oct. 20, 1890.

Mechanism and devices similar to those of No. 448,998 above, applied to a secondary clock.

Conductors, Conduits and Insulators :—

Water-Proof Combined Coupling and Cut-Out for Electric Circuits, F. Shlaudeman, 448,679. Filed Nov. 3, 1890.

Applicable to the use of interior conduits and shown applied to an incandescent lamp circuit.

Connector for Electric Wires, F. Shlaudeman, 448,680. Filed Nov. 3, 1890.

A conduit joint adapted to making a firm contact between conductors end to end.

Insulator for Electrical Conductors for Mines, F. A. Pocock, 448,838. Filed June 26, 1890.

Applicable to conduits for electrical conductors in the gangways of mines; employs flexible sheets which close an open side or slot of the conduit and permit the passage of a trolley or connector arm.

Electric Insulator, G. H. Graham and T. Gannane, 448,956. Filed Aug. 2, 1890.

An insulator of glass or similar material adapted to be screwed on a pin in the usual manner, and having a transverse groove in its upper end for receiving the wire ; it is provided on the outside with a threaded portion for receiving a ring ; the wire is held in place by loops from the ring.

Distribution :—

Electric Converter, M. G. Farmer, 448,614. Filed Oct. 11, 1890.

Employs laminated cores without the use of insulating material, in place of which very thin sheets of non-magnetic metal are substituted. Also divides the core elements transversely so that the core may be laminated not only in planes parallel to its axis but also in planes at right angles thereto.

Dynamos and Motors :—

Dynamo-Electric Machine, S. E. Nutting, 448,666. Filed May 13, 1890.

Designed to be capable of producing either a direct or an alternating current. One form described consists of two sets of field magnets, each having a hub and four cores projecting radially at right angles, and in the same plane, and having polar extensions from the outer ends of the cores of one set at right angles with their plane and connecting with the outer ends of the cores of the other set ; the armature is adapted to rotate within a circle partly enclosed by the polar extensions. In the armature core a series of thin strips of magnetic material is centrally mounted on the shaft, and a further series of such strips are centrally mounted on the shaft at right angles to and alternating with the first series of strips.

Electric Contact Device, F. A. Perret, 448,669. Filed June 28, 1890.

An improvement in carbon brushes for dynamos and motors adapted to provide greater surface contact between the brush and commutator. The brush holder is provided with a number of cylindrical chambers in which are loosely placed pencils of carbon which are held independently against the surface of the commutator by springs.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, C. J. Hirlimann, 448,798. Filed Nov. 26, 1890.

The porous vessel is made of moulded carbon and filled with manganese or other depolarizing agent, and has a concave bottom provided with perforations.

Clamp for Electric Battery Zincs, J. H. Leakin, 448,847. Filed Dec. 24, 1890.

A clamp designed to permit the removal of the zinc element without disturbing the connecting wire.

Electrolyte for Galvanic Batteries, J. J. Collins, 448,936. Filed Sept. 30, 1890.

Consists of an alkali, bichromate of potash or bichromate of soda, bluestone, an exciting acid, sulphur, and sulphate of mercury.

Lamps and Appurtenances :—

Cover for Incandescent Lamps, E. T. Mueller, 448,741. Filed Oct. 18, 1889.

A cover or shade formed of two similar halves with a connecting spring and catch.

Electric Lighting, R. M. Hunter, 448,782. Filed Dec. 30, 1890.

Employs, around an incandescent lamp connected in series, a shunt circuit, including a heating resistance enclosed in a receptacle which also contains an expansible substance adapted to be heated by an excessive current caused by breakage of the lamp.

Filament for Incandescent Electric Lamps, G. Erlwein and F. G. A. Heller, 448,914. Filed July 22, 1890.

A carbon core is provided with a hardly-fusible coating, consisting, essentially, of a compound of carbon and manganese.

Filament for Incandescent Electric Lamps, G. Erlwein, 448,915. Filed July 22, 1890.

Carbon filament is coated with nitride of silicon.

Filament for Incandescent Electric Lamps, G. Erlwein, 448,916. Filed Oct. 25, 1890.

Carbon filament is provided with a coating consisting of phosphorus, combined with a hardly-fusible metal ; as phosphorus and iron.

Filament for Incandescent Electric Lamps, F. G. A. Heller, 448,920. Filed July 22, 1890.

Consists of a small carbon rod with a covering of metallic chromium deposited thereon.

Electric Lighting System, E. H. Johnson, 449,041. Filed Jan. 10, 1884.

Devices and arrangements of circuits adapted to utilize electric lamps for displays of various kinds, as for ornamental and advertising purposes.

Measurement :—

Meter for Alternating Electric Currents, O. B. Shallenberger, 448,676. Filed March 13, 1890.

So constructed that the armature will require a certain value of current to set it in operation by reason of a dead-point formed in the armature. Such currents as may leak through the circuit when no work is being done will be insufficient to overcome the dead-point ; but the current required to operate lamps or other translating devices will overcome the dead-point and cause the meter to record.

Meter for Alternating Electric Currents, O. B. Shallenberger, 448,677. Filed March 13, 1890.

Designed so that it will commence to operate only when the current through the circuit in which it is connected exceeds the leakage of the circuit or of the converters. A short circuiting device, applied to the primary inducing coil, is automatically operated by the currents traversing the circuit.

Electrical Indicator, C. Wirt, 448,792. Filed May 2, 1887.

Improvements on the indicator patented to the same inventor July 20, 1886, No. 345,755. The improvements relate to the arrangement and construction of the adjustable resistance employed. The improved rheostat includes a turning drum having wire coils wound longitudinally upon it, bared for a portion of their length, transverse windings at the side of the bared portion to hold the coils in place, and a stationary contact bearing on the bared section of the coil.

Electric Meter, E. Thomson, 448,894. Filed Sept. 26, 1890.

Relates to meters for either continuous or alternating currents and to the class of meters known as "motor-meters." The commutator of the motor has both its moving and stationary conducting surfaces made of pure silver ; the commutator is made of the smallest practicable diameter.

Method of Measuring Alternating Electric Currents, O. B. Shallenberger, 449,001. Filed Dec. 26, 1888.

Claim 1 includes the method of measuring the currents consumed in doing useful work which consists in employing the leakage current of the circuit to overcome the inertia of the meter and in operating the meter by the current flowing in excess of such leakage current.

Meter for Alternating Electric Currents, O. B. Shallenberger, 449,002. Filed March 3, 1890.

Employs a thermostatic brake connected in circuit with the meter and operated by currents traversing it to release the meter when such currents exceed a predetermined value, thus preventing the operation of the meter by leakage currents when no work is being done.

Meter for Alternating Electric Currents. O. B. Shallenberger, 449,003. Filed March 13, 1890.

Claim 1 covers an arresting device for normally preventing the operation of the electric motor of the meter, and a releasing device brought into action by the currents traversing the motor when they exceed a predetermined value.

Medical and Surgical :—

Electric Belt, W. C. Fuller, 448,953. Filed Jan. 21, 1891.

A battery of a number of flat cells enclosed within a flexible casing adapted to be worn around the body.

Miscellaneous :—

Electric Switch, D. B. Turner, 448,698. Filed June 18, 1890.

Two elbow crank-levers have suitable contacts for their long ends, a reciprocating piece is connected with their short ends, and a lock has a movable part controlling the reciprocating piece.

Electric Heater for Dental Vulcanizers, J. O'Meara, 448,743. Filed Oct. 22, 1890.

In a dental vulcanizer having a steam generator, with a surrounding incombustible jacket, an electric heating coil is placed around the jacket.

Electric Heating Apparatus, M. W. Dewey, 448,879. Filed Jan. 20, 1890.

Employs a fibrous refractory material enveloping or covering the electric conductors and in continuous contact with them.

Electrical Protector, I. N Miller, 448,980. Filed Oct. 28, 1890.

A protector against excessive currents, in which a heat coil having an expansive core is employed to release, through the expansion at its core under the influence of an excessive current, the short arm of a lever for opening the circuit.

Electrical Heater, J. V. Capek, 449,035. Filed July 21, 1890.

For cooking. Details of construction and arrangement for applying electric heating to ovens and other cooking utensils.

Electrical Heater, J. V. Capek, 449,036. Filed July 21, 1890.

For cooking ; similar in purpose to No. 449,035 above.

Electric Rock-Drill, W. M. Schlesinger, 449,090. Filed Nov. 17, 1888.

Application of the electric motor to a rock-drilling machine ; includes special devices for disengaging the feeding mechanism from the drill-rod to admit of a quick return of the drill-rod independently of the feed mechanism.

Railways and Appliances :—

Electric Railway, R. M. Hunter, 448,653. Filed March 24, 1887.

Adapted to conduit systems employing sectional conductors and operating upon a series system.

Speed-Regulator for Electric Motors, S. H. Short, 448,681. Filed Oct. 10, 1890.

Particularly applicable to railway car motors. A speed branch in the form of a shunt on the field, with suitable means for cutting in and out, is used in connection with a series field, and in addition to an adjustable rheostat ; the cutting-in of the speed branch causes a fall of counter electromotive force at the armature brushes.

Adjustable Rheostat, S. H. Short, 448,682. Filed Nov. 15, 1890.

For motor cars. Consists in a number of insulating receptacles filled, between conducting end plates, with subdivided conducting or semi-conducting material, carbon powder, for example, and provided with contacts, connections and a traveling contact.

Support for Electric Line-Wires, H. C. Wirt, 448,703. Filed March 17, 1890.

A support and insulator adapted for suspending trolley wires from transverse supporting wires.

Overhead Crossing Appliance for Electric Railways, I. H. Farnham, 448,711. Filed Nov. 20, 1889.

A device for use at electric railway crossings where the overhead conductors are upon different levels; provides means for conducting the trolley traversing the upper conductor around the lower conductor without interrupting electrical connection between the trolley and the upper conductor.

Railway-Circuit for Signaling and Controlling Trains, F. E. Kinsman, 448,751. Filed June 11, 1890.

Claim 1 follows:

In an apparatus for controlling the movement of railway trains the combination, with a controlling magnet in a normally charged circuit, and means for interrupting such charged circuit to set the apparatus in "danger" condition, of a supplemental magnet or magnet coil for keeping the apparatus in "danger" condition, and a circuit therefor independent of that used in setting the apparatus, said circuit being through the rails and car wheels and axles of a section of road upon which the train moves, while the apparatus requires to remain in "danger" condition.

Electric Railway. T. A. Edison, 448,778. Filed Aug. 7, 1882.

Claim 1 follows:

In an electric railway, two main line conductors, in combination with a source of electrical energy therefor, and two branch line conductors connected to the main line conductors in permanent multiple arc connection.

Trolley for Electric Railways, R. Eickemeyer, 448,831. Filed July 19, 1890.

Adapted to a double trolley system employing two line wires one above the other; the grooved trolley wheels on each wire are connected together by a complex link having a central hinged joint, coupled to the two trolleys by other hinged joints, the axes of the wheels in both trolleys being parallel with the axes of the several hinged joints.

Protecting Motor Mechanism of Electric Cars, S. H. Short, 448,840. Filed Nov. 15, 1890.

Provides, with a car having an electric motor mounted on a driving axle and extending below the same, a protecting pan below the motor and curved in the direction of the travel of the car.

Electric Signaling Apparatus for Railways, E. D. Graff, 448,856. Filed Sept. 29, 1890.

Adapted to the "block system." Relates to means for signaling between two approaching trains on the same track; for signaling an approaching train when the train preceding it has stopped or for any reason has failed to pass out of a prescribed block; and to means by which the signaling devices are regulated or controlled so as to give notice to the engineers of approaching trains and to the engineer of a train which may come within a block or section of a track before a preceding train has passed out.

Lamp for Electric Railway Cars, C. G. Smith, 448,865. Filed Feb. 26, 1890.

Frame and reflector for electric or other lamps for attachment to the ceiling of a car.

Electric Street Car Driving-Gear, C. M. Conradson, 448,910. Filed Dec. 3, 1890.

Armature or motors journaled directly upon an inclined shaft carrying worm gear at each end meshing with gear wheels upon the axles of a car.

Locomotive Engine, R. Peacock & H. L. Lange, 448,927. Filed Sept. 20, 1890.

Method of connecting electric motors to the driving axles. Employs cranks and diagonally disposed connecting rods between the motor shaft or shafts and the axle or axles of the car, together with suitable guides.

Telegraphs:—

Telegraph, T. A. Edison, 448,779. Filed July 19, 1886.

Combines with two or more telegraph lines, each having ordinary Morse sets and induction sets, of one or more induction connections between such lines and one or more retarding or damming magnets to divert the inducting signals from portions of such lines. A "duplex" or "diplex," combining on one circuit ordinary Morse working and induction working.

Telephone Transmitter, T. Oeyan, 448,726. Filed Oct. 25, 1890.

Relates to the class of transmitters in which loose or granulated carbon is used for one of the electrodes, and consists in means for loosening the granulated carbon after it has become too compact from use without disarranging the apparatus or taking it apart.

Obituary.

MR. T. A. GAMEWELL.

Mr. T. A. Gamewell, one of the pioneers in the construction of telephone lines in the West, died at his residence at Denver, Col., on March 16th, of cancer of the stomach. Mr. Gamewell was superintendent of the construction department of the Colorado Telephone Company, and constructed the telephone line to Leadville over Mosquito Pass, a most difficult undertaking.

Appointments, Etc.

DANIEL E. SMITH, manager of the Portsmouth, Dover and Exeter (N. H.) Telephone Exchanges, has resigned his position and the vacancy has been filled by the appointment of William Todd, who has been located at Amesbury. He will have charge of Exeter and Dover. Edward Drew will have charge of the Portsmouth and York exchanges.

MR. WALTER N. SPERRY has been appointed general manager of the Birmingham division of the New England Telephone Company in addition to the Waterbury division. His assistant will be R. H. Gray, of Waterbury.

MR. T. J. EVANS has resumed the management of the Ottawa, Ill., Electric Street Railway Company and its affairs, which he turned over to the Thomson-Houston Company in Chicago, June 1, last.

Legal Notes.

KANSAS CITY, MO.—The Gill-Alexander Electric Lock Company have voted to retain Warner, Dean & Hagerman and Gates & Wallace to defend the injunction suit brought against it by the Secret Service and Combination Electric Lock Company, of New York city, for the possession of a one-half interest in the Gill patent.

UNITED LINES TELEGRAPH CO.—Henry Winthrop Gray has been appointed receiver of the United Lines Telegraph Co. by Judge Ingraham, of the New York Superior Court, in a foreclosure suit brought by the Farmers' Loan and Trust Co. His bond is fixed at $25,000.

INDIANAPOLIS, IND.—The Brush Electric Light Company have made application in the U. S. Court for an order restraining the Pettis Dry Goods Company from using the double carbon light.

Society and Club Notes.

NEW YORK ELECTRICAL SOCIETY.

The above society held a very large and successful meeting at the Electric Club, on March 27, when Mr. Joseph Wetzler gave an illustrated address on "The Electrical Progress of 1890." Mr. Wetzler had numerous models and drawings, and was assisted by many of the inventors, who came forward and described their own work. These gentlemen were: P. B. Delany, F. Jarvis Patten, Nikola Tesla, J. J. Carty, G. W. Walker, W. J. Jenks, W. E. Geyer, J. C. Chamberlain and Park Benjamin, who described Lieut. B. A. Fiske's range and position finders.

THE MILLIKEN POLES.

Messrs Milliken Bros., New York, report a large demand for their patent street railway and electric light poles, which they are now furnishing to almost every section of the country, including Canada. The large and increasing demand for these poles shows beyond doubt their superiority for the work for which they are designed. They have their large shops now completed with special machinery for turning out this class of work, and are able to fill orders promptly, either from stock on hand or at short notice. Among the recent orders which they have secured are the iron poles to be used for all the street railway work at Pittsfield, Mass. The street on which these poles are to be used is unusually wide, and consequently the strain on the poles is very great, and after a careful study the road found it to its advantage to use the Milliken pole. This firm has now out a very handsomely illustrated catalogue showing the different forms of poles which they make and their advantages, notice of which is given in another column. Parties desiring information on the use of poles for street railway or electric light work should write to the concern for information.

ISKE'S AUTOMATIC FIRE ALARM.

In THE ELECTRICAL ENGINEER, of March 11, appeared an illustrated article descriptive of the Iske automatic fire alarm, manufactured by Stoner, Myers & Company, of Lancaster, Pa. Since the appearance of this article the manufacturers have given a public test in Lancaster, under the direction of the mayor of that city. A match was applied to some "excelsior" in a building, with a view to reproducing the actual conditions of a fire, and within 15 seconds from the time the match was applied the automatic danger signal was given. The following item from the *Lancaster Daily Intelligencer*, of March 17, gives a terse and very satisfactory account of the test: "This morning a public trial of an automatic fire alarm which has been patented by Anthony Iske, was made by Boardman & Schaum, agents for the machine, at the works of Stoner, Myers & Co., on North Cherry street. Quite a crowd, including Mayor Clark, Chief Engineer Vondersmith, Chief of Police Borger, and a number of prominent business men witnessed the exhibition, which was a success in every way. The alarm is a small machine looking something like a clock. It can be fastened to the ceiling in any room and in case a fire breaks out there an alarm is sounded, the heat starting it. People who saw the alarm work were greatly pleased with it. The cost of putting them in is not large."

Stoner, Myers & Company are a new concern, and now occupy a three-story building in Lancaster, thoroughly equipped with machinery for the manufacture of their systems. They have already equipped a number of buildings with their alarms and are being pushed with orders for more. The capital of their company is $100,000 and a successful business doubtless awaits them.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

To advertise skillfully is part of the art of selling successfully.

THE CASE AUTOMATIC HIGH SPEED ENGINE.

There seems to be at the present time a decided and growing tendency toward the use of the self-contained, compact, single valve automatic cut-off type of engine. Its simple construction has made high speed possible, and the adoption of the best representatives of the class has been wide spread and general.

The accompanying illustrations, Figs. 1, and 2, represent the Case engine, the latest addition to the ranks, and a remarkable engine in many respects. It consists of a cylinder, having a length practically equal to its diameter, fitted into a cylindrical chamber, with its axis parallel to that of the main shaft. In this cylinder, at right angles to the axis, is bored the working cylinder of the engine, into which is fitted the piston, whose rod, working through a sleeve, is attached to the crank pin, as shown in Fig. 1. Advantage is taken of the vibrating motion of the horizontal cylinder for opening and closing the ports. The top of the working cylinder is left open through the containing case, the clearance being closed by the stationary wall of the chamber, so that when steam is admitted to the upper part of the cylinder, the pressure is downward upon the piston, and upward upon the stationary wall of the casing, and there is no tendency to press the vibrating cylinder downward. When the steam is admitted to the underside, however, there is a reaction downward upon the lower side of the horizontal cylinder, so that it is pushed against the lower wall of the chamber, with a force equal to the pull of the crank. This is counteracted by hollowing out a chamber in the lower side of the cylinder, as shown in Fig. 1, the area of which is equal to the cross sectional area of the working cylinder, minus that of the rod, and connecting this with the port, so that the pressure in this chamber is the same as that in the working chamber, thereby restoring the balance and preventing wear.

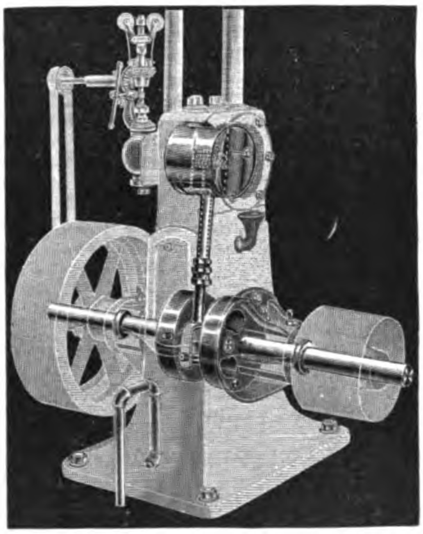

FIG. 1.—THE CASE AUTOMATIC ENGINE.

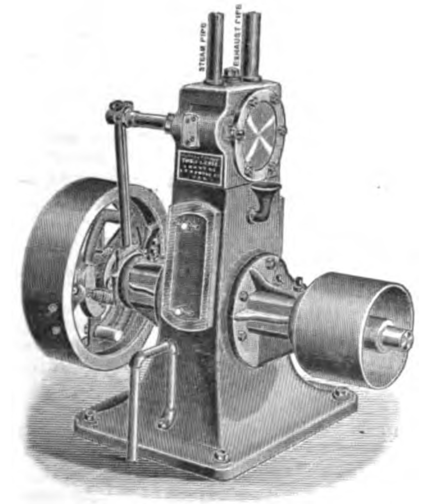

FIG. 2.—THE CASE AUTOMATIC ENGINE.

The frame of the engine is in the form of a closed trunk or casing, the bottom of which is filled with water, carrying on its surface a layer of oil. The crank dips into this at each revolution, and lubricates the moving parts. Concentric with the crank circle is placed a partition, separating the top layer of oil from the water and oil below, so that the whole mass is not churned up, and any sediment there may be is given an opportunity to settle.

A simple form of reversing motion is provided, when required. The engine is built in sizes of from 2 to 40 h. p., and in forms which allow it to be run vertically, as in Fig, 2, or bolted to an overhead floor beam, or, in fact, in almost any position. One of the smaller sizes was recently run at a speed of 2,000 revolutions per minute, and an 8 h. p. engine is now driving a dynamo in this city, which furnishes current for 100 incandescent lamps.

The general selling agency of this engine has been undertaken by Messrs. E. T. Copeland & Co., at 106 Liberty Street, New York City, who have also been appointed agents of the Ball Engine Co., of Erie, Pa., and will take charge of the New York business of that company, on May 6.

THE WERLINE MANUFACTURING COMPANY, LIMITED.

The above named concern, manufacturers of electrical and mechanical specialties, at Clark avenue, York, Pa., are getting into business shape very rapidly. They are now getting up a machine shop and foundry, with all the latest improved appliances necessary for the manufacture of their patented electrical apparatus. Among their novelties is an incandescent lamp socket, by means of which the light can be governed as with an ordinary gas burner key. They also have something in the switch line, which they consider hard to beat, making and breaking the circuit instantaneously. This form is made single pole, double pole, and three point, ranging in capacity from 5 amperes up. These will be mounted on porcelain bases and will be handsomely finished in bronze, oxidized silver, china, etc., to suit any style of house decoration. Their patent cut-out they also characterize as "somewhat of a 'hustler,'" and they already have orders for 5,000 or more from people to whom they have shown their model. It is neat, convenient and cheap. They are also perfecting a motor, which is expected to be ready by June 1st, next. There is likewise great activity in their gas lighting, annunciator and bell departments, and a fine line of each will be turned out. In short, they propose to make anything in the electrical specialty line that the trade demands. H. E. Werline is president; W. F. Wollin is vice-president; and George A. Barwitz, secretary and treasurer.

BERKSHIRE ELECTRIC COMPANY.

The Berkshire Electric Co., Pittsfield, Mass., have taken the contract to build the electric street railway in that city, from the Boston and Albany R. R. station to Pontoosuc Lake, a distance of between 3 and 4 miles. The cars will be equipped with the new slow speed Westinghouse motors and the Bemis trucks. Galvanized steel cable will be laid for ground wire, and feed wires of Shield brand wire will be run about two-thirds of the distance. Milliken iron poles will be used, and Mr. C. G. Tompkins, manager of the Berkshire Electric Co., expects to have the road in operation by June 1st. The Pittsfield Electric Co. will probably supply the power.

Mr. C. E. Merrill, the treasurer of the Railroad Co., is giving the matter the closest attention, and intends the road, when built, shall be one of the finest in the country.

The Berkshire Electric Co. have just finished the famous electric lighting plant for the residence of Geo. Westinghouse, Jr., Lenox, Mass., on which they have been engaged for the past 3 years. This plant is pronounced one of the largest and finest private plants in the country, consisting of over 1,300 lights.

The Berkshire Electric Co. are now engaged on several important plants in Massachusetts and New York. Their work takes a high rank for thoroughness and reliability.

ILLINOIS ELECTRIC MATERIAL CO.

The above Chicago concern will locate their headquarters on April 1, at 158 Fifth avenue, that city. They will open a store on the ground floor of the building and will do a retail business in the electric light and electric railway line. They will continue their large and growing wholesale business under more favorable conditions than ever, and will carry a large stock of Bishop india rubber wires, "Canvas Jacket" patent woven moisture-proof wire, and other leading and minor supplies.

THE WHELESS UNDERGROUND ELECTRIC CO.—THE CONDUIT AND HARMLESS OVERHEAD CONDUCTOR.

THE Wheless Underground Electric Company, Incorporated, of Tacoma, State of Washington, has recently come into possession of all of Mr. Malone Wheless' interests in his electric street railway inventions. These inventions cover both the conduit and overhead systems, of which a description was given some months ago in THE ELECTRICAL ENGINEER; when attention was called to the fact, that the Wheless system gave promise of solving the demand for underground electric street railways, as well as of furnishing a harmless overhead conductor for overhead lines.

The Wheless Underground Electric Company is now actively at work preparing to put in lines of street railway in several important cities; and has already commenced the construction of its first overhead line at Aberdeen, Wash. This road, when completed, will, it is claimed, be the first electric street railway ever built, of which the overhead conductor is perfectly harmless, and from which no injury can result to property or limb from the falling of the wires.

We note with particular interest the installation of this first road, and know further that it will be regarded with considerable interest by the general railway public. It is unnecessary to call to mind the accidents occurring from the falling of the electric railway wires; as well as another class of accidents due to the accidental "crossing" (by contact) of telegraph and telephone wires with overhead electric railway conductors. The Wheless system is designed to put at rest this constant cause of worry and trouble.

An experimental conduit road, built at Washington, D. C., last year under this system, has proven to be a complete success. This conduit system was tested thoroughly during the past winter, in heavy snow storms and ice, and in no instance was the working of the car interfered with.

The Wheless Underground Electric Company, as organized, has a paid up capital of $500,000, and has entered upon the construction of underground and overhead electric railways. It is the only company that is now prepared to put in an underground electric railway system which has been thoroughly tested and found to be successful.

In its overhead work, it has at once thrown itself into competition with the Edison, Thomson-Houston, and other companies putting in the overhead line.

The company is under a splendid and active management, and has already closed contracts for the construction of seven roads.

It has now three offices, one at Tacoma, Wash., a second, at Omaha, Neb., and another at Washington, D. C. The main office of the company is at Tacoma, Wash., under the management of General Manager and Vice-president, Mr. A. A. Honey, a gentleman fully posted in the details of electric street railway construction, and well known as being connected with some of the most successful enterprises on the Pacific coast.

The Omaha office is in charge of Mr. L. M. Rheem, a gentleman thoroughly posted in electric railway building. The Eastern office of the company, at Washington, is under the direction of Mr. Malone Wheless, the president of the company. Engineer H. S. Huson, of Tacoma, has resigned his position as principal assistant engineer of the Northern Pacific Railway, to take charge of the engineering department of the company, with headquarters at Tacoma, and has entered upon his duties. Under the supervision of his department all conduit and construction work will be carried forward. A branch office of the company will also be opened at New York at an early date.

In the Wheless system, the current is carried in a buried cable by the side of the track, and is fed from that automatically to the overhead or conduit trolley wire (according to whether the road is conduit or overhead). The trolley wire in either the overhead or conduit road is not a continuous conductor, but is cut in sections, insulated one from the other, and is at all times free from current except the section over which the car is passing, the current being in the power cable underground. This cable runs the entire distance of the road, and is a lead covered cable, which admits of its being laid under the surface of the street. There is no element of danger in the system, and a break in any section does not interfere with the operation of the rest of the road. If one of the sections of the overhead line should break and fall, the very fact of the parting of the wire cuts the circuit at the relay switch, and the line can be picked up with impunity and placed out of the way. The car can then be run to the next section (only a few hundred feet), where it can immediately get current and proceed on its way.

The above features apply equally to the conduit system. The trolley wire in the conduit is "dead" at all times, except the section which is in use under the car.

A striking feature of this system is the simple way in which a current of 500 volts is automatically switched from the main feed cable to any given section upon which the car is passing. This is effected by the use of a few storage cells carried on the car. These cells, when once put, in require no further attention, and simply operate a small relay attached to the pole in the overhead system, or fastened to a yoke in the underground or conduit system. This relay is placed at the juncture of the sections. The armature of the relay, when closed by the circuit of the storage cells (as the car runs on the section), simply bridges a feeder from the power cable to a short feeder from the trolley wire and lets the current pass into the trolley wire. As soon as the current passes from the trolley wire to the motor on the car, it cuts out the storage cell circuit; the armature of the relay being then held in contact by the main current which has been let in, and is flowing around one of the "poles" of the relay magnet.

The contact points of the relay are faced with carbon. This prevents any possibility of their sticking and thereby leaving the current in a section after the car has passed, it being impossible to fuse two carbon points together.

Electrically considered, this method is very simple, and Mr. Wheless has certainly shown a thorough comprehension of the character of electric railway currents, in the development of the "carbon switch." This switch is certainly a most beautiful and practical invention in its simplicity.

The reason why the *continuous* conductor cannot be used in the conduit, is the fact, that the "escape" in the line would be too great. The method under the Wheless system of carrying the current in a cable (where no escape can take place), and keeping the trolley wire in the conduit free from current at all times except in the given section, certainly avoids all "escape," and there should be no reason why this method of electric railway propulsion should not be successfully operated for underground electric railways.

It is needless for THE ELECTRICAL ENGINEER to call to the attention of the railway public the great demand for a competent and efficient underground electric railway system, and the new company certainly enters the field with our best wishes and congratulations.

The officers of the company are:—President, Malone Wheless, of Washington, D. C.; first vice president and general manager, A. A. Honey, Tacoma; second vice president, Charles M. Johnson, Tacoma; secretary, Andrew L. Horner, Tacoma; treasurer, C. S. Bridges, Tacoma; chief engineer, Herbert S. Huson, Tacoma. Three additional trustees, besides the officers named are: E. N. Ouimette and John B. Cromwell, Tacoma, and L. M. Rheem, of Omaha, Neb.

The counsel for the company are Judge Galusha Parsons, of Tacoma, and Mr. William H. Singleton, of Washington, D. C.

NEW CROCKER-WHEELER CATALOGUE.

Those who have not as yet perused the new catalogue of the Crocker-Wheeler Electric Motor Company, New York, will find within its covers, much of interest concerning electric motors generally and the Crocker-Wheeler perfected electric motors in particular. A handsome illustration of one of these motors printed in several colors makes an attractive frontispiece to the catalogue, which throughout shows evidence of much care and attention having been spent in its preparation and publication.

The text includes an interesting description of the construction of the Crocker-Wheeler motors, directions and suggestions for setting up and running them, and other valuable data regarding dimensions, horse power, cost, etc.

The construction and operation of a new indestructible resistance box made entirely of slate and iron, for starting, stopping and regulating their motors, is described in detail. The latter half of the catalogue is devoted to the smaller power motors, 1-6, 1-8 and 1-12 h. p., made by the company, and their numerous and useful applications. The text is well illustrated.

SOUND ALUMINUM CASTINGS POSSIBLE BY USING PLUMBAGO FACINGS.

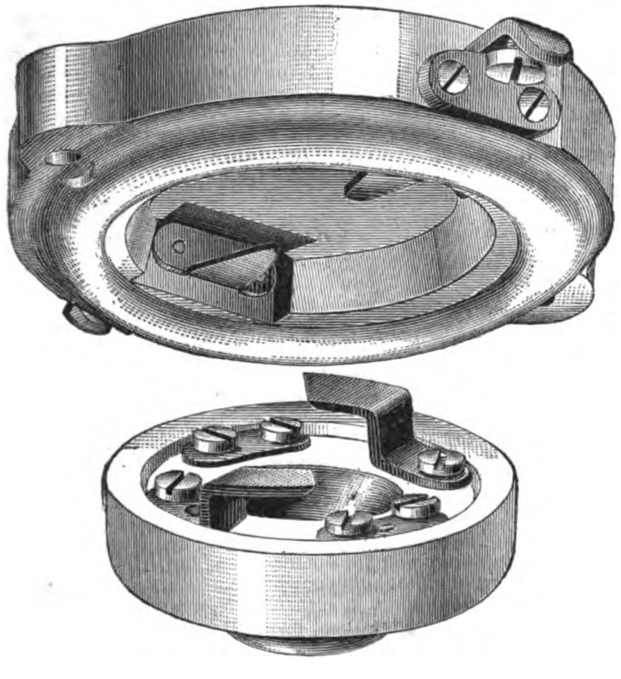
"Sound castings of aluminum can be obtained in dry sand moulds preferably lined with plumbago. The metal should be heated to a temperature very little above its melting point, and should be poured quickly. The shrinkage of the above metal is 17-64 inch to the foot (2.26 per cent. of the length of the mould)." The above statement is not only true as to aluminum, but of all metal castings. Actual sales of plumbago show that barrels of plumbago are now used in shops where pounds were formerly called for. Its use is becoming universal. The use of a plumbago facing absolutely guarantees to the casting a smooth surface and bright color. Caution is suggested when purchasing to obtain exactly the kind wanted for the different work. It can be said of plumbago as the Irishman said of whiskey, "None is bad, but some is better than others." One kind of plumbago is better applied by the shake-bag, and if the brush is used, another kind will prove better. One preparation of plumbago will "sleek," another will not. Another kind is more useful for light castings, another kind for heavier work.

Good plumbago will stand the heat and will neither burn or run before the molten metal. A wash of plumbago for cores, loam

work, and dry sand castings is indispensable. The Dixon Crucible Co., of Jersey City, N. J., have made a patient study of the subject, and being the only miners of plumbago who afterward prepare it for its many uses, they can give advice on the subject, not elsewhere obtainable. On application, they will send a little book free and post paid, that contains more information on the subject of plumbago than is elsewhere in print in any language.

THE CARTWRIGHT WATERPROOF CUT-OUT.

The accompanying illustration represents one of several new patterns of rosette, which include some novel and useful features. In the plain pattern Cartwright porcelain rosette and the ornamental pattern of the same, as will be seen, the brass connectors to which the wires are fastened have a slight projection from the base underneath the overhanging screw-head, opposite the point where the wire rests when it is clamped. The object of this projection is to prevent undue torsion of the screw when it is turned firmly down to clamp the wire. When there is no such support there is a tendency to throw the screw-head out of plumb and damage the connection, whereas, when the screw-head is equally supported on both sides, on one by the wire itself, and on the other by the projection, better results are obtained.



Cartwright Waterproof Cut-out.

In the Cartwright waterproof cut-out this feature in the connector is not only present, but special stress is laid upon the fact, that there are no screw-holes or metallic connections of any kind leading from the inside of the cut-out that might form contact with a damp ceiling.

These cut-outs are being placed upon the market by E. S. Greeley & Co., of this city.

A WESTINGHOUSE PLANT IN AUSTRALIA.

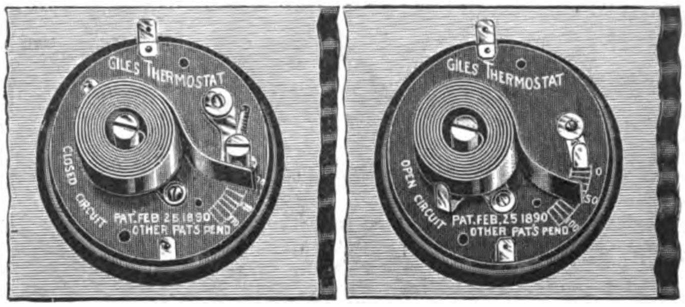
According to recent reports from Australia, the people of that country are now rapidly awakening to the advantages to be derived from the utilization of electric light and power.

A central station plant of electric lighting has just been completed at New Castle, which operates the Westinghouse system of alternating current central station apparatus.

The plant comprises arc and incandescent lamps. The dynamos are driven by Westinghouse compound engines. The plant is composed of Westinghouse alternating current dynamos and exciters. Steam for the electric plant is generated by Babcock and Wilcox boilers, working at 120 lbs. pressure per square inch, The switchboard is a very complete one, and by its means the light can be switched on and off at any given point in the town. The street lights are worked on two independent circuits and there are also two independent circuits for private lighting. The exciters and dynamo for the plant were manufactured by the Westinghouse Electric and Manufacturing Company, at Pittsburgh, Pa. The installation of the apparatus was superintended by an engineer of that company, who had been sent purposely to Australia. The plant gives great satisfaction to the public and city council, and is attracting the attention of other municipalities.

THE GILES AUTOMATIC THERMOSTATS.

The Giles thermostats are founded upon the well-known principle of difference in the expansion and contraction of metals. They are made from special grades of metals that, after severe tests, are found to produce the best results. They are free from the objections of liquid thermostats, in this, that they will not make contact when the floor or portion of the building where the thermostats are placed, is jarred. They are nicely finished, and all contact points are made of platinum. Fig. 1 represents a closed circuit thermostat, which is adjusted by means of a screw on the right. It is made to adjust from 70 degrees to 170 degrees, and has one-half inch movement in 100 degrees. Fig. 2 represents an open circuit thermostat, which is adjusted by means of a lever below the coil and has an adjustment of 100 degrees above the temperature of the room when placed in position and has one-half inch movement in 100 degrees. Fig. 3 is a side view of the thermostats. These thermostats are being placed on the market by the Central Electric Company, of Chicago.



Figs. 1 and 2.—Giles' Thermostat.

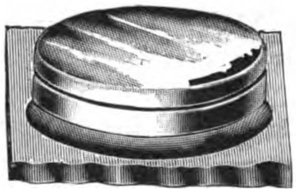


Fig. 3.—Giles' Thermostat.

TELEPHONE KERITE CABLES.

The American Telephone & Telegraph Co., better known as the "Long Distance" Telephone Co., has just given a contract to A. G. Day, of 16 and 18 Dey street, the manufacturer of "Kerite," to make and lay a cable across the Hudson river. This cable is to be of the anti-induction type and made to special specifications. It will be 5,350 feet in length, and contain 18 conductors. The cable is to be in position by June 1st, and makes another addition to the large number of Kerite cables already in operation at this point, some of which have been in uninterrupted use for nearly twenty years. The new cable will be laid under the personal supervision of Mr. Geo. B. Prescott, Jr., general agent for the concern.

STANLEY ELECTRIC CO.

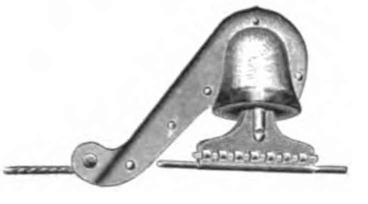
The Stanley Electric Co., of Pittsfield, Mass., has leased the second story of the Morton Building in order to have more room for its business, and the machinery is being put in position as quickly as possible.

THE PATENT CENTENNIAL CELEBRATION.

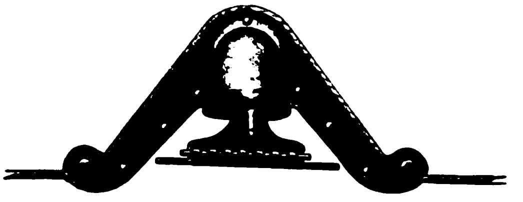
Arrangements are rapidly maturing for the patent centennial celebration at Washington, on April 8, 9 and 10. The programme has already been outlined in these pages. Among the papers of special interest to electrical engineers may be noted that of Prof. Thomas Gray, on April 9, on "The Inventors of the Telegraph and Telephone," and of Prof. C. F. Brackett, on "The Effect of Invention upon the Progress of Electrical Science." The paper of Judge Taylor, of Indiana, on "The Epoch-Making Inventions of America," on April 8, will also contain references to electrical advancement and discoveries.

ANDERSON INSULATORS.

THE "trolley wire hanger" and the "curve pull-off" described herewith, are specimens of a very strong and substantial order of overhead line devices. A composition known as the "Etna" insulating material is moulded into the bells. It is said to be practically indestructible, and to afford very high insulation. The wire-holding device is in the line of the latest development in that sphere. It it entirely simple, and would appear to be very effective. The cut shows clearly the action of the clamp when the pin is driven into place. These Anderson insulators are handled by The Electrical Supply Co., of Chicago.



THE ANDERSON CURVE PULL OFF INSULATOR.



THE ANDERSON TROLLEY WIRE HANGER.

A RUBBER INSULATED SCREWDRIVER.

THOSE who are accustomed to working around live conductors will know how easy it is to get an unpleasant shock by touching a finger to the shank of the screwdriver, and how readily the tip of the tool is burnt by shunting considerable current through the shank. All this would be avoided by having the shank insulated nearly to its tip, as is done in the case of the new screwdriver shown in our cut. The metal shank is flattened and bent into a loop at one end, and then moulded into a rubber protecting handle. Vulcanized rubber gives a high and lasting insulation and also has the toughness and durability needed in a tool-handle, hence it unsurpassed for making a reliable safeguard of this type.

A RUBBER INSULATED SCREW DRIVER.

The rubber insulated screwdriver is made in a number of sizes, suited for use in various places. George Cutter, of Chicago, has the Western agency for it, and has already sold quite a number.

"SUPERIOR MERITS," "PERFECT SATISFACTION."

The following is a recent communication received by Kidder's Electrical Depot:—

DOVER, N. H., March 17, 1891.

JEROME KIDDER MANUFACTURING Co., 820 Broadway, New York City.

Gentlemen:—

* * * I have sold several of your Faradic Batteries, which I am pleased to say are giving *perfect satisfaction*. I have a customer who wants a No. 5 Apparatus with tip battery on account of the *superior merits of the No. 5 coil* which I have explained to him.

Yours truly,

CHAS. H. DAME,
No. 11 Essex street.

Dealer in Electrical Supplies.

CINCINNATI TRADE NOTES.

THE CARD ELECTRIC MOTOR AND DYNAMO Co., of Cincinnati, are getting out a new catalogue, which is expected to compare favorably with anything of the kind ever issued. It will be tastefully arranged and profusely illustrated.

NEW YORK NOTES.

REED & MCKIBBIN, the consulting electrical engineers and contractors, of 32 Liberty street, will remove on May 1 to 2 Wall street. They succeed to the business of Thompson, Reed & Co.

WESTERN TRADE NOTES.

THE ELECTRICAL SUPPLY CO., of Chicago, is pointing with considerable pride to a large order for Shield Brand wire just taken in a Western city. This pleasant state of mind is due, not so much to the size of the order, though it was a handsome one, as to the fact that it was taken in the face of unusually urgent competition. The E. S. Co. attribute this success to the well-known merit of the wire, and not to exceptional selling abilities. "It is the moisture-proof quality that counts."

THE GLOBE CARBON CO., of Cleveland, O., are going to build new works, right away, of treble their present capacity. Their business is increasing so rapidly that in their present quarters they find it difficult to keep pace with their orders. Their new factory will be pushed right through and they will then be in a position to meet the largest demands in the most prompt manner.

THE BALL ENGINE CO., manufacturers of high speed automatic cut-off engines, Erie, Pa., are very busy filling orders for their well-known engines. They are largely extending their capacity. Such a general favorite for electrical and other power purposes has this engine become that this step has been found an imperative necessity. Their new building is now well under way, and when completed will make the factory one of the most extensive and best equipped of its kind. They are just shipping a 250 h. p. cross compound condensing for the Buffalo electric street railway plant, and a 300 h. p. triple expansion engine to Rochester for street railway work.

NEW ENGLAND TRADE NOTES.

THE PETTINGELL, ANDREWS COMPANY report business as beginning to be brisk for the spring, after some weeks of unusual slackness. They have recently received some large orders for supplies, and are paying special attention to electric railway specialties. Among their most recent contracts is one for the complete equipment of feeder wire for the Springfield Electric Railway Company, Springfield, Mass., which calls for several miles of heavy insulated wire. They have also the order for line wire equipment of the Holyoke Street Railway Company, and they have just received a very comprehensive order for feeder wires, and all electric fittings and supplies, for the Newburyport and Amesbury Street Railway Company, of Newburyport, Mass. The Newton and Watertown Gas Light Company, of Newton, have also sent them some large orders for wire recently, and altogether the prospect for a good business is extremely bright.

THE EVANS FRICTION CONE COMPANY, of Boston, report the sale of their frictional system of driving to the following plants: Wm. Ruehl Brewing Company, 200-light dynamo; Edison Electric Illuminating Company, New York, friction for motors for ventilating machinery; Westinghouse Electric Manufacturing Company, Pittsburgh, for an electric plant on a government steamer, the engine and dynamo being on the same bed-plate; Derby Gas Company, Birmingham, Conn., for 50 arc light dynamo; Hughes & Gawthrop Company, Pittsburgh, for 50 arc light dynamo; Thomson Electric Welding Company, Lynn, Mass., for 100-light dynamo; Bridgeport Electric Light Company, Bridgeport, Conn., for four 50 arc light dynamos; Brooks Bank Note and Lithograph Company, Boston, for 100-light dynamo; Ames Building, Boston, for two 275-light dynamos.

MR. W. H. ELKINS has just perfected an arc light dynamo with an absolute system of regulation. All arc light dynamos in the market to-day require a regulator to protect the dynamo, when lamps are suddenly cut out of circuit. Mr. Elkins has been at work on the subject of regulation for years, and has already patented several regulators, but has now discovered a method of winding a dynamo by which he gets a perfect regulation. He can cut out any number of lamps at once without interfering with the running of the machine, or heating the armature or fields, and can short circuit the machine 60 times a minute (for the purpose of testing it) without any injurious effect. It looks as if Mr. Elkins had a valuable patent.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XI. APRIL 8, 1891. No. 153.

EXPERIMENTS ON THE TRANSMISSION OF POWER AT VERY HIGH POTENTIALS.

PROBABLY the most notable feature of the Electrical Exhibition at Munich in 1882, was the demonstration by Deprez, of the practicability of transmitting power electrically over long distances. For this purpose, it will be remembered, Marcel Deprez employed two machines, one acting as a generator at Miesbach, and a second as a motor in the exhibition building at Munich, 37 miles distant, the current being sent over an iron telegraph wire 4½ mm. in diameter. The difference of potential at the generator was 1,343 volts and that at the motor 850 volts, while the actual work at the motor measured only ¼ h. p.

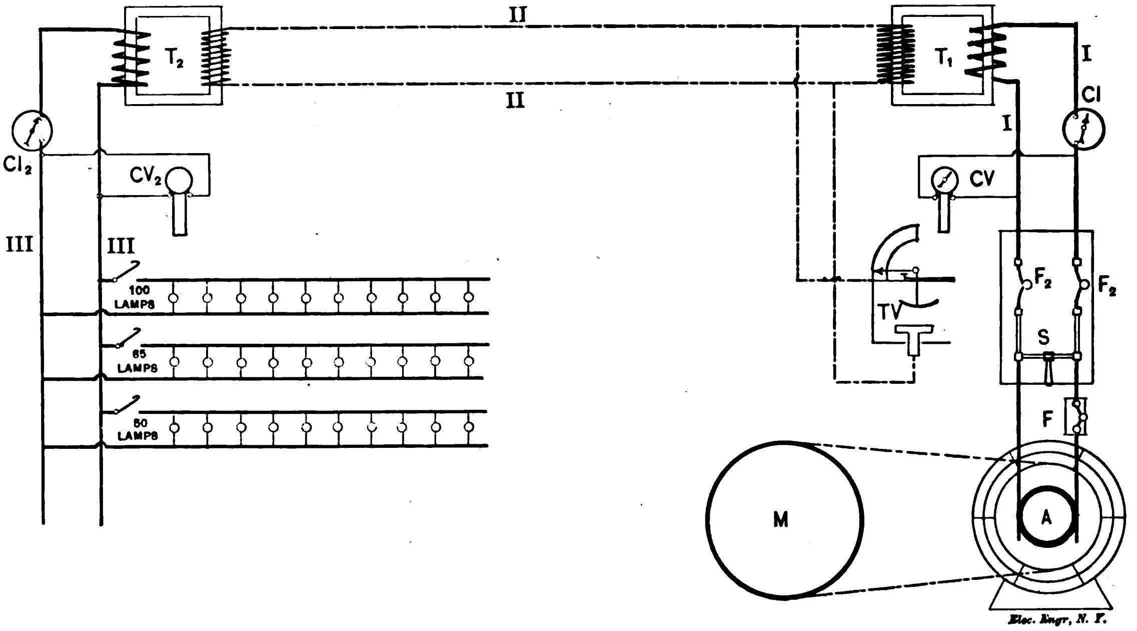


Fig. 1.—Electric Power Transmission at 30,000 Volts Potential.

As a demonstration of the improvements introduced since that time no better example could be afforded than the high tension transmission which it is proposed to show in connection with the Frankfort, Germany, electrical exhibition to be held during the present year.

The plan contemplates the transmission of 300 h. p. of the water power of the River Neckar, at Lauffen, to Frankfort, a distance of nearly 115 miles, by means of a copper wire 4 mm. in diameter. To accomplish this without very heavy loss in the conductors will evidently necessitate the employment of very high potentials, and in order to obtain data for the proposed work, a test installation was recently made at the works of the Oerlikon Company, near Zurich, who, in connection with the Allgemeine Elektricitätsgesellschaft, of Berlin, will undertake the transmission referred to.

Unlike the Deprez experiments, the present will be carried out by the aid of the alternate current transformer. The arrangement of the apparatus in the preliminary test is shown in the accompanying diagram, Fig. 1, in which I represents the generating station, II the line, and III the receiving station. As will be seen, an alternator A was directly driven from the motor by belting, and by changing the speed, the potential could be varied from 40 up to 100 volts. The alternator generated a heavy current at a low voltage. For the proposed installation at Lauffen, the voltage will be 50 volts and the current 4,000 amperes. In this respect the system differs materially from the ordinary alternating current transformer systems. According to the opinion of the Oerlikon firm, the employment of wires of large size, with consequent decrease in the number of coils, will allow of a cheap construction of the dynamo, and afford much greater safety of operation. Quite apart from other advantages, the low voltage of the alternator removes the factor of danger for the attendants during the operation. From the alternator, the low potential current is carried to the transformer T_1. On the way it passes through a single pole fuse F, through a double-pole single-throw switch S, and double-pole fuse F_2. In case of a fault in the insulation arising from too heavy load, or of a short circuit, the current would increase so much that the fuse, of the Cockburn type, will be blown; the weight of the leaden ball, suspended from the leaden fuse wire, tears apart both ends of the same, so that the circuit cannot be closed again by the two ends of the fuse melting together. The current is measured in the primary circuit by the current indicator C I, and its potential by the Cardew voltmeter C V.

The transformer T_1, designed by Mr. C. E. L. Brown, of the Oerlikon Works, is shown in two views in Figs. 2 and 3. It consists of a rectangular laminated iron core, on which both the primary and the secondary windings are placed, insulated from each other. The magnetic circuit is closed by two U-shaped iron pieces.

Experiments have proven that for such high potentials, hard rubber a few milimetres thick is only a safe insulator as long as it is absolutely homogeneous ; as soon, however, as it gets a crack, the air which enters allows discharges of electricity to take place. Some kinds of oil have proven to be as good insulators as hard rubber. In order to prevent a discharge in the transformer, the latter is placed in a vessel filled with oil, the latter thus filling out all interstices and expelling the air which endangers the insulation. According to Mr. Brown's information, these transformers have proved to be quite safe, even at a potential of 50,000 volts. The transformer has a ratio of one to three hundred. The primary potential of the alternator of 40, 50, 65, 100 and 110 volts used for the experiments, thus produced a potential of 10,000, 15,000, 20,000, 30,000, 33,000 volts, respectively, in the secondary circuits. In the experiments, the line consisted of 7 kilometres of bare copper wire, 4 mm. in diameter, mounted in four parallel rows on the same supports by means of Johnson & Phillips oil insulators. The type of insulator proposed for the actual line from Lauffen to Frankfort is shown in Fig. 4.

The insulation of the line was tested by means of artificial rain, produced by the spraying of water from a hose. A Cardew voltmeter connected with the high potential secondary conductor indicating up to 100 volts, was connected to earth, and did not show any deviation. During a snow storm which took place, the same line did not show any leakage. The number of insulators used for this test amounted to 120. The Oerlikon works made use of spans of 80 to 100 metres, with copper wire of 4 mm. diameter. The oil insulators employed thus represented the insulating resistance of a line 10 to 12 kilometres long.

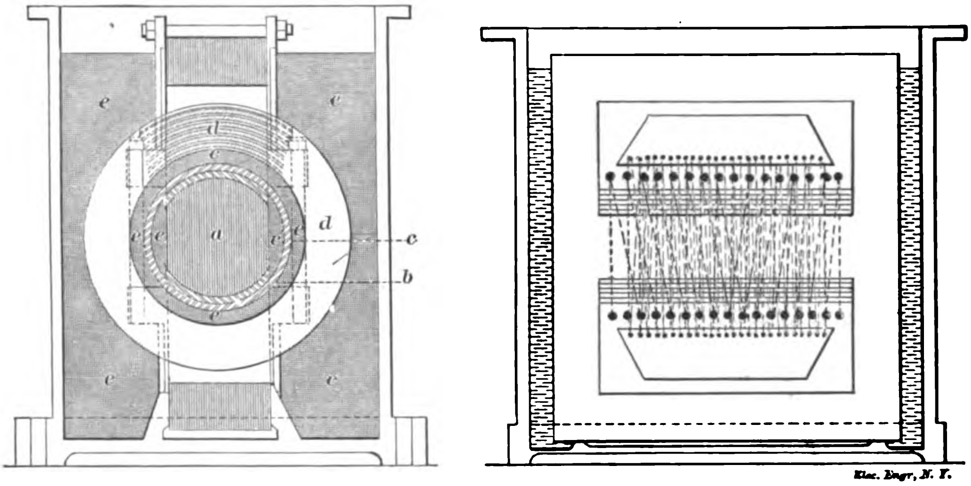
In the secondary circuit. the potential was measured by means of a Sir William Thomson voltmeter TV, which can be used for measuring potentials as high as 50,000 volts. A comparison made between the indications of this instrument and those of the Cardew voltmeters CV gave very satisfactory results. The secondary circuit is connected with a transformer T_2. Its ratio of conversion is also from 1 to 300, so that it reduces the voltage on that of the primary conductors equal to that of the alternator. This transformer is also placed in a vessel filled with oil. The tertiary circuit at the receiving station had connected with it the current indicator CI, a Cardew voltmeter CV, and three series of 10 incandescent lamps run in multiple for 50, 65 and 100 volts, which could be switched on or off by the switches SS.

Special interest was excited by the experiments in the working of the fuses, and the induction in a telephone wire running parallel close to the power transmission line. The fuses were tested by making a direct short circuit, as well as by making use of the discharge current. They were inserted in the primary circuit because the small current used in the secondary circuit would necessitate the use of too fine wire. As soon as the secondary circuit was short circuited by means of a copper wire, the fuse was instantly blown. The short circuit was made by dropping a bare copper wire on the two secondary conductors. As is known, the blowing out of the fuses is accompanied by a small explosion ; it was impossible to notice the smallest difference of time between the noise of the short circuit in the secondary wire and the explosion of the fuse. The extraordinary quick working of the fuse was proved by the fact that neither the secondary wires nor the copper wire used to produce a short circuit showed any traces of burning, notwithstanding the fact that the numerous short circuits which were made caused the copper wire and the conductors always to touch each other at the same place.

In order to produce a discharge, two pieces of wire were connected with the secondary conductors, placed 22 millmetres apart. As soon as the secondary potential attained about 18,000 volts, the first discharges, accompanied by a dim light took place. At a higher voltage an arc was produced, causing at the same time interruption of the current by the blowing of the fuse.

In order to investigate the effect of the secondary current on telephone circuits, a telephone loop was run on the same poles carrying the secondary wires. It must be remarked that the secondary wires were arranged in four parallel rows, in order to enable the large amount of wire to be stretched within the limited space available for it. The speaking through the telephone did not meet with any difficulties, although their was a small noise caused by induction.

The experiments, which have been of a qualitative character, proved that the transmission of power installation between Lauffen and Frankfort will not only be possible, but also absolutely safe. The working of the fuses evidently proved that short circuits which might happen by the falling or bending over of poles, will cause an instantaneous interruption of the whole plant. In the some way the installation, tested under very unfavorable circumstances, proved to be highly satisfactory.



FIGS. 2 AND 3.—TRANSFORMER FOR 30,000 VOLTS POTENTIAL.

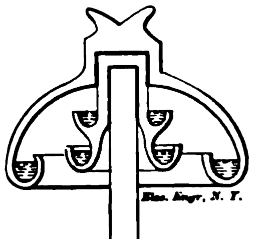


FIG. 4.—OIL INSULATOR.

LIVINGSTON, MONT.—The Livingston Electric Light Company have executed a mortgage to the Minneapolis Trust Company for $30,000 upon their plant. This money is secured to take up floating indebtedness and for the purpose of increasing the plant and extending the service.

THE STANLEY TRANSFORMER.

Mr. Wm. Stanley, Jr., whose brilliant successes in the alternating current field are well known, has recently organized the Stanley Electric Manufacturing Co., of Pittsfield, Mass., where work is now actively going on in the development and manufacture of a series of electric lighting specialties.

Among the first fruits of Mr. Stanley's labors is an improved transformer, in which he has embodied methods of construction which have increased not only the electrical, but also the mechanical efficiency of this important piece of apparatus.

Considering first, the electrical efficiency of the new Stanley transformer, which is shown in the accompanying engravings, the 20-light converter at full load has been found to have an efficiency of 94.3 per cent., and its peculiar design makes it possible to obtain a very high efficiency even on so small transformers as five-lighters. The percentage of variation of E. M. F. in the secondary, between full and light load, is only 1.3 per cent.

Other things being equal, one of the best tests of the commercial value of any apparatus is the amount of useful work done per unit of weight, and in this respect the Stanley transformer shows up very favorably, the 20-light transformer, for instance, giving 12 watts of useful energy per pound of weight.

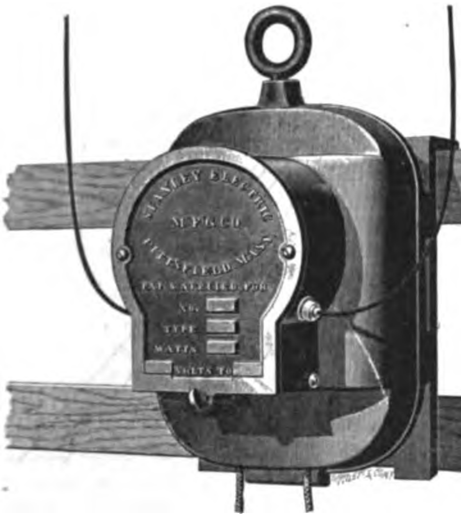

Fig. 1.—The Stanley Transformer.

The arrangement of the fuses so as to allow of easy and safe handling of the transformers has been very neatly worked out by Mr. Stanley, and is clearly shown in the engraving Fig. 2. As will be noted, the secondary fuse is done away with entirely, as every secondary is fused where it enters a building. The primary fuse wire or link is carried on a porcelain block or plug, and can be secured in place while the block is held in the hand. The station may have a number of extra plugs, and, to replace a fuse which burns out, it is only necessary to open the door by turning a thumb-screw, remove the plug, insert another and shut the door; or a new fuse may be attached and the same plug replaced. The same size of plug fits all different sizes of transformers up to 100 lights.

The fuse box is entirely of porcelain, every part being thus perfectly insulated and fire-proof. The two fuses are entirely separated by the porcelain partition in the fuse-box, thus preventing any chance of short circuit from one to the other, and the unusual length of the fuse itself, insures a complete rupture of the circuit and prevents any possibility of arcing.

The insulation of this transformer possesses a very great resisting power to high potential discharges, and the method of winding the coils renders the chance of a cross extremely remote.

The new Stanley transformers are made in sizes of 5, 10, 20, 30, 40 and 100 lamps capacity, and are wound for both 1,000 and 2,000 volts primary, with either 100 or 50 volts secondary. The company is also prepared to build special transformers for any desired purpose.

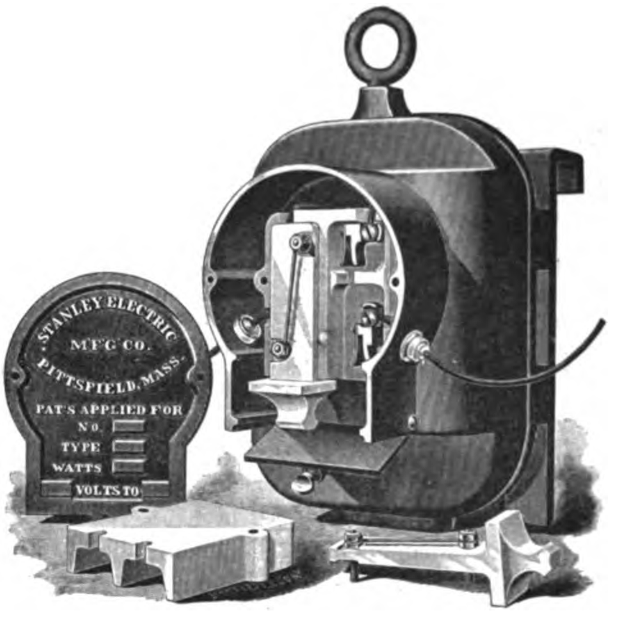

Fig. 2.—The Stanley Transformer.

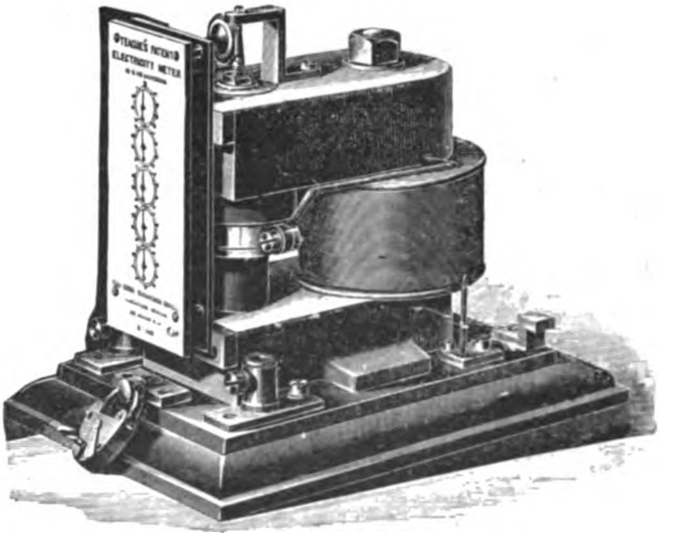
THE TEAGUE METER.

At the Electrical Exhibition now being held at the St. Pancras Vestry Hall, London, is shown the Teague watt-meter, manufactured by the Acme Electric Works, and represented in the accompanying illustration.



The Teague Meter.

This meter consists of a horse-shoe electro-magnet with a hollow revolving cylinder or drum inserted in an annular space bored near the pole. The series current enters at the bottom by the axis of the cylinder, which projects into a mercury trough, passes thence to the top, radiates by the cap of the cylinder to the exterior, and passes down to another mercury trough. In its arrangement the meter resembles that designed by Mr. Weston some years ago.

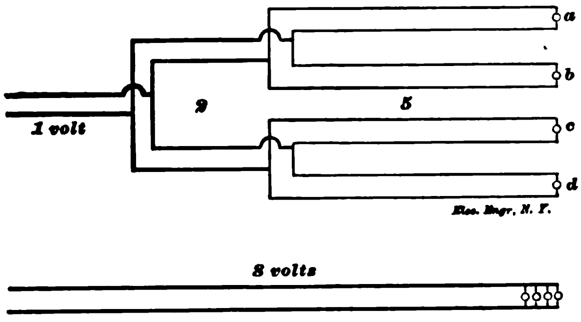
RULES AND FORMULÆ FOR INCANDESCENT LAMP WIRING.—II.

BY

Carl Hering

To calculate the wires for a building with independent lamps, lay them out so as to approach as nearly as practicable the best distribution as described above, making common mains as short as possible, and individual branch wires as great a proportion of the whole as possible; then determine on the total loss, for instance, four volts, and divide it amongst the leads so as to have as small a part as practicable (say, one volt) on the common main, and the other part (three volts) again divided, if necessary, on the distributing branch wires. Calculate the size of each wire from the number of lamps supplied by it, and from this portion of the total loss allowed for that part of the whole lead. The lamps will then be dependent on each other only in so far as they are on common wires, and to an amount that other lamps effect the loss only on this common wire.

To illustrate some of the points mentioned above by an actual (exaggerated) case, suppose the leads for four lamps, *a*, *b*, *c*, *d*, Fig. 4, be subdivided as shown, and suppose the total loss of 8 volts be divided into 5, 2 and 1, as indicated, on the separate mains and branches; the relative distances being in the proportions of the diagram. The loss is proportionately small on the common mains and large on the individual branches. Now, taking any one lamp, as *a*, its voltage will be increased as follows: With *b* turned off, 1¼ volt; with *c* or *d* turned off, ¼ volt; with *c* and *d* both turned off, ½ volt; with *b*, *c* and *d* turned off, 1¾ volt. This shows that lamp *a* is dependent on the others in proportion as it is on common mains with them, and on the loss of volts on the common mains, which is small in this case.



FIGS. 4 AND 5.

Now, for the sake of comparison, let the four lamps be supplied by a single pair of mains, as in Fig. 5, with the same loss of 8 volts. Turning off one lamp increases the voltage of the others, 2 volts; with two lamps turned off, 4 volts; and with three lamps off, 6 volts. This shows how very great the difference is, namely, a maximum of 6 volts in Fig 5, as compared to 1¾ volts in Fig. 4. The weight of wire in Fig. 4 is only slightly higher, namely, as 23 to 20. If now, the wire in Fig. 5 be made larger, so as to have the same maximum *variation* in volts as in Fig. 4, namely, 1¾ volt, the total loss would have to be 2 volts, and this would increase the weight of wire to about three times that in Fig. 4, showing the advantage in subdividing the leads, aside from the fact that Fig. 4 is a distribution, (as the lamps might just as well be at the same distance in different directions) while that in Fig. 5 is not. The actual figures will, of course, vary greatly under different circumstances, and no general statement can be made regarding the amount of gain.

In referring to the dynamo, in the above deductions, it was understood to mean the place from which distribution begins, that is, the centre of distribution, or the common point at which the potential is kept constant. In wiring large buildings or spaces, it is usual to run a pair of large mains to a central point from which distribution begins; this pair of mains, provided it is the only one from the dynamo, is not included in the above discussion, as it is supposed that the dynamo is so regulated as to keep a constant potential at the far ends of this pair of mains, that is, at the centre of distribution; if the dynamo does not do this, or if there is more than one pair of such mains, then it brings the centre of distribution back to the dynamo, thus making these mains part of the distribution.

A great mistake is often made in supposing that a dynamo can keep the potential constant at more than one distant centre of distribution, without special apparatus at the dynamo. This refers, of course, to a system of independent lamps. Suppose all lamps are turned on at one centre, and only one lamp is on at the other, this lamp will be run too high, as the dynamo must be kept at the same high potential on account of the lamps on the other centre. It can be accomplished only in one of two ways, first, approximately, by making the loss on the mains very small; secondly, by regulators in each of the original branches from the dynamo.

It has been suggested to put lower voltage lamps at the most distant centres, and higher voltage lamps at the nearer ones, on account of the greater loss in the longer mains. It is a question whether this is practicable, for a number of reasons. A lower volt lamp requires a greater current and for this reason alone, a larger wire. It is not a good practice to have lamps of differing voltages in stock for one and the same building or installation, unless there is a reliable person to take charge of their proper placing.

In the three-wire system there are practically two lamps in series, and, therefore, the current need be sent out and back only once for every two lamps; this requires but half the wire (in cross section) otherwise necessary for the same number of lamps. Furthermore, the loss of volts is divided between two lamps, and it can therefore be made twice as great as in the simple system; this halves the quantity of wire again, making the total one-quarter as great as for the two-wire system. To carry the current for any lamp which may not at the time have another in series with it, a third or neutral wire is laid, which, in wiring buildings, is usually made the same size as the other two; this increases the wire by a half, making the total three-eighths of that required for the simple system. To calculate the leads for the three-wire system, proceed as in the simple system, and divide the cross section obtained by four, using three wires of this cross section. The same result would, of course, be obtained by using one-quarter the number of lamps, or one-quarter the distance, or four times the loss.

Fusible cut-outs.—The general principle of safety or fusible cut-outs is that they protect from a dangerous excess of current those wires which are *beyond* them, as distinguished from the wires between them and the dynamo, which are not protected by the fuses. They should therefore always be placed at the *beginning* of a wire (that is, at the end toward the dynamo) and not at the lamp end. Furthermore, they should be made so small that they protect the *smallest* wire lying beyond them, up to the next fuse; this is not infrequently overlooked, and may be a source of great danger. A thick wire is sometimes protected by a large fuse, because it is a thick wire, nothwithstanding that a small wire is attached to it, unfused; there is always great damage in such cases. It follows, therefore, that whenever the wire changes its size, a fuse should be placed, unless the fuse preceding it is small enough for the smallest wire beyond it. In general, therefore, a fuse should be placed at the beginning of every branch circuit, except as explained.

If only one side of a circuit is protected by fuses, the building is not completely protected, as there are possible cases in which a wire might become overheated, as, for instance, when a heavily fused wire and a light unfused wire are both grounded or in contact. Fuses should therefore always be "double-pole."

It has been suggested to make the fuses of copper wire of a certain number of sizes smaller than the size of the wire to be protected by it. This would be a very good general rule and guide, but the temperature of the fused copper is so very much higher than that of lead alloys, that there would be danger of fire caused by scattering of this melted copper.

Fuses should be marked with the current at which they will fuse, but as such marks are sometimes very unreliable, even with fuses sold by otherwise reliable companies, a careful engineer will always test a sample fuse before using them. Some fuses are marked with the number of lamps normally supplied by them, others with amperes, others with the fusing current, etc.; unless it is known what such marks mean, it is not safe to trust them.

THE VERSTRAETE CONDUIT AND TROLLEY FOR ELECTRIC RAILWAYS.

The accompanying illustrations show a conduit and trolley system for electric railways invented by Mr. Edmond Verstraete, an electrician of the railway department of the Thomson-Houston Electric Co., and now in charge of the electrical installation of the Union Depot R. R. in St. Louis. The system is applicable to the ordinary cable conduit although a specially constructed conduit is more suitable for rapid construction. Fig. 1 is a transverse section and Fig. 2 a side elevation of the conduit and trolley, from which it will be seen that at the bottom of the conduit is placed a light T rail, on which travels the trolley truck. The trolley is supported on two double flanged wheels arranged tandem between the two main plates or frame pieces.

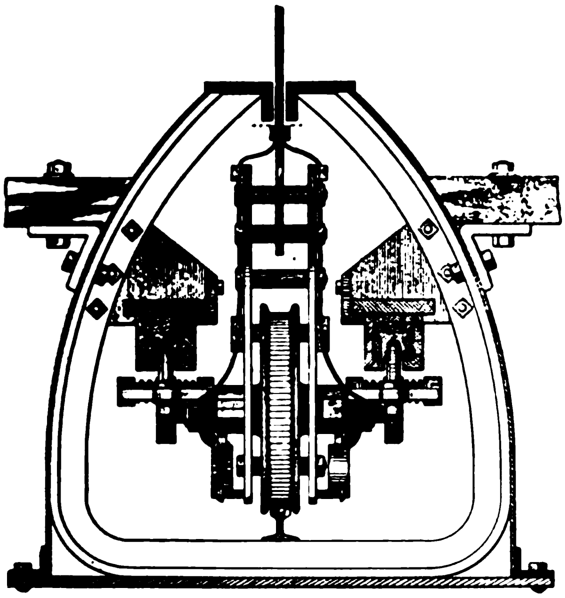


Fig 1.—The Verstraete Railway Conduit.

Four contact wheels, two on each side of the frame, make connection with the positive and negative mains. The contact wheels are carried on the ends of four levers which are pivoted on a centre common to all, and are pressed upward by means of counterweights or springs which cause the wheels to be kept in constant contact with the supply mains.

The axles of the contact wheels have a limited lateral motion in their bearings, and coiled springs are placed on the axles on each side of the wheels to give them an elastic motion laterally. The contact wheels are insulated from the hubs by means of a web of insulating material, and the rims of the wheels make contact with four spring shoes which are also insulated from the frame piece by means of insulated binding posts. Two binding posts on one side are connected together forming, say, a positive lead, while the two binding posts on the other side are also connected together, forming the negative lead, both of which are carried upward through two separate spaces or channels in the main column to the motors and controling devices on the car.

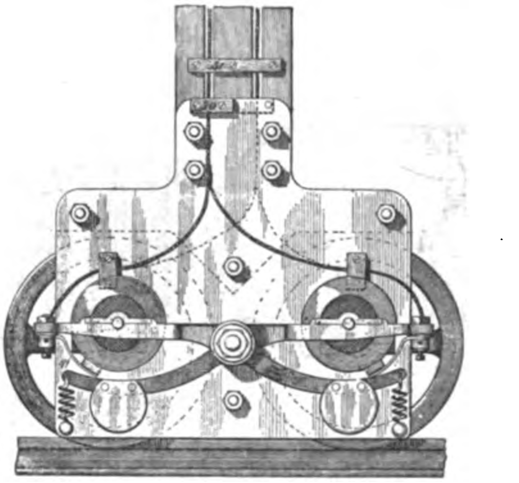

Fig. 2.—The Verstraete Railway Conduit.

The mains are formed of bars of channel iron, as shown in Fig. 1. The bars can be made of any length and are joined together by expansion joints to provide for expansion and contraction. The bars being of considerable sectional area, can, when properly bonded, be made to carry the entire current without feeders.

In construction, the mains are first laid in the wooden boxing, which has a longitudinal opening in its bottom conforming to the channel in the bar. The boxing is well clamped into position and then filled with an insulating compound, which is run in while hot, and when well set the cover is fastened on. The entire main, except its under or channelled part, is therefore entirely covered with insulating material. The boxing is supported by cast iron brackets attached to the yoke pieces at regular intervals.

THE HUNTER AUTOMATIC SHUNT.

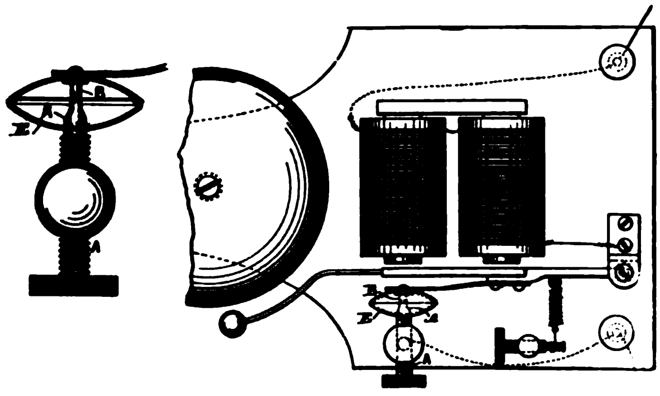
In the employment of incandescent lamps in series lighting, it is necessary to maintain constant current on the line, even though one or more lamps give out. To effect this, Mr. Rudolph M. Hunter, of Philadelphia, has invented an arrangement in which the current in the line is greater than that required in any one lamp in the series; part of this current is shunted about each lamp, the resistance of the shunt being so proportioned that all of the current necessary for the lamp will pass through it. In addition to this resistance, an auxiliary resistance-reducer is provided which still further reduces the resistance to the line-current upon the rupture of the lamp-filament, or the cutting of the lamp out of circuit. This auxiliary resistance is cut out or reduced by the action of the heat produced by the heavy duty upon the shunt when the lamp is cut out.

When the shunt is unduly heated by too great a flow of current, a column of mercury in a tube about which the shunt is wound, is made to expand by the heat of the overloaded wire, and completes an auxiliary circuit, thus lowering the resistance of the shunt as a whole, and completely shunting the lamp.

VARLEY'S ELECTRIC CONTACT PROTECTOR.

Great difficulty is frequently experienced in the electrical operation of call bells, in consequence of particles of dust or other foreign substances getting in between the contact points, and the risk of the alarm becoming inoperative is augmented by the fact that considerable periods of time often elapse during which the call is not in use.

In order to obviate this, Mr. Richard Varley, Jr., of Englewood, N. J., electrician at the works of the Okonite Co., has invented the device shown in the accompanying illustrations. As will be seen, the contact A is in the form of a screw with a platinum plug, and the other contact B, is held by the spring attached to the armature.



Varley's Electric Contact Protector.

The protector E is made of thin sheet rubber that extends from one contact to the other, forming a dust-proof inclosure. This protector is made of two discs with a central opening in each, one fitting around the button head of the contact B, and the other around the end of the screw A. The discs are united at their edges and vulcanized, thus excluding all dust. Hence it is not necessary to enclose the bell or magnet in a case, as is sometimes done, to aid in keeping the bell in working order.

The protector can be similarly made for the contacts of a telegraph key, the contact studs having heads with annular channels or necks for the edges of the elastic discs.

THE COATING OF INCANDESCENT LAMP FILAMENTS.

The ordinary custom of coating the filaments of incandescent lamps with deposited carbon is open to some objections, from the fact that, carbon being a fairly good conductor, it is necessary either to make the filament exceedingly fine, with a sufficient protection of deposited carbon, or larger with an insufficient protection.

To overcome this difficulty, Messrs. Georg Erlwein and F. G. A. Heller, of Berlin, have invented a method of depositing a solid coating of incandescing material, consisting of the metallic carbides of various difficultly fusible metals. Owing to the smaller conductivity of these compounds, as compared with carbon, the coating may be made much thicker than that now in general use, admitting, therefore, of the use of thicker cores, and increasing the life of the lamp.

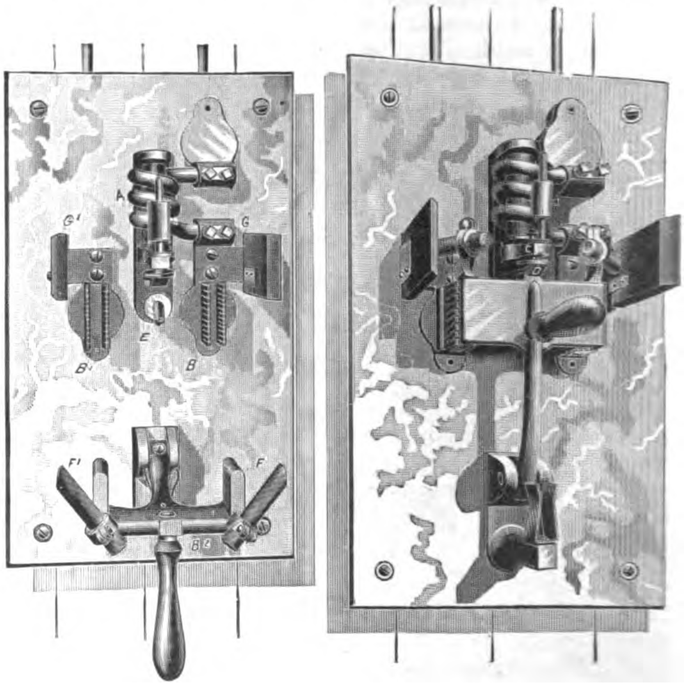
The method of deposition is as follows :

The metal or base of the carbide is deposited upon the carbon filament simultaneously with carbon from volatile metallic compounds in the presence of a hydro-carbon and hydrogen, or the carbon filaments, saturated with the easily-reducible compounds poor in oxygen, are heated to incandescence in an atmosphere of some hydro-carbon. The metals are reduced by the heat, and at the same time a deposit of carbon is made upon and among the particles of metal, or the metal may be reduced and the carbon deposited in any other way, and thus the reduced metals enriched with carbon. Among the metals suitable for this purpose are mentioned iron, chromium, and manganese.

THE WESTINGHOUSE AUTOMATIC CIRCUIT BREAKER.

Street railway men who have operated street cars and have used in their station the ordinary fusible block, and the make-and-break switch, know how difficult it is to keep their switch-board looking well, especially when they have had a number of short circuits on the line. Not only are the safety-fuse blocks burned and discolored, but the portion of the switch-board near the safety-fuse is also injured, and in addition to the above, the jaws of the switch are partly melted or fused, and the whole presents anything but a neat appearance. In order to avoid this, the Westinghouse Electric and Manufacturing Co. have devised an automatic circuit breaker, which breaks the current automatically whenever there is a short circuit on the line, without burning or in any way disfiguring the breaker itself. It has been tested on as high a current as 900 amperes and 500 volts, or a total of 450,000 watts, without in any way affecting or burning the breaker.

The accompanying engraving, Fig. 1, is a view of the breaker when open, and Fig. 2 represents it closed. The circuit breaker consists of an electro-magnet, A, in series with a double break switch—B, B^1 and B^2. If a short circuit occurs on the line, the electro-magnet will attract its armature, C, and with it the trigger, D, which holds the switch closed, and thereby allows the spring, E, to throw the lever arm out of the contacts. This, however, does not yet open the circuit, as the carbon contacts, F and F^1, carried by the lever arm still touch the carbon plates, G and G^1, at the sides of the switch and at those carbon points the circuit is finally broken without injuring in the least the metal parts of the switch. The feeder switch should always be opened before the circuit breaker is closed again.



Figs. 1 and 2.—Westinghouse Automatic Circuit Breaker.

The point at which these circuit breakers will cut out, can be regulated by changing the weight, H, attached to armature. The Westinghouse Co. make two styles of circuit breakers, viz., one to work on feeders up to 400 amperes capacity, and one to work on feeders from 400 amperes to 800 amperes capacity.

AN INCANDESCENT LAMP FACTORY IN THE NORTHWEST.

BY

H. Norman Collins.

Among the new and important industries of the Northwest, a section of the country that has had an unprecedented and remarkably rapid growth during the past few years, is the incandescent lamp factory recently started by the Standard Lamp Company, of Appleton, Wisconsin. The new company is strongly backed financially and the field for its operations is very extensive, as evinced by the large volume of business already being done by the new concern, although of comparatively recent organization.

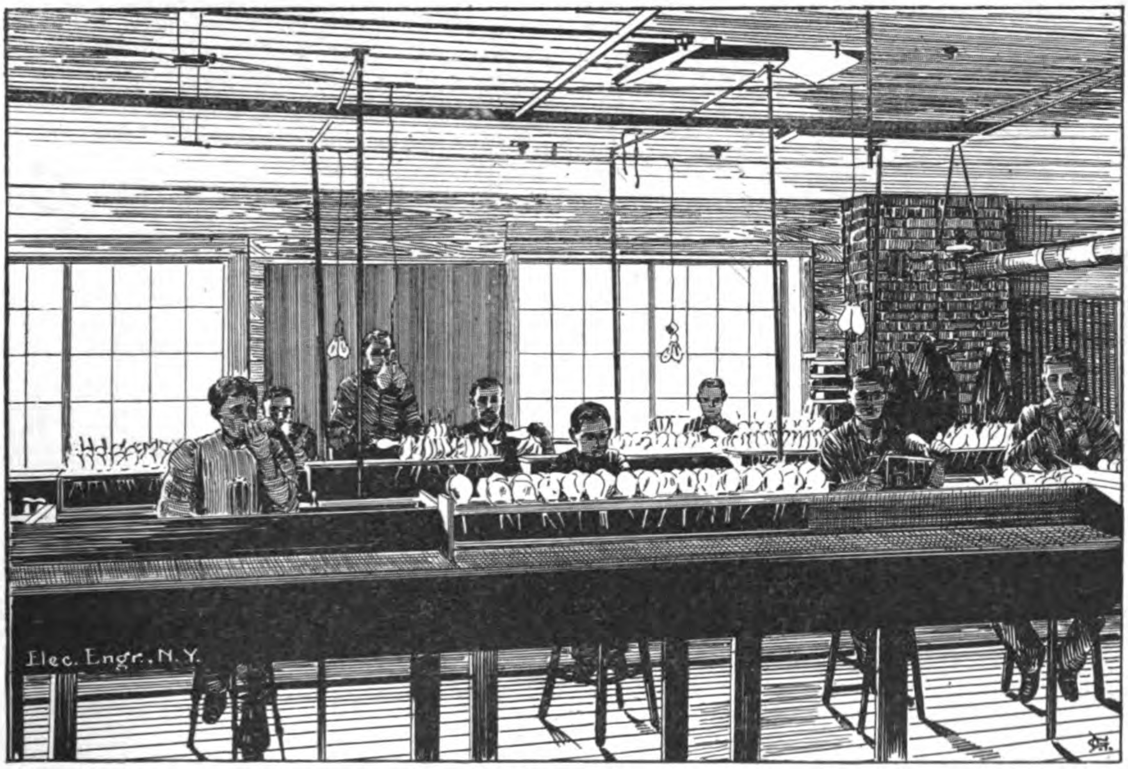
The writer having been cordially invited to inspect the new lamp industry has embodied his observations during a pleasant visit there in the following, which, it is hoped, will prove of interest and possibly instructive to those not versed in the process of incandescent lamp manufacture.

The factory of the company is located on the Fox river, on the lower dam, and comprises three buildings, the largest of which is 150 x 60 and three stories high, the others being somewhat smaller and only two stories in height. In the main building is located the dynamo room, and it is worthy of notice here that this factory is entirely operated by water power, being, probably, the only lamp factory so operated in the country. Five dynamos are employed, two each of 150 volts and 250 lights capacity, of the Mayo pattern, direct current; two of 500 volts and 50 amperes, used for treating purposes; and an alternating current machine of 500 volts and 50 amperes capacity, which is of special design and has been imported from Paris, and used for a special and improved method of treating the 50 volt lamps.

The water at present utilized is 225 h. p., obtained from three Leffel water wheels, which are controlled by a new electrical regulating device, designed by Messrs. A. F. & E. L. Oppermann, the electricians of the company. This apparatus maintains the power constant within a variation of one per cent. under all changes in load and enables the greatest uniformity to be obtained in the product. Another noticeable feature is an Archimedean screw for forcing the mercury into the pumps, dispensing altogether with the vacuum power pump.

The carbonizing room occupies all the remaining portion of the lower floor and is fitted up with specially designed furnaces for the carbonizing of the filaments.

On the next floor is the glass room, shown in the accompaning engraving, Fig. 1, in which the glass blowers are at work sealing in lamps and making pumps, etc. The pump room, Fig. 2, is also on this floor, and at present there are 120 pumps in operation. These are of a specially modified Sprengel type, adapted for obtaining the highest possible vacuum, and have several improvements over the ordinary Sprengel, being designed by Mr. W. H. Sauer, superintendent of the glass department, and whose efforts in this line are well known. The socketing and lamp base department is also on this floor.



Elec. Engr. N.Y.

Fig. 1.—Glass Blowing Department, Standard Lamp Factory.

The third floor is entirely devoted to the testing room, which is fitted up throughout with the necessary testing apparatus. For this department, Messrs. Queen & Co., of Philadelphia, are now engaged in manufacturing a new pattern photometer of the most delicate sensibility to meet the requirements of the constantly increasing business.

The treating department is provided for in the larger of the two other buildings and occupies both floors. This process is of a secret nature, but as the writer was courteously permitted to inspect this work, he had an opportunity to notice the extreme care and precision with which every portion of the work, down to the most minute details, is carried out, and he can say from practical demonstration that the toughness and homogeneity obtained by this process must necessarily be conducive to long life and high efficiency. Ten sets of treating apparatus are employed in this department and it is remarkable with what dispatch and facility the work is accomplished under this system. The greatest care has been taken to prevent danger from fire, and should one break out it will be met with an efficient system of grenades and portable fire engines.

The other two-story building, referred to above, is utilized as a warehouse and in it are stored a large stock of globes and raw material employed in an extensive manufacture of incandescent lamps.

It will no doubt be of considerable interest to give some details regarding the manufacture of these lamps, which the writer has had the privilege of carefully inspecting, from the raw material to the finished lamp. Commencing with the filament, which is made from a peculiar kind of silk thread expressly manufactured for this purpose, of an exceedingly close texture and of remarkable strength in proportion to its cross-section, the process of making a complete lamp is as follows : The silk thread is first subjected to a chemical treatment which destroys entirely the animal matter, leaving a structure of great density and strength, and possessing new properties, not heretofore inherent in the silk, which have the very desirable result of lengthening considerably the life of the filament and expunging those elements which usually cause blackening or discoloration after comparatively short use. This process, as far as the writer knows, is peculiar in its entirety to the Standard lamp.

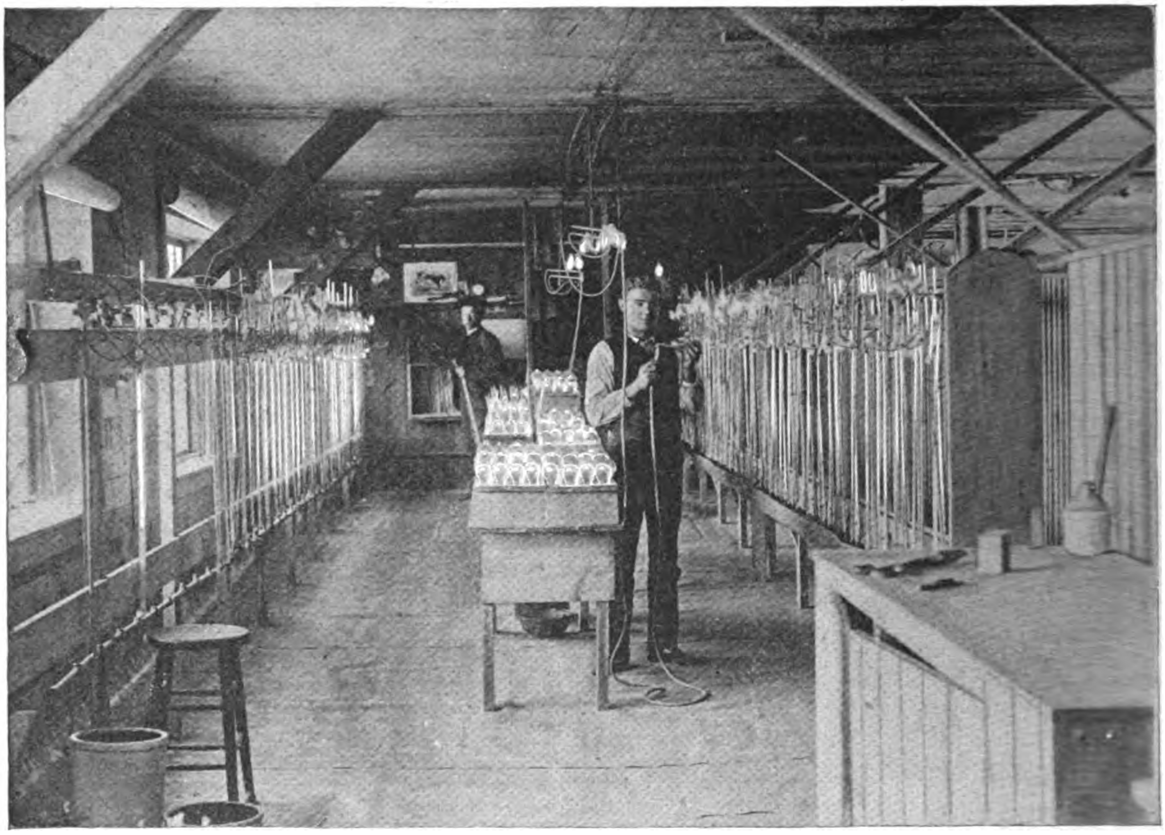


FIG. 2.—PUMP ROOM ; STANDARD LAMP FACTORY.

The next operation is to wind the chemically prepared fibres on to blocks of hard gas retort carbon of the shape and form of the intended filaments. This is effected by means of a winding machine which insures an even and equal tension and maintains the fibres evenly distributed upon the carbon-block forms. A binding thread is then wound around the blocks and fibres at right angles, thus holding them firmly in place upon the block, after which the bottom ends of the fibres are severed. The whole arrangement is then placed in the carbonizing retort among a number of others of similar character, all being embedded in a carbonaceous compound, and the retort is then placed in a special furnace and maintained at an even white heat which is carefully regulated and maintained for a number of hours.

After this baking process the fibrous filaments are taken from the crucible and removed from the carbon blocks and cut to the requisite length to give the desired resistance for the voltage required. They are now found to possess a very different appearance, having become transformed to a carbonized fibre of a highly homogeneous structure, possessing great hardness and resilience.

At this point it is necessary to digress somewhat and explain the *modus operandi* of preparing the stems in which the filaments are mounted. In the first place, the platinum wires for making connection between the filament inside the globe and the cap or lamp-base, are cut to the necessary length and their ends are then separately flattened out by means of a press and formed into minute tubes by passing them through a draw-plate. The wire is then given to the glass blowers, who bend it into a loop and insert it in a small glass tube which, in the manufacture of these lamps, is of a prepared black glass, which is found to make a closer union with the glass of the globe itself when joined together by fusion than if ordinary white glass is employed.

The small glass tube containing the platinum wires is then heated in the blowpipe flame and the ends of the wires having the small tubes in them are drawn apart, thus changing the stilt or stem from a round tube into a flattened V-shaped form with the wires intimately embedded therein, thus enabling an air-tight joint to be made with the globe.

We can now return to the filament which is mounted in the above described stem by inserting its ends in the tubes of the platinum wire formed to receive them, which are then compressed around the ends of the filament and the junctions electrically welded together, thus forming a perfect mechanical and electrical union between the two.

The mounted filament is now subjected to a further electrical treatment peculiar to this lamp, which gives to the filament the remarkable property claimed for it, of increasing in light-giving properties after the first 100 hours' run, instead of deteriorating, as is often the case.

The mounted filament is now complete and ready for inserting in the globe; but before this can be done, the globe itself must receive some attention. The globes are blown, in the case of the 16 c. p. lamps, and moulded, when required for larger size lamps, in a pear shape having a long neck of a width sufficient to allow of the insertion of the filament. The rounded portion of the globe is, at this stage, perfectly smooth, not having the small excresence or point seen on the completed lamp. The first thing to do is to "tubulate" the globe, for exhausting, which is accomplished by fusing a straight piece of glass tube about three inches long to the centre of the rounded portion of the globe, for the purpose of attaching the lamp to the mercury pump. The globe is now ready to receive the mounted filament. The platinum loop on the mount being first cut, so as to form two ends, the whole is then placed inside the globe, through the neck, which is thereupon heated and melted off at the required length, leaving the stem of the filament sealed to, and in the centre of, the neck of the globe. Copper wires are next attached to the platinum ends and the neck of the globe is again heated and the filament pushed down with the aid of the copper wires as far in the globe as desired, thus, so to speak, turning over a portion of the neck into the lamp.

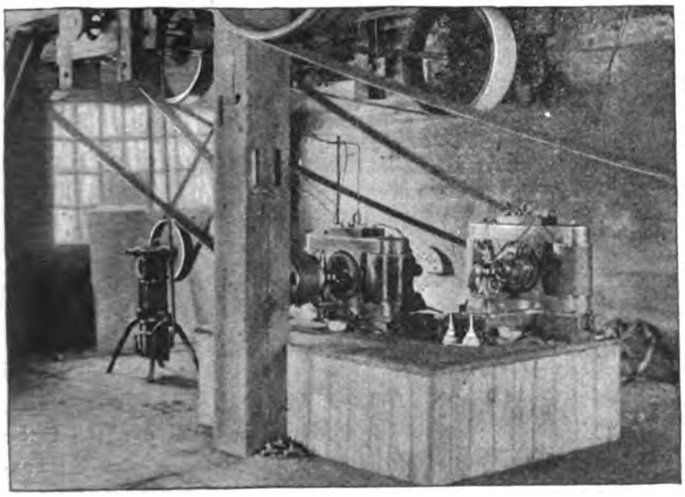

Fig 3.—Dynamo Room; Standard Lamp Factory.

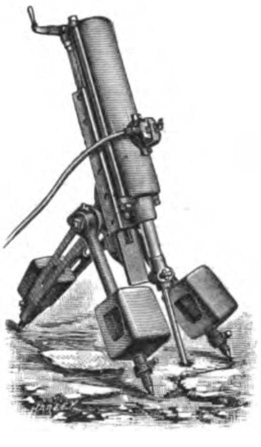
This completes the glass blower's work and the lamp is now given to the pumpers for exhaustion and is placed on the pump by means of the glass tube referred to above, and exhausted till a perfect vacuum is attained. This having been secured, the lamp is sealed off by means of a small blow pipe flame at the point of union of the glass tube and the rounded portion of the globe, leaving the familiar point or tip, above mentioned. All that now remains to do is to test the lamps for candle power and to detect the presence of any fault or defect in the lamp, should it exist, which is done by giving them a three hours' run, after which they are placed in the various kinds of lamp bases for use in sockets of different systems, sorted according to voltage, candle power and style of base, and placed in racks ready for packing and shipment.

This completes the necessary cycle of arrangements to be gone through in the production of what, when finished, appears to be such a simple piece of apparatus. It is unnecessary to state that throughout these processes the most delicate and pain's-taking care is taken to prevent the presence of any defect and produce for the market a highly efficient, durable and successful lamp. The whole manufacture of these lamps is conducted under the supervision of Messrs. Oppermann, to whose inventive genius the various special methods and devices used are due.

THE EDISON ELECTRIC PERCUSSION DRILL.



Edison Percussion Drill.

The Edison General Electric Company gave an exhibition of their electric percussion drill recently in Quincy, which was attended by a large number of quarry owners in Massachusetts, as well as by a large number of mine owners from Boston and Canada. The result of the exhibition was very satisfactory indeed, and the general opinion expressed by parties well versed in such matters was, that the electric percussion drill is far ahead of the steam or compressed air drill. Two steam drills, working in the same quarry gave an excellent chance for comparison.

Although the stone in Quincy is exceptionally hard, the electric percussion drill was able to drill a hole 1½ inches diameter, at an average rate of 2¾ inches per minute, with an expenditure of power less than 4 h. p. delivered to the generator. At one time the rate of drilling was as high as 4 inches per minute.

Among the special features brought out by this exhibition were the extreme ease with which the power could be transmitted to the drill from the generating station, and the great simplicity of the machine itself. The wires were taken from the edge of the quarry direct to the place where the drill was at work, without any further intermediate supports being needed. The distance along the wires was 350 feet, the vertical distance between the drill and the edge of the quarry, 100 feet.

For the purpose of exhibiting the ease with which the machine could be taken to pieces, and any defective parts replaced by others held in reserve, the drill was several times opened and entirely taken apart—the time required for this being less than three-quarters of an hour. It must be borne in mind that to do the same thing with a steam or compressed air drill, would require a very much longer time, owing to the fact that the different parts have to fit well together, and the joints have to be well packed. In case of accident to the last mentioned drills, they would have to be repaired by a competent mechanic, and it would be some time before they could again be used; whereas, with the electric drill, it was shown that any accident to any of its parts could be remedied within three-quarters of an hour by simply taking out a defective part and dropping in another one held in reserve, as the parts of the electric percussion drill are made according to standard sizes and are interchangeable.

LIGHTING THE "PRINCESS ALICE."

The electric lighting of H. S. H. the Prince of Monaco's yacht, "Princess Alice," has been placed in the hands of Woodhouse & Rawson United, Limited, Electrical and Mechanical Engineers, 88 Queen Victoria street, London. The engine is of the single cylinder vertical type running at from 200 to 250 revolutions per minute, according to the E. M. F. required, with a steam pressure of 150 lbs., and is provided with an extended bed plate for receiving the dynamo which is coupled direct to the engine, and gives, when running at 250 revs. per minute, current for 100-16 c.p. lamps at an E. M. F. of 135 volts, this particular E. M. F. being provided to allow of charging the accumulators. The number of lamps installed throughout the yacht will be about 100, the fittings being of an elaborate description, and designed especially for this installation. The whole of the arrangements are not yet completed, but in all probability there will be provided a set of accumulators, a projector, and also a powerful submarine arc lamp for carrying on scientific observations at night.

Mr. Wm. H. Cull, the superintendent and electrician of the Albany Railway, Albany, N. Y., has resigned his position to take effect May 1, 1891. Mr. Cull has had charge of the electrical department of this road since it began operations last April. In fact he constructed a large portion of it. It has been one of the most successful electrical railways in this country. Mr. Cull has, we understand, not yet made any engagement.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

Vol. XI. NEW YORK, APRIL 8, 1891. No. 158.

I have ever loved to dwell upon the very words in which great truths are given to the world, for thus the inspiration of the discoverer infuses itself insensibly into the soul of the reader, and leaves ineffaceable impressions of the simplicity, the dignity, and the comprehensiveness of science.—Alfred M. Mayer.

THE UTILIZATION OF WATER-POWERS.

VARIOUS articles in this issue bear upon the important question of the electrical utilization of water power. The leading contribution on the subject is the admirable paper read before the Buffalo Electrical Society, by Mr. Madison Buell, who has made a masterly compilation of the data of work in this line and presents his results in a most attractive and instructive form. Another article is that descriptive of the work proposed at Lauffen, on the Neckar, in the transmission of 300 h. p. A third article deals with the installation for the extensive utilization of water power electrically at Olympia, Wash., and a fourth gives some details of the work already begun at Joplin, Mo., where power and light are to be distributed over a wide area in a mining district.

It will be observed that Mr. Buell looks for the almost complete replacement of steam engines by turbines through the use of electricity. While we share many of his opinions and much of his enthusiasm on the task that water power has before it, we cannot go quite so far as he does. On the contrary, we believe that for an indefinite time to come the use of steam engines will increase. The engines will grow in size and, by compounding and condensing methods, be made more and more economical of fuel or water. The great change that does lie before us is that instead of having a large number of separate steam plants we shall have central steam plants whose power will be cheaply and effectively distributed through the agency of electricity. This process has already begun, and the extension of motor service has the beneficial effect also of making the production of current for lighting cheaper too.

In a word, the rapid increase in water-power plants will not greatly affect, or be affected by, the existence of steam plants. Any change that comes will not be in the direction of abolishing a single agency we now enjoy, but rather by way of limiting each to the work for which it possesses undeniable advantages of economy, efficiency and availability. Moreover, while the water-powers still to be brought under the yoke represent an enormous total waste, the net power utilizable will be but a fraction of the sum. Thus Niagara takes the drainage of an area of nearly 250,000 square miles, but it is only a small part of Niagara that even the most sanguine engineer expects to put in harness.

It seems well to make these remarks in passing, as it is often said by way of criticism, that electrical engineers in dealing with these questions are too fond of looking upon all the possibilites as actual achievements, and very slow to a admit the existence of any insurmountable difficulties. If this be a fault, it is at least a pardonable one, and certainly Mr. Buell has made a magnificent showing of hard, honest and successful work in this field, not only in America, but in Europe and other parts of the world.

As demonstrating the advanced state of the art of the electric transmission of water-power as compared with its condition less than ten years ago, we need only refer again to the experiments which have just concluded, and which constitute the preliminary tests of the transmission plant to be installed in connection with the Frankfort electrical exhibition to be held this year. It will be recalled that in 1882, Marcel Deprez carried out his famous experiment of transmitting the power of a waterfall at Miesbach to Munich, a distance of 37 miles. In that experiment, which is justly looked upon as the one which finally settled the question of the practicability of long distance power transmission, the potentials employed barely exceeded 1,800 volts, while the actual power obtained from the motor at the distant end did not exceed ½ h. p. We recall distinctly the objections raised at that time to the success of the system of transmission, among them being that of the inability of the armature to withstand successfully pressures exceeding very much the one employed. At that time, however, the alternating current had scarcely been hinted at, much less put in actual practice. To-day, however, the converter and alternating machine allow us to use potentials twenty times as great as that deemed safe only 10 years ago, by confining such high potentials to the outside circuits, and employing in the machine at the station the low tension current of conversion. Instead of ½ h. p. transmitted for 37 miles, it is contemplated to transmit 300 h. p. over 115 miles, and over a wire ⅙ of an inch in diameter, and at a potential of 30,000 volts. With these new methods at our command, the problem of economic transmission of water-powers takes on an entirely new complexion, and where once the cost of conductors acted as a deterrent to the undertaking of such work, the present methods relegate their consideration to an inferior position. The success of the proposed plant at Frankfort would, we are certain, open up a new era in electric power transmission for long distances, and at last lead to the realization of the predictions made 10 years ago, that not only Niagara but every other available water-power would be utilized through the medium of electricity.

STATISTICS OF THE TELEPHONE INDUSTRY.

THE annual report of the American Bell Telephone Co. presented last week, and now summarised in our columns, shows a large and steady growth in the industry. The earnings during 1890 reached the substantial figure of $4,375,290 as compared with a little over $4,000,000 in 1889. Out of this sum, not less than $2,213,913 was paid out in regular and extra dividends, representing the earning and profit yielding capacity of the capital stock of $12,500,000; while the large amount of $600,000 was carried to reserve for general depreciation, and an additional $55,500 for depreciation on instruments.

The other data contained in the report shows 483,790 instruments under rental, a gain of nearly 40,000 over 1889, while the number of connections reached 450,000,000, or about 3 per day per subscriber. It goes without saying that the return of wire mileage indicates a large addition to the number of underground circuits, for the telephone people have been most exemplary in their endeavor to meet the popular will in this difficult matter. The company through its Long Distance sub-organization has also been able to make remarkable progress in connecting together the various telephonic centres and systems; and its highly intelligent and creditable work in this new department is already bearing good fruit, not only in securing dividends on the investment but in giving increased facilities of communication to the public.

Such a report as that above referred to is likely to add to the unusual interest now attaching to the telephone situation, and its imposing totals of earnings and profits will make many mouths water. It is needless to point out that in a year or two this great system, built up with so much care and effort and ability, may be subjected to considerable strain. The figures indicate, however, a strength of organization and powers of endurance that bid defiance to assault, even if there were not left a single patent as a bulwark of protection.

BRIDGING TELEPHONE BELLS.

ALTHOUGH we have already described, in a general way, the important improvements introduced by Mr. J. J. Carty, in connection with telephone lines to which a number of subscribers are connected, the issuance of a patent on this valuable invention now permits us to give in detail the arrangements adopted. Mr. Carty's improvement, it will be noted, is one the very simplicity of which is its most striking feature. In its nature, indeed, it resembles very much the radical difference which exists between the operation of lamps in series and in parallel. In the one case we have the resistance in the line, as well as the retardation, equal to the sum of all the bells and transmitters in the line, while by bridging all the bells as shunts around the transmitters, not only is their resistance practically eliminated, but their retarding effect is also cut down to a very large extent. This has been sufficiently demonstrated by actual practice. The far reaching nature of this invention is not only due to the fact that it improves the quality of telephonic transmission, but also makes it possible to reduce the number of lines required for telephonic work, as in a number of cases a calling circuit has been necessary to avoid the evil effects experienced in operation. It is not improbable that Mr. Carty's system will become general for telephone service, both local and long distance.

ALTERNATE CURRENT WORKING.

AMONG the many valuable hints and suggestions contained in Mr. James Swinburne's paper, which we conclude in this issue, are several that just at the present moment are deserving of special attention. It seems to us that the mode of distribution, now in vogue, of supplying the high potential direct to the distributing conductors from machines delivering high E. M. F., is certainly open to objections, as pointed out by Mr. Swinburne. There appears to be no good reason why low potential machines should not be employed in connection with station transformers so that the high tensions are confined entirely to the outside circuits. This arrangement, it will be noted, has been adopted in the power proposed transmission between Lauffen and Frankfort, which we describe elsewhere in this issue. In the latter case it was considered more as a method of economy and safety in operating the alternating generators. But in a city distributing system, another more important factor enters into the calculation, namely, the greater economy of distribution to the district directly surrounding the station. Evidently, there is no advantage in employing converters where direct distribution can be economically carried out; hence, with low tension machines at the station which could supply current for short distances direct, or through converters for greater distances, uniformity in apparatus and economy can, we think be obtained, notwithstanding the introduction of an additional conversion in the latter case.

Mr. Swinburne also favors, and for good reasons, the method of distributing to local districts from single large transformers feeding low tension mains, instead of supplying each house with its own transformers. The important part also which the condenser may yet play in alternate current distribution makes it worth the while of inventors and experimenters to work in the direction of obtaining a cheap and durable type of this apparatus.

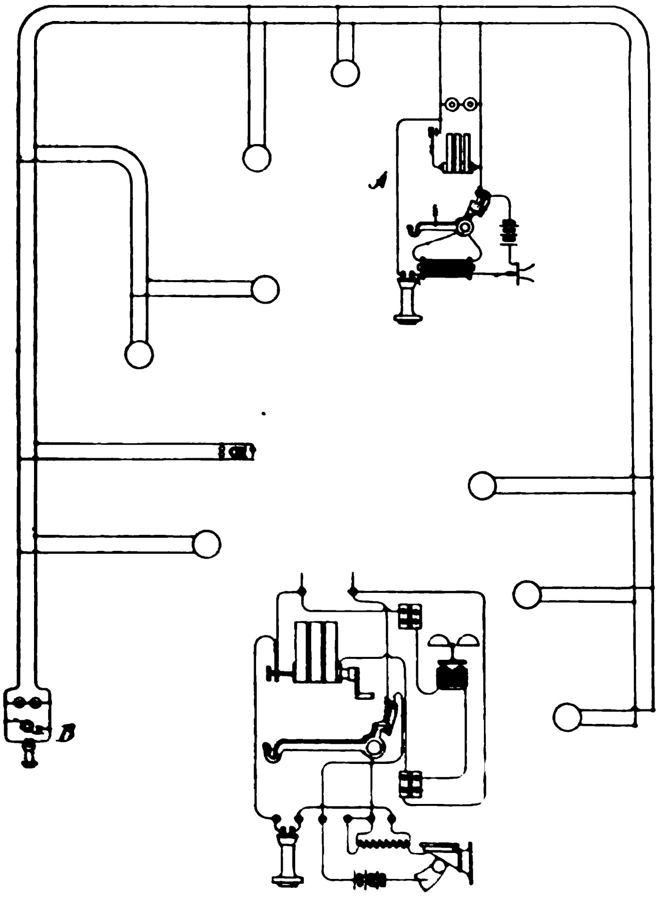
A Dust Proof Contact.

OF the many annoyances which the electrician is subjected to in the operation of the instruments and apparatus which he employs, that caused by the accumulation of dust is probable the most general and ever present. A simple device, therefore, to obviate this inconvenience will be recognized as a valuable adjunct to not a few electrical appliances, and as such the simple little protector designed by Mr. Richard Varley, Jr., and described in another column will be noted with interest. By enclosing the contacts in a dust proof flexible case, the inventor excludes dust and moisture without interfering with the motion of the contacts.

CARTY'S "BRIDGING BELLS" FOR TELEPHONES.

No better evidence of the efforts which are constantly being made by the telephone companies of this country, to improve and extend the usefulness of the telephone can be found, than the important advances which have recently been made by the men engaged in the technical branch of the business. We have at various times referred to the "Bridging Bell" system of Mr. J. J. Carty, which has come into extensive use since the last Telephone Convention, and are now enabled to give more complete details of this remarkably simple and effective arrangement, which has just been patented to Mr. Carty. By this arrangement it is now possible to connect a large number of subscribers to a single circuit without interfering with the clearness of the articulation.

Mr. Carty's arrangement is illustrated in the accompanying diagram, Fig. 1, which shows a metallic circuit line containing eleven stations connected in multiple arc. At A is shown in detail the connections of a station, and at B is a schematic representation of a station circuit when the telephone is off the hook.



FIGS. 1 AND 2.—CARTY'S BRIDGING BELL ARRANGEMENT.

Fig. 2 represents in detail the circuits of the bell, which are probably the simplest which have yet devised. The magnet coils are permanently connected to line and the lower contact of the automatic hook is entirely dispensed with. This bell is applicable alike to grounded and metallic circuits and is in successful use on both classes of lines.

Apart from a number of mechanical improvements and general superiority of design, the distinctive feature of this bell is the putting of each bell magnet in multiple arc with its own generator instead of in series with it, as has heretofore been the case. The bell magnet itself is of high inductance, and is so designed as to be absolutely without any bad effect on the telephone current.

The "bridging bell" possesses so many points of superiority that there is little doubt that it will replace all other kinds at an early day.

THE ELECTRICAL UTILIZATION OF WATER POWER.[1]

BY MADISON BUELL.

THE paper began with an eloquent account of the formation of water in the early days of the world's existence, and showed how at least three-quarters of the surface of the globe are covered with it, part of it being kept in motion by the tides and part through the agency of clouds and springs. These two forces embodied in water, Mr. Buell said, would eventually dispense with the burning of coal for power and crowd the steam engine out of employment. "The energy of the tidal wave, the rapid river, and mighty cataracts transformed into electrical energy is a branch of electrical science that is going to revolutionize the industries of the world."

As to the power represented in the flow of water, Mr. Buell pointed out that not less than 21,446,210 cubic feet pass over the lip of Niagara every minute, while the flowing of nine rivers that empty into the Pacific, represents 900,000,000 h. p. every time it descends one foot. On the other hand, the United States has steam engines representing 7,500,000 h. p.; England, 7,000,000; Germany, 4,500,000; France, 3,000,000; and Austro-Hungary, 1,500,000. These figures do not include the 3,000,000 h. p. of 105,000 locomotives. Add this to the other motive power, and it will be found, remarked Mr. Buell, that we have on this globe, engines equal to 46,000,000 h. p. These engines do the work of 1,000,000,000 men, or twice the working population of the earth. It is the place of water power utilized electrically to supplement and replace these engines, and it would therefore be worth while to see how far the revolution has already gone.

Mr. Buell with the aid of an imaginary camera then took his audience through a picture gallery of electrical water power plants.

"Let us press the button, and see what the camera reveals. The negative is clear and well defined. The picture is an inspiring one and full of grand significance, to an electrical engineer. It shows that the ethereal vibrations of the sun, are melting the Alpine snows, and the water in a never failing stream is revolving the turbine wheels, which in its turn, whirl the dynamo armature, and its electrical energy is conveyed miles away over a copper thread to a motor of a woolen manufactory of over 36,000 spindles. Another movement of the ethereal camera, another pressure of the 'button' and we have another negative, showing hundreds of laborers erecting a large plant at Rheinfelder, on the Rhine, consisting of 20 turbine wheels coupled direct to dynamos of 500,000 watts. The energy is to be transmitted to various industrial centres within a radius of 15 miles.

"Here is one showing a recent achievement in modern engineering, in an electric mountain railway at Burgenstock, near Lucerne, Switzerland. The Burgenstock is almost perpendicular; from the shore of Lake Lucerne it is 1,330 feet, and it is 2,800 feet above the level of the sea. The total length of the road is nearly a mile, operated by two dynamos of 25 h. p., worked by a water wheel of 125 h. p.

"The next negative shows a peculiar view between Pazzala and Lugano, in Italy. At the right of the picture, we see a large waterfall, which supplies the water conducted through iron pipes to the dynamo room, where two Girard turbines of 300 h. p. each run two dynamos, one for continuous and the other for alternating currents, the former working the tramway motors, the latter supplying nearly 2,000 16 c. p. lamps at the hotel, and in private buildings. The tramway is a double track one of over a mile in length and is worked by a cable, supported on wooden rollers, one branch of the cable is attached to the ascending, and the other to the descending car.

"Here is a picture of the town of Trente, Austria. A large water-fall furnishes the power sufficient to supply electrical energy to all the mills, hotels, and small industries; it is also furnished to the houses of the poorest inhabitant of the town, not only power, but illumination. The next view is an Irish scene of the Giant's Causeway Electric Railway in the north of Ireland, showing 2 Alcott turbines driving dynamos which furnish power for the motors of the railway; the latter is eight miles long.

"The camera is full of splendid negatives, pictures mostly of electrical plants in Switzerland. Counting them, I find nearly 200 electrical power stations operated by water-power, and it would be too tedious to give full descriptions of each one, especially so, when I desire to take hurried views all over the world.

"The next picture represents a hotel 'The Bernina' at Samaden, Switzerland. It is lighted by electricity, the power being supplied by a waterfall some distance away. As the power is not required during the day for illumination, the current is utilized for cooking, by heating German silver resistance coils. The cooking operations for the hotel are all satisfactorily performed by this method. While I am putting in a new set of plates into the ethereal camera, I will say that it is a well-known fact that Switzerland is disadvantageously situated as a manufacturing country; although it is supplied with an almost unlimited number of the finest water powers in the world, situated upon unfailing streams, fed by the melting of Alpine snows, yet these are located in inaccessible valleys and ravines where economical transportation of heavy products is impossible. Railroad lines are in the main valleys at too great a distance from the water powers, to render them of much value. Steam power is expensive as there are no coal mines, and the coal must be brought many hundred miles up heavy grades. This is so costly that the Swiss manufacturers have been unable to compete with those more favorably situated in conntries in close proximity to the iron and coal districts. Swiss industries heretofore have been on this account confined to the lighter and more delicate varieties. The recent introduction of methods of transporting and distributing power by electricity is rapidly changing this state of affairs, and in a few years Switzerland will become one of the foremost countries of Europe in all grades of heavy machinery."

---

[1] Abstract of a paper read before the Buffalo Electrical Society, April 6, 1891.

"Even on the 'dark continent' the electrical energy sheds its ethereal light, for the first negative is an African view. It is the Forbes Reef Gold Mining Co. of Transvaal, South Africa. The primal source of power is a water-fall three miles from the mine, operating Pelton water wheels coupled direct to Edison dynamos, each dynamo having a capacity of 67 h. p. Over 200 h. p. is transmitted to a distance of four miles. The efficiency of the entire systems from the Pelton wheel pulleys, to the mining machine at the distance end is over 70 per cent. That is, over 70 per cent. of the energy delivered from the water wheel pulleys at the power station is given off at the motor pulleys for work. Another picture in South Africa reveals the fact, that the Kimberly Mines are also lighted and worked in the same manner."

"Selecting another plate, the scene is changed to Oregon. We have a splendid view of the falls at Willamette. The energy of the water is here converted into electrical energy, and transmitted a distance of 12 miles to Portland."

"A view in South America, shows a cataract of the Juncalillo River, having a fall of 600 feet, supplying water through steel pipes a mile to Juncal station, where it sets in motion 10 water wheels, each of 80 h. p., connected to dynamos, the energy of which is used in driving motors for boring through the Andes mountains, to provide for a new railway connecting the Argentine Republic with Chili."

"Now we have a view of Coronado Beach, Cal., where they are endeavoring to utilize the rotatory motion of the earth by converting the waves of the ocean into the motive power. The energy is transmitted through a cable, and experiments have demonstrated the entire practicability of the scheme."

"Here is another revelation. It is only one of the many forerunners that augurs success to the Niagara scheme. This is a a tunnel 16 feet by 12 feet and 2½ miles long, cut through the mountain from Feather River to Big Bend Tunnel Camp, Butte Co., California. A permanent dam built across the river just below the head of the tunnel diverts the whole stream into the tunnel, and a canal two miles long, extending from the other end of the tunnel, gives a fall of 800 feet, turning powerful Pelton water-wheels driving Edison dynamos. The working E. M. F. is 1,000 volts; the conductors are double metallic, and extend 18 miles, delivering electrical energy at 14 points in the circuit, where power is required for winding, pumping, etc. From 10 to 20 Sprague motors, varying from 5 to 50 h. p., are worked by branch conductors from these various stations, the potential varying at the motors from 500 to 700 volts."

"Steam in Nevada is expensive on account of the scarcity of fuel; water is also an expensive commodity, as in this case we see that it is brought from the summit of the Sierras, in pipes, a distance of thirty mile, to the Comstock mines. The Sutro Tunnel at this place affords an outlet for this water 1,700 feet below the surface of the earth. It is the utilization of this pressure that gives an illustration of an amazing exhibition of power. Six of the world renowned Pelton water-wheels are used for running the dynamos in a rocky chamber in the tunnel. From the dynamo room, wires are carried up to the motor room at the top of the shaft, there being a mile in each circuit. The water-wheels attached to the dynamos are 40 inches in diameter and run at 900 revolutions. They are made of phosphor-bronze in order to stand the enormous speed the velocity of the water would give them, when running without load, which would be 1800 revolutions, giving the periphery of the wheel a speed of 18,864 feet, or more than 8-½ miles a minute, the water flowing from the nozzle at a volocity of 19,260 feet a minute. You may get some idea of such force issuing from the nozzle of the pipes, when I state to you that I can see a group of visitors looking at them, with wonder expressed all over their faces, while one of the laborers in the mine wields powerful blows with a sledge hammer upon the stream of water, and the hammer rebounds as though the water were a bar of steel. The compact arrangement of combined dynamos and water-wheels, and the noiseless operation of the latter, make it almost impossible to realize the amount of power developed by the swiftly revolving armature."

"In Colorado there is water power enough to furnish light and power for the whole state. The thriving town of 7,000 inhabitants, Aspen, fairly vibrates with ethereal manifestations. Eight Pelton water-wheels running 1,000 revolutions, under a head of 820 feet, with a maximum of capacity of 174 h. p. each, aggregating some 1,400 h. p., revolve the armatures of as many dynamos, furnishing the current for 120 arc lights of 2,000 c. p. each, and 2,000, 16 c. p. incandescent lights. These lights are distributed over an area of over four square miles, and are used for lighting the streets of the town, hotels, stores and residences. Greenwood Springs is also in a blaze of electric light. Mills, pumps, hoists and tramways are successfully run miles away from the power station. During the winter months the Pelton wheels though incased in ice for weeks together, keep spinning away without cessation."

"The next negative gives evidence of the progress of the Japanese people. I can make out five water-wheels, having an aggregate capacity of nearly 600 h. p., running dynamos; the electrical energy being transmitted to the city of Kioto, for general manufacturing purposes. The water is conveyed to the wheels through 2,000 feet of sheet iron pipes, and the supply is obtained from the Kioto-Fu-Che canal."

"Views all over California and the Pacific region, show the progress already made in the transmission of electrical energy by means of water power. Away up on top of the mountains nestled in among the clouds, 2,000 feet above Red Cliff, in the very heart of Eagle River Canon, I behold the town of Gilman, more than 11,000 feet above the sea level. Looking across from Gilman on the other side of the great canon, there is a mountain stream called Fall River, rising in the mountain of the Holy Cross, and I can almost hear its roar, as it crashes and tumbles down and over the rocks and enters the Eagle River at the bottom of the cañon. This water is brought by a pipe line into the mines, and the fall is equal to 500 feet perpendicular, and its energy drives the dynamos, the electrical energy being conveyed to all parts of the richest mines of gold and silver in Colorado.

"Swinging the camera to the state of Maine, the eye takes in the great Penobscot river, the largest in Maine, draining over 7,400 square miles, a region as large as the state of Massachusetts, for 12 miles from Oldtown to Bangor the river falls over 90 feet, giving several of the finest water-powers in the world. At a place called Veazie, which I see is situated four miles above Bangor, there is an electrical plant in the course of construction, which, when completed, will be one of the largest in the world. Fifteen water-wheels of 150 h. p. each, will be placed in this plant, so arranged as to run separate or in groups. Six of the wheels are already in operation. The plant will supply lights and power for the cities of Bangor and Brewer. The water-power at Veazie is immense; the flow of the river at this point at low water. is 146,000 cubic feet per minute, affording 2,500 h. p. with a nine foot head. A portion of this negative shows the town of Dover on the Salmon Falls river, on the division line of the state of Maine and New Hampshire. Light and power are not only furnished to Dover, but to several distant towns. Power is also furnished to a street railway seven miles in length. The water-wheel has a capacity of 500 h. p.

"I find to the right of this negative a scene in the Commune of Millas, Western Pyrenees." It shows an area of 1,500 acres, devoted to wine-vintage. A stream of water furnishes power for lifting and driving purposes, driving dynamos and motors, and furnishing current for 200 incandescent lamps distributed in the houses within the area named. The length of wire used in connecting the various buildings in this system is 62 miles.

"Pointing the camera toward Lake Superior I see extensive preparations are being made to utilize the waters of that lake, which fall at the Sault, about 80 feet to the level of Lake Huron. The water-power at Sault Ste. Marie is estimated to have a velocity and volume of 122,000 feet per second, equivalent to 236,000 h. p. A tail race five miles long on the Canadian side and a canal five miles long on the American side are to be constructed. The canals will be each 1,000 feet wide, the widest in the world. Blast furnaces, shipyards, paper mills, pulp mills, flour mills and other industries will all be furnished."

Mr. Buell, then speaking of tidal power, said he saw no good reason why that of the East river, between New York and Brooklyn should not be utilized for the two cities. To show how vast is the energy of natural forces, Mr. Buell proposed to consider a storm traveling 60 miles an hour extending over 500 miles of country:

One of our storms exerted a pressure of 80 lbs. per square foot or ½ lb. per square inch, and traveled at the rate of sixty-six miles per hour. "There are in a square mile 27,878,400 square feet, or 4,014,489,000 square inches. If the pressure was half a mile in vertical height, we have for each mile in width of the track of the storm, an area of 2,007,244,800 square inches upon which the storm acted with a pressure of ½ lb. and with a speed of 5,800 feet per minute.

To find the horse-power we have the formula:

$$\frac{\text{Area in inches} \times \text{pressure in lbs.} \times \text{speed in feet per minute.}}{33{,}000.}$$

The calculation becomes:

$$\frac{2{,}007{,}244{,}800 \text{ square inches} \times \tfrac{1}{2} \text{ lb. pressure} \times 5{,}800 \text{ feet.}}{88{,}000.}$$

the result is 70,557,700 horse-power for each mile breadth of the storm.

To produce the same horse-power, with improved engines consuming but 2 lbs. of coal per hour per horse-power, would take 63,000 gross tons of coal.

Assuming the track of the storm to be 500 miles wide, the hourly consumption of coal to generate an equal power would be at least 31,500,000 gross tons, or one and a quarter times the annual product of the entire anthracite coal region.

Coming back to water-power Mr. Buell said:

"Upon the beautiful Spokane river I can see the city of Spokane Falls now one of the prominent cities of the West. In 1885, when the present city was a mere town of a few thousand inhabitants, there was a little wooden shed erected in which there was placed an electrical plant, capable of furnishing electrical energy for twelve arc lights and less than three hundred incandescents. One water-wheel furnished the power to run the dynamo and the whole affair had, up to a short time ago, a varied and checkered career. Now consider the contrast. The power I see in Spokane Falls, compared with the water-power so far developed in any country, is the peer of them all. As the development proceeds and its immense force made fully available, its financial value will be stupendous; to replace the power, which this negative shows, by steam, would constitute the outlay of $10,000 per day for fuel alone. An idea of its actual money value may be obtained, when it is stated that the cost of producing one horse-power per year by steam is $50, and the lowest total power available at Spokane Falls is 30,000, the amount of wealth annually added to that city on the basis of $50 a horse-power per year would be $1,500,000. The power station now seen at the same place where the little wooden shed stood in 1885, is one of the greatest in the world. It is estimated at three thousand horse-power and distributes electrical energy for 12,000 incandescent lights and 1,200 arc lights, besides furnishing it for nearly all classes of industries. No city in this country can show, for its size, so great an employment of electrical energy in everyday life.

"The experiment of transmitting three hundred horse-power electrically from Lauffen on the Neckar to the Frankfort exhibition, a distance of over 100 miles, will be tried the coming summer. The result of preliminary experiments already made, indicate that the proposed transmission will be a complete success. I have seen an electric arc light produced in Buffalo, where the energy to make such a light came from a point beyond Syracuse, N. Y., over a No. 8 galvanized iron wire, a distance of over a hundred and fifty miles."

Mr. Buell now came to a consideration of the great work proposed at Niagara Falls, and said:

"Let us now take a look at the present hydraulic canal, which even now is considered a work of great importance, though soon to be abandoned. It was constructed in 1855, and is, as you see, cut through solid rock across the peninsular on which the village is built. The canal is nearly a mile long, and was originally planned to be 100 feet wide and ten feet deep. This canal lay idle for nearly a quarter of a century, until one of our citizens opened up its immense facilities. In 1878 there was only one water-wheel on the canal, to-day we see a large number of buildings along the bank of the river using an aggregate of nearly 8,000 h. p. The Brush Electric Light and Power Co. furnish light not only for Niagara Falls, but for Suspension Bridge. The wires of the company also cross the river into Canada and light Niagara Falls, Ontario, making a circuit of several miles along the bank of the river on each side.

"The idea of the tunnel at Niagara Falls originated with the late Thomas Evershed. The tunnel or tail race is to extend from the surface of the water level below the Falls to a point on the Niagara river above the Falls. It is to be connected with the river by means of short surface canals, wheel pits and cross tunnels. The power expected to be produced by the capacity of the tunnel will be equal to the water-power of Lawrence, Lowell, Holyoke, Turner's Falls, Manchester, Bellow's Falls, Lewiston, Me., Oswego, Patterson, Augusta, Ga., Minneapolis, Rochester and Lockport combined. The method of using the power is the same as that in operation upon the Hydraulic Canal. Though the principle is the same, there is a difference in the manner of obtaining the water. At the Hydraulic Canal there is one long surface canal, a canal basin or reservoir, wheel pits and short tail races to the adjacent high bank of the river. In the case of the tunnel, the Niagara river is the basin or reservoir, directly connected by short surface canals, wheel pits and cross tunnels, with one great tunnel or tail race, nearly two miles in length, which carries the water from the wheels to the Niagara river below the Falls. The tunnel is to be of horseshoe shape, having a capacity equal to a circle of twenty-five feet in diameter, extending through the solid rock from the water level below the Falls to the upper river above the cataract, a distance of one mile. From this point the tunnel is to continue parallel with the shore of the river one and a half miles, at an average depth of 160 feet below ground and about 400 feet from the river, with which it is to be connected by means of surface conduits, through which the water from the river enters, and is drawn through the shafts and wheel pits into the great tunnel below. The plans adopted will develop 120,000 horse-power.

* * * * * * * * *

"Crossing now over the new bridge below the cataract into Ontario, we learn from reliable sources that the scheme for the electrical utilization of the Canadian Falls is well under way. The Pelton Water Wheel Company, of San Francisco, Cal. have sent to the Niagara Falls commission at London, England, an estimate of the wheels and appurtenances for one block of twenty thousand horse-power. For an electric section, four wheels to develop 8,000 horse-power; for a compressed air section, one wheel of 4,000 horse-power, and for the hydraulic or pumping section two wheels of 4,000 horse-power. The scheme, estimates and adaptation of Pelton wheels of such enormous power involved a mass of engineering work, creditable alike to all concerned in the labor.

"The Pelton wheel is what is termed a tangential wheel, and is considered of great simplicity of construction and efficiency. The diameter and consequent axial speed of tangential wheels, of the Pelton type are such as to adapt them to the requirements in any case, so that direct connection can be made to dynamos, etc. This method has been adapted by the Pelton Water Wheel Company in their plans for the Niagara plant, and the wheels are to suit present or future stipulations of the power company as to speed. The Pelton wheel employs round jets, impinging on peculiarly formed vanes, constituting marked advantages, it is claimed, over wheels of the Girard type. The wheels are not well known in the East, for the reason that the circumstances which led to their use and development in California do not exist elsewhere, *i. e.*, working heads of from 100 to 1,600 feet, and for the reason that every stream is torrential until it reaches the plains. The company furnishing the Pelton wheels, claim that they can arranging a system so that a wheel can be made to develop at pleasure 1,000 to 5,000 horse-power without impairing its relative efficiency, and that such changes can be made in a moment's time, and when the wheels are in operation. The two plans for the electrical utilization of the water of the Niagara, it will be seen are totally different. Mr. Ferranti, the engineer of the Power Company organized to erect works on the Canadian side of the river has a preference for the Pelton wheel and is investigating its merits. I am reliably informed that the London commissioners have given a prize premium to the Pelton Co., for their plans in connection with the Norwalk Compressor Co."

TRANSFORMER DISTRIBUTION.[1]

(*Concluded.*)

BY J. SWINBURNE.

A machine without friction may be imagined, and when its field magnets are separately excited, so as to give an electromotive force exactly equal to that of the mains when it is connected so as to be in step, it runs as a motor taking no current. At each instant the electromotive force of the machine is exactly equal to the electromotive force of the mains, so no current passes. On putting on some load the machine begins to lag. As soon as the machine lags, a current passes through the armature. The current due to the difference of two equal alternating electromotive forces is not in step with either of them. This is shown in Fig. 6, where two pressure curves are drawn a little out of step. The current through resistance is proportional to the shaded parts. If the electromotive force of the machine were still the same as that of the mains, it would still develop no power as a motor, because at some parts of the period it would be supplying power to the mains, and at other parts the mains would be supplying power to the armature; for at any instant the armature current would be equal to the difference of the two electromotive forces divided by the resistance of the armature. The average current curve is shown in Fig. 7. The electromotive force of the machine does not, however, remain equal to the main electromotive force, merely differing from it in phase, but is decreased by the reaction of the armature current on the field magnets. The average current curve shows that there would be considerable back induction, or many ampere turns tending to weaken the field. This weakening of the field by the armature reaction allows the main also to supply a current against the electromotive force of the machine, so that it acts as a motor, and power can be taken from it.

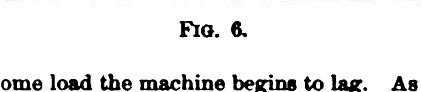


FIG. 6.

---

[1] Abstract of a paper read before the London Institute of Electrical Engineers.

If the machine is to be worked as a generator in parallel with the main circuit—that is to say, if it is to supply power to the mains instead of to take it from them—the same reasoning holds good. If the engine supplies just a little too much power, the machine will begin to lead, and an armature current will pass, which will strengthen the fields by reaction, and the machine will at some instants act as a generator, because its electromotive force is now a little higher, as the armature current has strengthened its field. Similarly, if the steam of the engine were completely shut off, the machine would lag until it worked as a motor.

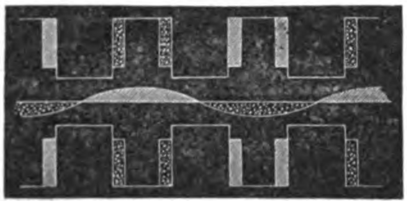

FIG. 7

According to the armature reaction theory, then, whether a machine will run in parallel with others depends on its armature resistance and armature reactions. It must be borne in mind that most machines have cast-iron fields, and though that may make no difference according to the orthodox theory, it does from the armature reaction point of view. If the field magnets do not quickly respond to the armature reactions, it may be difficult or impossible to run machines in parallel.

Another important consideration is the government of the engines. If two engines are working two machines in parallel at 200 revolutions, and one governor is set for 200 and the other for 195 revolutions—if the governors are truly isochronous, one engine and dynamo will supply the whole of the power, and the other will be dragged round idle. The whole question of the government of central stations requires the most careful consideration. I have dealt with the matter at some length elsewhere,[1] but the subject should be very fully thought out in designing stations.

ARRANGEMENT OF STATION.

If the machines are employed in parallel, they may feed into common bars, as in the case of direct currents. If each dirtrict must have its own circuit—which seems to be generally assumed necessary—each circuit may be led away from the common bars with a transformer regulator in it.

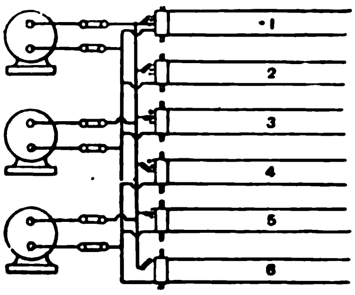

FIG. 8.

It is a great advantage to transform up, and to have all the switches, connections, and measuring instruments on the low-pressure side. The high-pressure circuits may then be arranged to have no metal exposed anywhere. If each district must have its separate circuit, it has its own step-up transformer, with its regulator.

One arrangement is shown in Fig. 8. The dynamos are all in parallel, and wound for 100 volts, the immediate neighborhood of the station being fed direct. Each feeder circuit has a transformer with a variable number of primary turns. A compensated voltmeter is placed on each, and all the attendant has to do is to alter the switches a little occasionally, so as to keep all the instruments' pointers vertical.

TRANSFORMERS.

The loss in the iron in transformers has until lately been very much overlooked; if it is even a small percentage of the full load of the transformer, it mounts up very seriously in station work when the transformers are in circuit all day and all night. The principle of the "Hedgehog" transformer is this: By using an open circuit the iron can be reduced in volume with a given induction. The mean length of the iron part of the magnetic circuit is considerably less, and more copper turns can be wound on without increasing this length much. The additional turns admit of a smaller cross section of core, so that the iron is enormously reduced. The loss in copper is somewhat increased; but, as the loss in copper is only serious at full load, this does not matter.

The exciting current, though larger than in the case of closed circuit transformers, is not a serious matter. The loss in copper is considerably smaller than the loss in iron in most closed-circuit transformers, and, as it varies as the square of the current, it is inappreciable except at full load, which very seldom occurs. The loss in iron is very small, so that the loss per day in ordinary working is very much smaller than in the case of closed-circuit transformers.

Perhaps the best way I can make this clear is by a comparison of actual transformers. As an average size of transformer, one taking 2,000 volts and a frequency of 100, and giving 15 amperes at 100 volts, may be taken, and the working compared.

A gun-metal casting forms the backbone of the transformer. It is cross shape in section, and at one end is spread out to form four legs. It also supports the lower flange, or cheek, of the winding. The four spaces have bundles of soft iron wire put in, so that the core is practically cylindrical. The cross-shaped core has been criticised on the ground that there are Foucault currents generated in it. The least consideration will show that there is no change of induction in it, and therefore no Foucault currents. The iron wire is bound tightly, and the two flanges are slipped into place. A gun-metal "spider" is then screwed to the top. It is finally held on by the eye-bolt, but temporarily a set screw is used. The core is then wound in a special lathe in the usual way. Both the terminal board and the coil flanges gave us a great deal of trouble till we found suitable materials. There is a great need of good insulating materials that will not warp, that will insulate perfectly, and that can be worked.

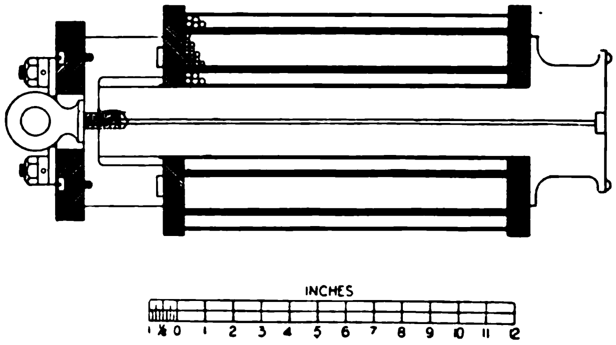

FIG. 9.

The electrical particulars of a 50 8 c. p. lamp transformer are as follows:—

Core, 13.5 in. long, 2.5 in. diameter. In taking the area of the core, allowance must be made for the space occupied by the backbone, and for the loss of room in using round wires. Maximum induction, 4,800. Loss of power in iron, assuming it to be of good quality, 13.5 watts. Primary, 3,920 turns of copper wire, 0.042 in. diameter; resistance, 37 ohms (warm). Secondary, 200 turns, 19/0.042 in.; resistance, 0.098 ohm. Loss of power in primary at full load, due to the transformed current, 21 watts; loss due to the exciting current—0.3 ampere—which is always on, 3.6 watts; loss in secondary at full load, 22 watts. Efficiency at full load, 96.15.

This transformer is shown to scale in Figs. 9 and 10.

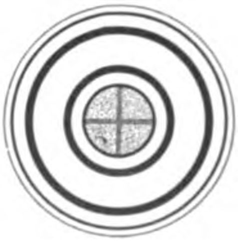

FIG. 10.

Fig. 11 is a scale drawing of a closed-circuit transformer I have taken as representative. The primary is 400 turns of 0.042 in. wire, and the secondary 20 turns of 0.176 in. The loss in copper at full load is 11.3 watts, and the loss in the iron 120 watts. At full load the efficiency is 91.95, or nearly 92 per cent. The diagram (Fig. 12) shows the percentage loss at various loads of the two transformers. The ordinates are percentage loss, and the abscissæ fractions of full load. Curve II. is the "Hedgehog," and IV. is the closed circuit. It will be noticed that the "Hedgehog's" efficiency increases slightly at first, and keeps above 95 per cent. till the load is reduced to one-fifth, and above 90 down to one-tenth load, and it then begins to fall more rapidly. The efficiency of the closed form, however, begins to fall at once, and falls rapidly. In house work the full-load efficiency is a matter of little or no consequence; the loss at very light loads is really important. A house that has a 50-light transformer is wired for 50 lamps, and that is the maximum load. As a rule, there are seldom more than 25 lamps on at any one time, and these are on during the evening only. The average load varies with the time of year and with the class of house. Shops, for instance, have full load for a short time each day; private houses have the lights in the hall and passages on the whole evening, with either the dining or drawing room, and for some time both the dining and drawing rooms are on. It will be a fair average if we take four hours of half-load per day as the output of house transformers. This means an efficiency of 83.3 per cent. for the "Hedgehog," and only 51 per cent. for the closed circuit. In other words, the waste in the closed circuit is between five and six times as great as in the open circuit.

---

[1] *Industries*, September, 1890.

There is thus no chance of iron being found good enough to allow the closed circuit form to compete with the open. There is one objection to the "Hedgehog" which must not be passed over, and that is the exciting current. The exciting current in the 50-lighter is 0.31; in the closed circuit it is 0.2; so that it is quite half as much again.

DISTRIBUTION.

Even with the most efficient transformers the house system is a very poor method of distribution. Apart from the question of loss of power, consider the outlay involved in providing each consumer with a high pressure double-pole fuse, a transformer, an automatic device for rendering the whole arrangement safe in case of insulation giving way, perhaps a double-pole main switch, a meter, and a fire-proof safe in which all these things have to be enclosed. In addition to this, it involves a complete high pressure parallel system of distribution, and a network of 2,000-volt underground mains, involving a heavy outlay, and probably heavy depreciation. There is no need for sub-stations; the low pressure network may be fed at various points by transformers and feeders coming direct from the station. These transformers need not be in houses or cellars; they can be placed conveniently in the ground in cases filled with insulating oil. At the station each feeder can be regulated, and has a compound wound voltmeter, so that an attendant can keep the pressure in the whole town constant. As Mr. Kapp pointed out in 1888, the advantage of such a system is enormous. In direct currents the low pressure mains must be large.

Even in scattered districts it would generally pay to use small low pressure mains and feeders. The alternate system has so many advantages over the direct in the matters of regulation and distribution when worked on the low pressure system, that it is astonishing that such arrangements are not utilized. For instance, with direct currents it is most difficult to find a leak; and one leak on the positive at the west end, combined with one leak on the negative at the east, will cause serious trouble. With alternate currents, a number of small local networks may be used, each of them being complete in itself. It is not in metallic connection with any other part of the town, nor with the central station. Where it meets the network of the neighboring district it is not metallically joined, as in the case of direct currents, but connected through a one-to-one transformer sunk in the ground, in a case full of oil.

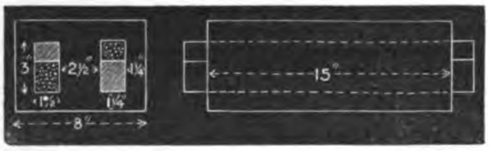

FIG. 11.

After the clear and able manner in which Mr. Kapp urged the advantages of low pressure networks for alternating currents, it is most astonishing that engineers should go on with house transformers. At present, however, we are using alternating currents in just about the worst way that could be possibly devised.

CONDENSERS.

Condensers may have a very large opening in connection with ordinary alternate-current distribution. Take the case of arc lamps. For instance, suppose a station supplies a 100-volt secondary circuit by means of transformers with 2,000 volts primary pressure; and suppose there are 200 arc lamps, each taking 33 volts and 10 amperes, arranged on the 100-volt circuit, with a choking coil in series with each. Suppose, for simplicity, that there are no incandescent lamps in use. The arc lamps then take 2,000 amperes and 100 volts; but this does not amount to more than 66,000 watts, as the current is not in step with the electromotive force. **The dynamos thus have to supply 2,000 volts and 100 amperes; whereas the same power, if the current did not lag, would be supplied by 2,000 volts and 33 amperes. This gives rise to several troubles. Suppose each machine has an armature wound to give 2,000 volts and 33 amperes, or 66,000 watts, it takes three instead of one to work the lamps. In addition to this, the lagging of the current weakens the field of the dynamos, so that they need more excitation to give 2,000 volts than they would need even on full load on a non-inductive resistance. Moreover, running three engines and dynamos at a third load instead of one at full load is not economical. A condenser takes a current which leads relatively to the pressure, so that it counteracts the effect of the lagging current. The 100 amperes may be regarded** as compounded of 33 amperes in step with the pressure, and 95 amperes lagging a quarter of a period. A condenser of about 85 microfarads will supply the 95 ampere component, while one dynamo supplies the 33 amperes really needed by the lamps. This reasoning holds good without the curve of sines assumption.

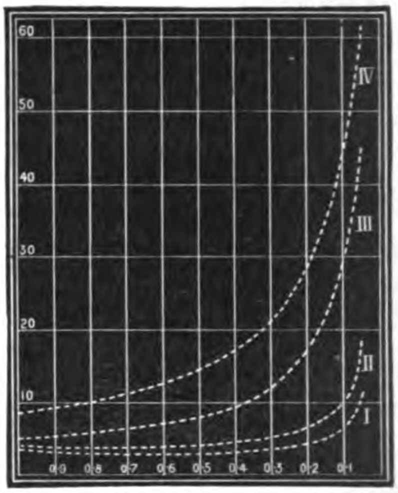

FIG. 12.

The use of condensers to overcome troubles arising from exciting or magnetizing currents of closed or open circuit transformers has already been mentioned.

The commercial manufacture of high pressure condensers is not easy, but it may now be said that it can be carried out.

Society and Club Notes.

BUFFALO ELECTRICAL SOCIETY.

At the meeting of the above Society on April 6, Mr. Madison Buell read a most able and interesting paper on "The Electrical Utilization of Water Power," of which we give an extended abstract elsewhere. At the close of his paper, Mr. Buell said:

"I thank you for the honor conferred in placing me in the chair of the vice-presidency of this society. In this connection it is a great pleasure to me to show you in what high estimation this society is held by the electrical papers of this country. We are all of us individually and collectively, more or less, indebted to them for the able and superior manner in which they spread out for our information all the great mass of electrical facts that are tumbling in so rapidly from all parts of the world. What has been said of "books" can be more fitly said of all of our electrical papers, "there is hardly anything more pleasant than speaking of them, and communicating to the public, the richness of thought that we have acquired" by their perusal. Mr. T. C. Martin of THE ELECTRICAL ENGINEER says:

"As regards the Buffalo Electrical Society, it has always been a matter of surprise to me that its work is so continuous and so good."

"Its success shows a very general interest in electrical progress and prosperity among those who might reasonably plead preoccupation and the pressure of daily duties." We must remember that the "productions of the press, fast as steam can make and carry them, go abroad through all the land, silent as snowflakes, but potent as thunder. It is an additional tongue of steam and lightning, by which man speaks." The individual members of this society as well as the society as a body, gain nine tenths of their electrical information from THE ELECTRICAL ENGINEER and its contemporaries, and through them the society is well and honorably known throughout the world. Investment in the electrical papers of the present day is a perpetual source of income. Benjamin Franklin truly said, "if a man empties his purse into his head, no man can take it away from him."

Letters to the Editor.

PHENOMENA OF CURRENTS OF HIGH FREQUENCY.

I cannot pass without comment the note of Prof. Thomson in your issue of April 1, although I dislike very much to engage in a prolonged controversy. I would gladly let Prof. Thomson have the last word, were it not that some of his statements render a reply from me necessary.

I did not mean to imply that, whatever work Prof. Thomson has done in alternating currents of very high frequency, he had done subsequent to his letter published in the *Electrician*. I thought it possible, and even probable, that he had made his experiments some time before, and my statement in regard to this was meant in this general way. It is more than probable that quite a number of experimenters have built such machines and observed effects similar to those described by Prof. Thomson. It is doubtful, however, whether, in the absence of any publication on this subject, the luminous phenomena described by me have been observed by others, the more so, as very few would be likely to go to the trouble I did, and I would myself not have done so had I not had beforehand the firm conviction, gained from the study of the works of the most advanced thinkers, that I would obtain the results sought for. Now, that I have indicated the direction, many will probably follow, and for this very purpose I have shown some of the results I have reached.

Prof. Thomson states decisively in regard to experiments with the incandescent lamp bulb and the filament mounted on a single wire, that he cannot agree with me at all that conduction through the glass has anything to do with the phenomenon observed. He mentions the well-known fact that an incandescent lamp acts as a Leyden jar and says that "if conduction through the glass were a possibility this action could not occur." I think I may confidently assert that very few electricians will share this view. For the possibility of the condenser effect taking place it is only necessary that the rate at which the charges can equalize through the glass by conduction should be somewhat below the rate at which they are stored.

Prof. Thomson seems to think that conduction through the glass is an impossibility. Has he then never measured insulation resistance, and has he then not measured it by means of a conduction current? Does he think that there *is* such a thing as a perfect non-conductor among the bodies we are able to perceive? Does he *not* think that as regards conductivity there can be question only of degree? If glass were a perfect non-conductor, how could we account for the leakage of a glass condenser when subjected to steady differences of potential?

While not directly connected with the present controversy, I would here point out that there exists a popular error in regard to the properties of dielectric bodies. Many electricians frequently confound the theoretical dielectric of Maxwell with the dielectric bodies in use. They do not stop to think that the only perfect dielectric is ether, and that all other bodies, the existence of which is known to us, must be conductors, judging from their physical properties.

My statement that conduction is concerned to some, although perhaps negligible, extent in the experiment above described was, however, made not only on account of the fact that all bodies conduct more or less, but principally on account of the heating of the glass during the experiment. Prof. Thomson seems to overlook the fact that the insulating power of glass diminishes enormously with the increase in temperature, so much so, that melted glass is comparatively an excellent conductor. I have, moreover, stated in my first reply to Prof. Thomson in your issue of March 18, that the same experiment can be performed by means of an unvarying difference of potential. In this case it must be assumed that some such process as conduction through the glass takes place, and all the more as it is possible to show by experiment, that with a sufficiently high steady difference of potential, enough current can be passed through the glass of a condenser with mercury coating to light up a Geissler tube joined in series with the condenser. When the potential is alternating, the condenser action comes in and conduction becomes insignificant, and the more so, the greater the rate of alternation or change per unit of time. Nevertheless, in my opinion, conduction must always exist, especially if the glass is hot, though it may be negligible with very high frequencies.

Prof. Thomson states, further, that from his point of view I have misunderstood his statement about the limit of audition. He says that 10,000 to 20,000 alternations correspond to 5,000 to 10,000 complete waves of sound. In my first reply to Prof. Thomson's remarks (in your issue of March 18,) I avoided pointing out directly that Prof. Thomson was mistaken, but now I see no way out of it. Prof. Thomson will pardon me if I call his attention to the fact he seems to disregard, namely, that 10,000 to 20,000 alternations of current in an arc—which was the subject under discussion—do not mean 5,000 to 10,000, but 10,000 to 20,000 *complete waves of sound.*

He says that I have adopted or suggested as the limit of audition 10,000 waves per second, but I have neither adopted nor suggested it. Prof. Thomson states that I have been working with 5,000 to 10,000 complete waves, while I have nowhere made any such statement. He says that this would be working below the limit of audition, and cites as an argument that at the Central High School, in Philadelphia, he has heard 20,000 waves per second; but he wholly overlooks a point on which I have dwelt at some length, namely, that the limit of audition of an arc is something entirely different from the limit of audition in general.

Prof. Thomson further states, in reply to some of my views expressed in regard to the constant current machines that five or six years ago it occurred to him to try the construction of a dynamo for constant current, in which "the armature coils were of a highly efficient type, that is, of comparatively short wire length for the voltage and moving in a dense magnetic field." Exteriorly to the coils and to the field he had placed in the circuit of each coil an impedance coil which consisted of an iron core wound with a considerable length of wire and connected directly in circuit with the armature coil. He thus obtained, he thought, "the property of considerable self-induction along with efficient current generation." Prof. Thomson says he expected "that possibly the effects would be very much the same as those obtainable from the regularly constructed apparatus." But he was disappointed, he adds. With all the consideration due to Prof. Thomson, I would say that, to expect a good result from such a combination, was rather sanguine. Earth is not farther from Heaven than this arrangement is from one, in which there would be a length of wire, sufficient to give the same self-induction, wound on the armature and utilized to produce useful E. M. F., instead of doing just the opposite, let alone the loss in the iron cores. But it is, of course, only fair to remember that this experiment was performed five or six years ago, when even the foremost electricians lacked the necessary information in these and other matters.

Prof. Thomson seems to think that self-induction wipes out the periodical undulations of current. Now self-induction does not produce any such effect, but, if anything, it renders the undulation more pronounced. This is self-evident. Let us insert a self-induction coil in a circuit traversed by an undulating current and see what happens. During the period of the greatest rate of change, when the current has a small value, the self-induction opposes more than during the time of the small rate of change when the current is at, or near, its maximum value. The consequence is, that with the same frequency the maximum value of the current becomes the greater, the greater the self-induction. As the sound in a telephone depends only on the maximum value, it is clear that self-induction is the very thing required in a telephone circuit. The larger the self-induction, the louder and clearer the speech, provided the same current is passed through the circuit. I have had ample opportunity to study this subject during my telephone experience of several years. As regard the fact that a self-induction coil in series with a telephone diminishes the loudness of the sound, Prof. Thomson seems to overlook the fact that this effect is wholly due to the impedance of the coil, *i. e.*, to its property of diminishing the *current strength.* But while the current strength is diminished the undulation is rendered only more pronounced. Obviously, when comparisons are made they must be made with the same current.

In an arc machine, such as that of Prof. Thomson's, the effect is different. There, one has to deal with a make and break. There are then two induced currents, one in the opposite, the other in the same direction with the main current. If the function of the mechanism be the same whether a self-induction coil be present or not, the undulations could not possibly be wiped out. But Prof. Thomson seems, likewise, to forget that the effect is wholly due to the defect of the commutator; namely, the induced current of the break, which is of the same direction with the main current and of great intensity, when large self-induction is present, simply bridges the adjacent commutator segments, or, if not entirely so, at least shortens the interval during which the circuit is open and thus reduces the undulation.

In regard to the improvement in the feeding of the lamps by vibrations or undulations, Prof. Thomson expresses a decisive opinion. He now says that the vibrations *must* improve the feeding of a clock-work lamp. He says that I "contented myself by simply saying," that I cannot agree with him on that point.

Now, *saying it*, is not the only thing I did. I have passed many a night watching a lamp feed, and I leave it to any skilled experimenter to investigate whether my statements are correct. My opinion is, that a clock-work lamp, that is, a lamp in which the descent of the carbon is regulated not by a clutch or friction mechanism, but by an escapement, cannot feed any more perfectly than tooth by tooth, which may be a movement of, say, $\frac{1}{32}$ of an inch or less. Such a lamp will feed in nearly the same manner whether the current be perfectly smooth or undulating, providing the conditions of the circuit are otherwise stable. If there is any advantage, I think it would be in the use of a smooth current, for, with an undulating current, the lamp is likely to miss some time and feed by more than one tooth. But in a lamp in which the descent of the carbon is regulated by friction mechanism, an indulating current of the proper number of undulations per second will always give a better result. Of course, to realize fully the benefits of the undulating current the release ought to be effected independently of the up-and-down movement I have pointed out before.

In regard to the physiological effects, Prof. Thomson says, that in such a comparatively poor conductive material as animal tissue the distribution of current cannot be governed by self-induction to any appreciable extent, but he does not consider the two-fold effect of the large cross-section, pointed out by Sir William Thomson. As the resistance of the body to such currents is low, we must assume either condenser action or induction of currents in the body.

NIKOLA TESLA.

NEW YORK, April 4, 1891.

Literature.

The Elements of Dynamic Electricity and Magnetism: By Philip Atkinson, A. M., Ph. D. New York: *D. Van Nostrand Co.*, 1891. 5x8 inches; 405 pages. Price, $2.

While there is no lack of books on the elements of electricity and magnetism, there has of late arisen a demand for a class of works which shall be adapted not only to the learner who desires to continue his studies with special reference to their future application in actual work, but also for that large class which has come to take a lively interest in electrical work, because it has been so forcibly brought to public attention during the last few years. A book to interest these learners and general readers, therefore, must present the subjects in their plainest dress, and must convey the facts through the medium of conclusive inductive reasoning rather than by the aid of formulæ. It is from this standpoint that the author has treated the subject matter contained in the book, which forms a companion work to that previously published, entitled "Elements of Static Electricity." In the present work the author has taken up the subject of dynamo electricity and magnetism, and very properly begins with definitions and a description of the voltaic battery. He describes the principal single and double fluid cells now in common use, and their method of operation. Two chapters on magnetism and electro-magnetism discuss the wide range of these phenomena. The author leads up from the natural magnet to the mariner's and surveyor's compass and gives one of the most complete short exposés of terrestrial magnetism that has come under our observation. He also discusses the form of magnets, and their polar attraction and repulsion. Passing on to electro-magnetism, we find a treatment of the laws governing the relation between currents carried in neighboring conductors and the effects of currents upon magnets and upon masses of iron. The author explains very clearly the simple rules by which all these phenomena may be remembered, and shows their application to the construction of the Ruhmkorff coil, which is described very fully.

Chapter VI is devoted to electric measurement. In it are described the various electrical units employed in practical electrical work, and this is followed by a description of the most generally employed testing instruments, among them the Thomson galvanometer, the Weston voltmeter, the Wirt voltmeter, the Cardew and others. The dynamo and motor are then taken up, and after a few short introductory paragraphs on the history of the dynamo, the author at once brings us to the types employed at the present time and their construction. This survey includes not only those of the well-known continuous current machines, but also the best known alternating current dynamos and motors. Thermo-magnetic motors are also touched upon here. Electrolysis and electric storage form the subject matter of the two following chapters, introduced by the theory of Grotthuss, which still seems to be the favorite one for text book purposes, and perhaps justly so. The application of the laws of electrolysis to electric storage is also pointed out, and the construction of the most recent types of secondary batteries is described and illustrated. The relations of electricity to heat form a chapter which will attract considerable interest as we find in it, besides the laws governing the generation of heat in conductors, a simple statement of electro-thermic phenomena and a description of the latest forms of the Thomson welding machine, and the results which have been obtained with it. The relation of electricity to light forms the subject matter of Chapter XI, in which the various phenomena of the effects of light on selenium are described, together with the magneto-optic polarization effects, and the various other photo-electric phenomena discovered by Becquerel, Kerr and others. The author then takes up the arc light and discusses its nature, and the most general types of lamps employed. This is followed by similar treatment of the incandescent lamp, in which connection the two and three wire systems of distribution are described. The telegraph and the telephone, to each of which a chapter is devoted, end the volume.

While we are not prepared to agree entirely with all the views expressed by the author, especially on points of theory, the present unsettled state of the latter might be easily made to account for divergences. If we may also be allowed to suggest, we think that the work in further editions, which will undoubtedly be called for, might be improved by a more rigid adherence to the classification of the subjects treated. The book has the undoubted merit of giving the latest information on the practical advances made, and does not burden the reader with a long and profitless review of what has been done during the last fifty years. The book is admirably printed and illustrated, and the author has evidently availed himself of the latest and best sources of information. We trust that the publishers will find their enterprise fully rewarded.

THE SWINBURNE TRANSFORMERS.

In my letter appearing in your last issue an error was made in the statement beginning; "In the communication from Mr. Swinburne a few days after the publishing of my article, Mr. Swinburne, etc." It should read as follows: "In a communication received from Messrs. Swinburne & Co. a few days after the publishing of my article, etc., they state that the leakage current in their transformers of 40 lights capacity is about 40 per cent.: allowing that this 40 per cent. is correct, the comparative leakage current in the open and closed types of transformers is approximately 10 to 1."

WM. STANLEY, JR.

PITTSFIELD, MASS.

WHAT ARE THE LIMITS OF HIGH POTENTIAL TRANSMISSION?

IN another column we describe the tests which have recently been made to demonstrate the possibility of transmitting electrical energy between Lauffen and Frankfort, in which potentials of over 30,000 volts were employed. These experiments appeared to indicate the practical success of the system, but in a letter appearing in the *Elektrotechnische Zeitschrift*, August Schneller, of The Hague, Holland, draws attention to certain points, which, he claims, have not been fully considered. He writes as follows:

"In our technical papers, the power transmission project from Lauffen to Frankfort, on the occasion of the Frankfort Exhibition, has been the frequent object of discussion of late. Although in the carrying out of my experiments in the preparation of ozone, I have already had considerable experience with alternating currents up to 24,000 volts potential, I have up to now avoided taking part in this discussion. Since, however, this project has been seriously taken up and spoken of by his Excellency, Dr. Von Stephan, I have regarded it as my duty to testify to the enormous difficulties of transmitting power with 20,000 volts alternating current, which make its carrying out in practice impossible. The transmitted 300 h. p. may have at the primary transformer 30,000 volts and 6.2 amperes=186,000 watts. To obtain 30,000 volts by transformation in commercially practicable apparatus, so as to be safe, is indeed difficult, but under certain construction not impossible.

"The chief difficulty in the transmission of 30,000 volts lies not, however, in the fourfold transformation and the loss thereby entailed, nor in the transformers themselves, but in the outside conductors. With 6.2 amperes, with a copper wire of 5 mm. diameter, and with 350 kilometres of wire the drop in potential amounts to only 1,830 volts = 6.1 per cent.; but the other losses which the conductors are subject to have been entirely left out of account up to the present. For the overhead conductors telegraph poles are necessary, which ought not to be more than 50 metres apart, so that altogether there will be 3,500 telegraph poles, and 7,000 oil insulators. One insulator, even an oil insulator, has an average resistance of 1,000 megohms when measured with low potential battery current. For 7,000 insulators there may then be a resistance of 150,000 ohms; then there would be, at 30,000 volts, 0.2 ampere loss, which loss of 3.2 per cent., in such an important undertaking, may almost be neglected.

"Now, however, comes the principal point: The 'charging loss,' according to my measurements, for an air dry insulator at 15,000 volts, amount to 2.3 watts; at 20,000 volts to 4.7 watts, and at 30,000 volts might reach about 15 watts. In the 7,000 insulators then, in dry weather, there would be about 100,000 watts loss. The losses in foggy or rainy weather are still left quite out of the calculation. If we assume a distance between the parallel conductors of one metre, there results, at 30,000 volts potential, a loss of 0.15 watt per metre by silent discharge; hence, for 175 kilometres, a loss of 26,000 watts. Allowing an efficiency of 95 per cent. for the primary and secondary machines and 98 per cent. for the transformers at full load, the loss in the line 6.1 per cent., the insulation loss 3.2 per cent., the 'charging loss' on the insulators at 100,000 watts, and the silent discharge in 175 kilometres of parallel conductors at 26,000 watts, then we come to the conclusion that in dry weather, from the Lauffen plant of 300 h. p. we will get in Frankfort about 37 h. p.

"There must be taken into account still further, about 6,000 square metres of condensing surface of the conductors and insulators. I have measured the sparking distance with 20,000 volts alternating current at 100 reversals per second, without any condenser, and found it to be 46 mm.; and when a condenser of 15 sq. mm. surface was included, the sparking distance was more than 80 mm.; but how great the sparking distance is with 6,000 square metres of condensing surface, goes beyond my experience. On the basis of these truths it is easily seen that the whole project is a technical impossibility."

Reports of Companies.

ANNUAL MEETING OF THE AMERICAN BELL TELEPHONE CO.

The annual meeting of the American Bell Telephone Co. was held in Boston, on March 31. Mr. J. E. Hudson, the president, read the annual report, which stated the increase in the number of stations during the year as 17,928. The estimated number of exchange connections daily in the United States is 1,438,294, a total per year of 450,000,000. The average cost to the subscriber varied, according to the size of the exchange and character of the service, from less than 2 to 14 cents per connection.

There was an increase of 28,147 underground wires during 1890, and and an increase of 38,929 instruments under rental, the total number being 483,790.

The miles of wire at the 1st of January, 1891, 240,412, against 193,213 on the 1st of January, 1890, shows an increase in that direction of 47,199 miles. Of this, something over one-half, 27,578, is a gain in mileage of wire underground—a gain that exceeds the total mileage of underground wire existing at the beginning of the year. This marks the rapid development and occupation of the underground systems, largely in New York, Chicago and Boston.

The New England Company's new switch-board has been set up. The switch-board will be in operation about the first of May, and the direct connections from the new office to subscribers' stations, through the extensive underground system of conduits and cables radiating from the Telephone building, will be completed within three or four months thereafter. With its enlarged capacity and improved equipments, the exchange will thus be in a condition to meet the requirements of its rapidly growing business.

The report was accepted and placed on file.

The treasurer's report was as follows :

DEBTORS.

Telephones	$919,274.94
Real estate	744,333.00
Stocks	32,740,580.03
Merchandise and machinery	9,932.94

Surplus account, Dec. 31, 1890		$2,151,011.61

The election of a board of directors for the ensuing year then took place, and resulted as follows :—Thomas B. Bailey, Francis Blake, Charles P. Bowditch, George L. Bradley, Alexander Cochrane, William H. Forbes, Henry S. Howe, Charles Eustis Hubbard, Gardiner G. Hubbard, John E. Hudson, Charles E. Perkins, Thomas Sanders.

The board of last year was re-elected, with the exception of the substitution of the name of Thomas B. Bailey for that of Stanton Blake, who is ill.

ANNUAL MEETING OF THE BURTON ELECTRIC COMPANY.

The annual meeting of the stockholders of the Burton Electric Company was held in Richmond, Va., on the 25th of March, when W. R. Mason, of the Electric Merchandise Company, of Chicago, was elected president ; W. J. Johnson, president Citizens' Bank, Richmond, vice-president ; C. E. Wings, treasurer ; A. Pizzini, secretary, and W. Leigh Burton, superintendent.

Reports of officers show the company to be in a prosperous condition. President Mason is looked upon as a most valuable acquisition to the Burton Company.

ELECTIONS.

Bristol, Pa.—At the annual meeting of the Bristol Electric Light and Power Company, a dividend of five per cent. on the capital stock was declared and the following directors were chosen: George A. Shoemaker, A. Weir Gilkeson, Frank F. Bell, Leopold Landreth and W. H. H. White. President, George A. Shoemaker ; secretary, A. Weir Gilkeson ; treasurer, Charles E. Scott.

Goshen, Ind.—At a meeting of the stockholders of the Citizens' Electric Company the following directors were elected : O. M. Curtis, A. E. Brownell, Albert Yates, Harris Dembufsky and M. E. Meader. The new board will organize and assume management of the plant on the first Tuesday in April.

Ware, Mass.—The Ware Electric Company has elected these officers : President, Frank M. Sibley ; vice-president, Andrew Bryson ; secretary, William C. Eaton.

STOCKS AND BONDS.

Belleville, Ill.—Judge Benjamin Boneau has appointed Mr. M. W. Weir, to be assignee of the Electric Date and Stamp Company, of East St. Louis, vice George B. Dodge, deceased.

New Bedford, Mass.—At a recent meeting of the stockholders of the Union Street Railroad Company, it was unanimously voted to authorize the directors to petition for leave to increase the capital stock of the corporation from $260,000 to $500,000. It is understood that the increased stock will be largely used in the equipment of the road with electric apparatus, and that the Fairhaven division will be the first to have the system applied.

Lancaster, N. H.—At a recent meeting of the Lancaster Electric Company, it was voted to increase the capital stock to $18,000.

DIVIDENDS.

Boston, Mass.—The New England Telegraph and Telephone Co. has declared a dividend of 75 cents a share.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

Legal Notes.

THE STATUS AND CLAIMS OF THE ADAMS ELECTRIC COMPANY.

In a recent issue we made note of the fact that the Adams Electric Co., of St. Louis, proposed to institute suit for infringement against the various companies now building electric railway apparatus. In view of these contemplated proceedings, a brief account of the facts upon which the claims for infringement are based will prove of great interest to our readers.

In a "statement," just issued by Prof. Francis E. Nipher, president of the company, we learn that the Adams Electric Railway Company, has for the basis of its organization, two patents granted to Wellington Adams, June 24, 1884. Some time prior to 1878, the patentee, Dr. Wellington Adams, while practicing medicine in Washington, D. C., conceived the idea of propelling cars by power electrically transmitted to them while in motion. His studies and experiments assumed a somewhat practical shape in the winter of 1878, when, in a course of lectures delivered in Colorado Springs, he exhibited a working model representing an electric railway system embodying this idea Being soon called to a chair in the Medical College at Denver, he there continued to pursue his investigations in this line until finally he became so much impressed with the importance and value of his invention, that he gave up his professorship and came East in order to find better facilities for developing his ideas. In 1881 he made application for a patent embodying this broad idea of propelling cars by electricity, generated at a stationary point and transmitted to them while in motion. This was, however, refused him, on the ground that the fundamental conception of the system had already been proposed and provisionally patented in England, by one, Henry Pinkus, although no publicity had been given to the matter, since the details involved in the Pinkus system were absolutely impracticable. Dr. Adams then began work on the practical details, with a view of solving the mechanical and electrical problems involved, and thus discovering and supplying the best and simplest mechanism and the most effective electrical motor. Making his headquarters at Chicago, he there devoted his entire time, as well as that of several assistants and engineers, to the carrying out of his plan, when the failure of his funds caused him to suspend operations and return to the practice of his profession, devoting only his spare time and means to the study of the great problem.

In the early part of 1883 he was invited to go to St. Louis to explain his plans to a few capitalists, who became interested in the matter and organized a company to enable him to make practical experiments on the most desirable motors and the best means of applying their power. This latter feature was the great problem which he set himself to solve. He everywhere, and always by word of mouth and by pen, contended that the solution of this one problem of the proper method of mechanically transmitting the power of the motor to the driven car, would prove the *sine qua non* of success—the key to the situation. His ideas as to the proper solution of this particular problem were embodied in two U. S. patents, numbered respectively 300,827 and 300,828, which were granted him on June 24, 1884.

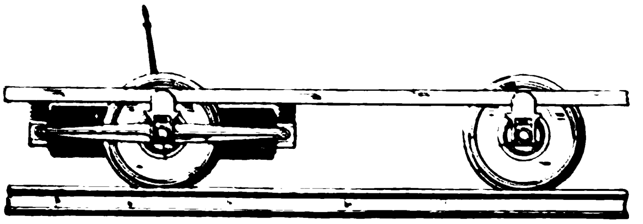

FIG. 1 OF THE ADAMS PATENT]

The accompanying engravings are reproduced from Figs. 1 and 3 of the latter patent, the claims of which are as follows:

1. The combination, with the axle which carries the driven wheels, the axle boxes or bearings, and a frame secured to or formed in one with said boxes or bearings, of an electric motor whose armature is mounted to revolve on said axle, and whose field is attached to and carried by said frame, substantially as and for the purposes hereinbefore set forth.

2. The combination with the driven wheels, their axle and axle boxes or bearings, and a field supporting frame secured to or formed in one with said boxes or bearings, of an electric motor whose armature and field are carried by said axle and frame, respectively, and intermediate power-transmitting gearing, also carried by said frame, and meshing on the one hand with a gear on the driven wheels and on the other with a gear on the armature hub.

3. The driven wheels, their axle and axle boxes or bearings and the supporting-frame secured to or formed in one with said boxes or bearings, in combination with the armature mounted to revolve on said axle, and the field-magnets, commutator-brushes, and intermediate power-transmitting gearing mounted in and carried by said supporting-frame, under the arrangement and for operation as hereinbefore set forth.

Soon after the patents were granted, efforts were made to secure contracts for the equipment of various street railroads. But the street railroad companies could not then be convinced of the practicability of the project. The inventor then concluded that the only way out of the difficulty would be to construct a road of his own, the primary object of which should be to utilize his own inventions and thus prove their practical value. This proposed road, embodying his inventions, was exhibited at the first St. Louis Exposition, in 1884, and the following year he succeeded in securing from the Municipal Assembly a franchise for an elevated electric railway, thus standing on the threshold of success as the builder of the first extensive electric railroad system in the world. But he was doomed to disappointment, for the mayor of St. Louis vetoed the Adams Elevated Electric Railway bill. This reverse brought panic and discouragement to the gentlemen composing the company, who felt that they had spent enough money on electric railways, and in efforts to demonstrate the practical value of their patents. An elaborate and very interesting paper embodying his ideas, was printed by Dr. Adams in the *Journal of the Association of Engineering Societies* in 1884, and was republished by him in pamphlet form in 1886. It was read before the Engineers' Club, of St. Louis, April 23, 1884.

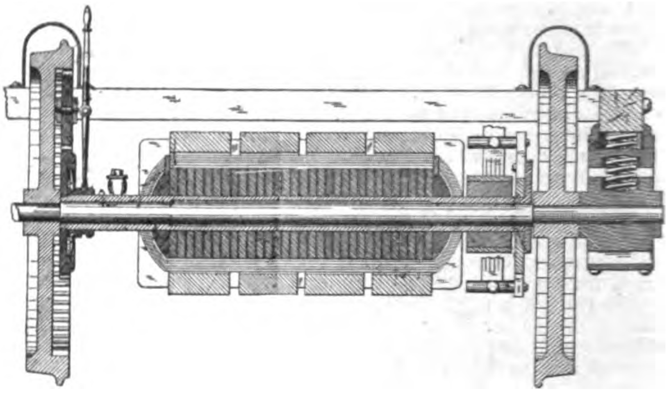

FIG. 3 OF THE ADAMS PATENT.

The company claims that all railway cars now operating electrically embody the features of the Adams patents in the machinery which propels them, and it is these features which has made the present success possible. Furthermore, that the improvements that are now being made and which are promised in the future, simply consist in copying more faithfully the specific device in which Dr. Adams embodied his invention.

The officers of the company are: Francis E. Nipher, president; Ewing Hill, secretary and treasurer, and Wellington Adams, general manager.

IMPORTANT ELECTRICAL UTILIZATION OF WATER-POWER AT JOPLIN, MO.

Note has been made from time to time of the important work that has lately been undertaken near Joplin, by the Southwestern Electric Light and Water Power Co. We are now in receipt of an interesting letter on this subject from Mr. Charles E. Hart, superintendent of the company, who says:—"Our plant consists of a very fine natural water power about five and a half miles from this city, which, when we complete our present installation will be some 2,000 effective horse power. We have a very fine concrete dam and our turbines are James Leffel & Co. 66 inch wheels, which we work under a head of 21 feet. We transmit our power into our generating station by a large leather belt 65 feet between driving centres. All the pulleys on our main shaft are fitted with Eclipse friction clutches, thus giving us good control of all our apparatus. Our electrical equipment consists of one 1,500 light 2,000 volt alternating dynamo, and two 50 light 2,000 c. p. arc machines. We are using the light from these machines at Joplin, from five and a half to six miles away from the station.

"Our power transmission will extend for from two and a half to four miles, and for this coming summer will consist of about 300 h. p., which will be divided into units of from 5 to 30 h. p. motors, which we shall put out at an average rental of three cents per horse-power hour. We have a very fine pole line of 35 foot poles, with eight inch tops, set six feet deep, and the entire line is painted and well guyed. We are engaged in working out a problem here. While great advance has been made upon it already, we still know of no place that is transmitting as large an amount of horse-power as long a distance as we will be doing in the near future. I might state that all our electrical equipment is Thomson-Houston make."

MR. BERT POWELL has obtained the important position of superintendent of the Electric Light and Power Co., of Eau Claire, Wis.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MARCH 31, 1891.

Alarms and Signals :—

Electric Alarm for Shaft Bearing, G. Hanna, 449,411. Filed Dec. 24, 1890.
Electro-magnetic apparatus adapted to notify of any derangement or wearing in the out-board bracket supporting the shafts of twin-screw steamships.

Repeater, F. W. Cole, 449,574. Filed May 12, 1890.
A repeater for alarm or signal circuits, as in police service, for the automatic transmission over any number of circuits of signals received at a central station over one circuit.

Non-Interference Signal Box, F. W. Cole, 449,575. Filed June 9, 1890.
Relates to the locking and actuating mechanism of boxes employing a signaling train.

Non-Interference Signal Box, F. W. Cole, 449,576. Filed Oct. 20, 1890.
Relates to the construction and operation of locking, and releasing mechanism.

Conductors, Conduits and Insulators :—

Art of Covering Electric Wires, T. W. Norman, 449,163. Filed April 29, 1890.
Relates to a method of covering insulated wires or cables with lead or other metal. The metal is applied in the form of a flat strip, or ribbon, having scarfed edges to secure a smooth overlap ; the edges are then soldered and the covering compressed.

Insulated Electric Conductor, J. D. Bishop, 449,400. Filed Sept. 22, 1890.
The conducting core is wound with a paper ribbon the spiral edges of which are separated by a spiral air space and enclosed within a protective sheath.

Distribution :—

Regulating Apparatus for Electric Currents, W. Lahmeyer, 449,288. Filed Feb. 9, 1888.
For regulating automatically from a central station, without any special circuit, the current received by lamps connected at the ends of a lighting circuit. Consists of a cistern of mercury, floats, and multiple contacts, with a series of relays arranged on high resistance shunts, successively thrown into action by varying strength of current in the main lead.

Dynamos and Motors :—

Dynamo Regulator, B. H. Fisher, 419,245. Filed Sept. 15, 1890.
The motion for adjusting the brushes is derived from that of one of the field-magnets. An additional field-magnet is provided and is so mounted as to be capable of movement under changes in the "neutral line" and of communicating motion to the brushes.

Electric Contact, O. J. Depp, 449,348. Filed Jan. 24, 1891.
Adapted for commutator brushes and arranged to prevent the flow of current through the pressure springs.

Galvanic and Thermo-Electric Batteries :

Thermo-Electric Batteries, J. N. Webb, 449,186. Filed July 19, 1890.
A portable battery. The end parts, for heating or cooling, are of large size relatively to the connecting strips, which latter may be flexible.

Galvanic Battery, H. P. Stoecker, 449,299. Filed Dec. 4, 1890.
Relates to the method of attaching connecting wires, and to a cathode formed of a series of carbon rods arranged in contact with each other.

Lamps and Appurtenances :—

Hanger for Electric Lamps, H. A. Foster, 449,153. Filed August 1, 1890.
For suspending arc lamps from the side walls of buildings or other similar positions.

Electric Arc Lamp, J. H. R. Ward, 449,236. Filed Dec. 8, 1890.
Relates to the globe-holder and is designed to facilitate the removal and replacing of the globe.

Electric Arc Lamp, J. H. R. Ward, 449,237. Filed Dec. 8, 1890.
Relates to the mechanical details of arc lamps of the type adapted for low electromotive force.

Electric Arc Lamp, J. H. R. Ward, 449.238. Filed Dec. 11, 1890.
Relates particularly to means for improving the uniformity of the arc, especially during the period immediately following the turning on of the circuit.

Hanger Board for Electric Fixtures, G. R. Lean, 449,266. Filed June 9, 1890.
Especially adapted for use where lamp fixtures must be made very short.

Incandescent Electric Lamp Socket, F. A. Weller, 449,604. Filed Aug. 11, 1890.
Intended to facilitate connecting, disconnecting or adjusting the circuit wires.

Medical and Surgical :—

Electric Belt, D. P. Andrus, 449,345. Filed Nov. 7, 1890.

Electro-Therapeutic Syringe, E. Bartsch, 449,651. Filed June 28, 1890.

Metallurgical :—

Magnetic Separator, R. R. Moffatt, 449,610. Filed Aug. 25, 1890.
Has two rotating drums with an electro-magnet or magnets located outside of the drums and having a stationary pole-piece within each drum ; the pole-piece is magnetically connected with the magnet core through the axis of the drums.

Metal Working :

Method of and Apparatus for Electric Soldering, A. Robinson, 449,258. Filed Apr. 18, 1890.

Consists in passing a current through the solder to be applied, between two metallic conductors, which conductors with their adhering solder are applied to the metal of the joint, thus heating the metal by the combined effect of the melted solder and of some portion of the electric current.

Manufacturing Chains by Electric Welding Processes, E. Thomson, 449,356. Filed Apr. 28, 1890.
The abutting ends of chain links are welded by electric current : the electric heat is applied not only at the joint but also at the continuous part of the link opposite the joint ; the link is then subjected to pressure in a line transverse to that connecting the joint and the opposite heated portion. This method may be applied to produce chains having a protuberance or enlargement on the side of the links.

Burr Preventer for Electric Welding Machines, E. Thomson, 449,857. Filed Aug. 15, 1890.
The upset or enlarged portions usually produced adjacent to the ends or edges of the pieces of metal when joined are avoided by the employment of compressing rockers, or segments, pivoted so as to swing across the joint during the operation of welding.

Miscellaneous :—

Electric Switch, W. White, 449,188. Filed Dec. 3, 1889.
Intended to make a very rapid and complete break of contact.

Electro-Magnetic Device, M. G. Crane, 449,206. Filed July 16, 1888.
Shown as applied to an electric gong. The mechanical features are intended to provide for the development of a more than usually powerful blow from the hammer.

Electric Fuse, G. F. Curtiss, 449,209. Filed June 20, 1890.
The fuse wire is provided with an enclosing tube having a bore of such diameter that the wire fills the tube with very slight clearance, for the purpose of causing the sudden expulsion of the wire when melted.

Electric Switch, H. T. Clark, 449,282. Filed Feb. 25, 1891.
A compression and sliding contact.

Fuse for Electric Circuits, F. W. Maxstadt, 449.280. Filed Jan. 10, 1891.
Details of construction relating chiefly to the holder.

Cut-Out, C. S. Van Nuis, 449,301. Filed Aug. 18, 1890.
A "snap" switch designed especially for heavy currents and for compactness.

Electric Contact Protector, R. Varley, Jr., 499,202. Filed Nov. 28, 1890.
For the protection of contact points in electrical apparatus. It consists of two discs of flexible material connected together around their edges and having central openings for the electrodes,

Binding Post for Electric Wires, H. P. Ball, 419,307. Filed Dec. 16, 1890.
Adapted for wires of different sizes ; holds the wire by wedge action.

Electro-Magnet, F. A. Wessel, 449,358. Filed Nov. 19, 1890.
Relates to a method of winding electro-magnets and to permit the easy division of the wire into sections, each consisting of a single layer of wire. Applicable to field-magnets of dynamos.

Electric Switch-Box, J. H. Dean, 449,362. Filed Nov. 4, 1890.
A rheostatic-switch for use in connection with electric motors.

Electric Heating Apparatus, M. W. Dewey, 449,404. Filed Apr. 28, 1890.
For heating apartments by Electricity. It is a combination of an exposed electric heater and a ventilating fan mounted upon the same support or frame, the fan serving to distribute the heat.

System of Operating Electric Elevators, W. Baxter, Jr., 449,611. Filed Mar. 17, 1888.
A system of operating elevators by electric motors worked out with great elaboration and comprising devices and apparatus for securing control of the motive power and preventing mishaps under a variety of circumstances.

Railways and Appliances :—

Electric Railway Conduit, F. O. Blackwell, 449,196. Filed Mar. 5, 1889.
Consists of devices for supporting the insulated supply conductor. A common fastening device secures a clamp to a support in the upper part of the conduit and at the same time secures the conductor to the clamp.

Electric Motor Truck, F. O. Blackwell, 449,197. Filed Aug. 31, 1889.
The motor has two bearings upon the driven axle, to which it is geared, and has a single bearing upon the opposite axle supporting the free end of the motor.

Guard for Electric Railway Trolleys, A. W. Mitchell, 449,226. Filed June 23, 1890.
Has two arms, each having a flange extending over the wheel and provided with a slit or opening in line with and for the rim or edge of the wheel to project through.

Electrical Railway System, S. F. B. Morse, 449,227. Filed Oct. 29, 1890.
Combines an overhead trolley conductor and an insulated or underground conductor, both divided into corresponding and independent sections, switch levers or other devices at the junctions of the sections for connecting a conductor of one section with a conductor of another ; so that a section of one circuit may be substituted for its corresponding section in the other ; the switch levers are operated by electro-magnets ; supplemental circuits co-extensive with and corresponding to the sections on the main conductor are provided and include the electro-magnetic switching devices ; the supplemental circuit is adapted to be controlled by the movement of the cars.

Electric Lighting System, G. Gibbs, 419,474. Filed Aug. 14, 1890.
Relates particularly to the lighting of railway trains and to the direct supply of current by a dynamo. Includes the provision of a storage battery and an automatic switch mechanism by which the battery is held normally in circuit with leads ; an auxiliary circuit containing lamps and connected with the storage battery. On the cessation of current through the main circuit the auxiliary circuit is completed through the storage battery.

Guard for Electric Railway Trolleys, A. W. Mitchell, 449,490. Filed Dec. 1, 1890.
Has two arms, a cross-bar connecting the arms together, each arm having a curved slot and a flange extending over the trolley wheels, each arm at its side has a pin engaging with the curved slot, and a slot engaging with the journal pin of the trolley wheel ; a lever pivoted to the trolley rod engages with the cross bar of the flange and arms.

Automatic Trolley Catcher for Electric Railways, B. J. Parsons, 449,569. Filed Aug. 27, 1890.
To catch the trolley when it slips from the conductor and to draw it down to a suitable distance. Consists of a spring actuated winding cylinder or drum and holding or releasing mechanism.

Electric Railway Signal, S. Tompkins, 419,689. Filed Dec. 9, 1889.
For signals to and from moving trains generally, and particularly to the case of signaling to engineers upon their engines the proximity of other engines upon the same track. Employs a series of aligned conductor sections similarly connected ; the arrangement is such that each section exists between sections belonging to a group or groups other than its own ; groups in one series are connected with respective groups of the other series.

Telegraphs :—

Telegraph-Transmitter, H. G. Robbins, 449,174. Filed Nov. 29, 1890.
A key-board transmitter for Morse signals.

Telephones and Apparatus :—

Telephone Sound Transmitter, A. D. Schatz, 449,180. Filed Mar. 1, 1888.
A horn shaped sound conveyor for attachment to transmitting telephones, provided with an opening in its convex side near the large end. The speaker uses the opening in the side of the horn.

Telephone, W. Humans, 419,254. Filed July 23. 1885.
A magneto telephone. Consists of a permanent magnet whose elements are connected pole to pole to form a case, a diaphragm extending across the open end of the magnetic case thus formed, one or more pole pieces and coils within the magnetic case.

Patent Notes.

THE SLATTERY-STANLEY INTERFERENCE.—PARALLEL DISTRIBUTION BY ALTERNATING CURRENTS—COMMISSIONER'S DECISION FOR STANLEY.

The decision of the commissioner of patents in the interference case of Stanley v. Slattery, made February 24 and noticed in THE ELECTRICAL ENGINEER of March 4, is printed in the *Patent Office Gazette* of March 24. The case was on appeal from the Examiners-in-Chief who had awarded priority to Stanley. Stanley's application was filed August 15, 1888, at which time Slattery's patent had been issued, dated July 31, 1888. The commissioner, after an analysis of the case, confirmed the decision of the Examiners-in-Chief.

In view of the relative dates of Slattery's patent and Stanley's application the burden of proof was upon Stanley. In determining whether he had discharged that burden the commissioner first inquired into the proper construction of the points at issue. He found the limitation, qualification, or feature relied upon to impart novelty, in the following language from the first issue:

> Each converter made with a primary coil containing such length of wire exposed to magneto-electric induction that when operated by the dynamo with which it is to be used, with its secondary circuit open the electrical pressure and counter-pressure in its primary circuit shall be equal.

Similar language of limitation was found in each of the five issues in controversy, all of which were combinations, and in the 5th issue it was required that each converter shall contain

> A soft iron core weighing two pounds for each ampere of current normally produced in its secondary circuit.

The commissioner disregarded other and minor features of difference in the several issues.

"It is clear," he said, "that the feature or limitation of having the counter electromotive force or counter pressure produced in the primary coil of the converter equal to the applied electromotive force when the secondary circuit is open is essential to the issues, and it is equally clear that the primary coil of the converter must contain such length of wire exposed to electro magnetic induction as will bring about this equality of pressure and counter-pressure. I do not understand, however, that this equality of pressure and counter-pressure need be equal in an absolute sense."

Slattery's specification says:

> In this condition the ammeter will show no current whatever in the circuit of the primary when the secondary circuit is open.

Stanley, however, only requires proximate equality, and says:

> When so constructed an ammeter will practically show no current when the secondary circuit is open.

The commissioner, therefore, conceived the several issues to be satisfied by the substantial equality of applied and counter electromotive force when the secondary circuit is open.

Stanley's principal evidence related to a plant erected at Great Barrington, Mass., in March, 1886, in which he had seven converters arranged in multiple arc and supplying over 100 lamps, and having a capacity of 200 16 candle-power lamps. This plant was first started on March 16, 1886, and continued in successful operation until June 17 of the same year. It embodied the issues of this interference.

Stanley had produced as an exhibit in the case an old specification, dated November 26, 1885, which was never filed in the Patent Office, and which in its suggested claim distinctly called for

> A counter E. M. F. opposing the E. M. F. applied to their primary circuit of sufficient value to practically obstruct the flow of current between the mains when their secondary circuits are open.

And it also exhibited a rough drawing corresponding with the drawing of the application in interference. This paper, the commissioner said, made it difficult to avoid the inference that Stanley contemplated making the counter electromotive force practically equal to the applied electromotive force when the secondary circuit should be open, and that he also perceived and recognized the relation to the accomplishment of that result of the number of turns and lengths of wire in the primary coil. A paragraph of the claim of this old specification also set forth the fact that the core of the converter must be of magnetic resistance low enough to allow an equal or proportionate magnetic absorption throughout its working limits. Stanley had testified that the invention described in this unfiled specification, Exhibit 1, was embodied in an apparatus worked and tested at Pittsburgh, in September, 1885, and that the apparatus designed and used in Pittsburgh was a complete embodiment of the invention described and claimed in his application in interference; and that he considered at the time he had made an invention of value and importance. The proofs had shown that the Great Barrington plant was set up in March, 1886. It was distinctly stated that the electrical pressure and counter pressure in the primary circuit of the converter used at Great Barrington were approximately equal, so nearly so that the counter pressure approached in value the applied pressure within one two-hundredth part of its value. All the Great Barrington converters were provided with primary coils within the present issues.

Concluding his opinion, the commissioners says:

"Inasmuch as Slattery did not conceive the invention prior to June, 1886, nor reduce it to practice before December of the same year, it follows that the decision of the Examiners-in-Chief adjudicating priority to Stanley must be affirmed."

Appointments, Etc.

MR. W. B. FERGUSON, late with the Thomson-Houston Electric Company, is now New England manager of the Detroit Electrical Works, the builders of the Rae system.

MR. WALTER N. SPERRY, at present manager of the Waterbury division of the New England Telephone Company, will in addition become manager of the Birmingham division. Mr. Sperry will spend part of his time between both stations. He will, however, have an assistant residing permanently in Birmingham, in the person of R. H. Gray, at present connected with the system in Waterbury.

MR. H. F. PARSHALL, late general manager and electrician of the Wenstrom Consolidated Dynamo and Motor Co., of Baltimore, Md., has found it necessary on account of the ill health of Mrs. Parshall to resign his position with that company. He has now gone South, where he hopes the change of climate may restore to Mrs. Parshall her former health. Mr. L. Atwood, formerly of Chadbourne, Hazelton & Co., of Philadelphia, Pa., succeeds Mr. Parshall as general manager.

MR. W. H. PALMER, formerly of the Thomson-Houston Co., and late superintendent of the Railway Department of the Wenstrom Co., has been appointed electrician of the Wenstrom Consolidated Dynamo and Motor Co., with supervision of the manufacturing and construction. Mr. E. C. Sickles, M. E., who has been for some time with the company is his assistant.

Obituary.

ALBON P. MAN.

The death occurred last week, of Albon P. Man, a leading lawyer of this city and one of the founders of the Sawyer-Man Company. Mr. Man was associated with the late W. E. Sawyer many years ago, in the effort to produce a commercial incandescent lamp, and their work is fully recorded in the evidence brought out by the extensive patent litigations on this subject. He took an active interest in the affairs of the Sawyer-Man Co., for some time after its organization, but of late had been occupied with a variety of other important enterprises.

MILEAGE MADE BY ELECTRIC CARS IN DENVER.

Subjoined is the record made by two electric cars of the Thomson-Houston system operated by the Denver Tramway Co.:

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

If you want to hear how bad trade is, hunt up a man who doesn't advertise.

THE "A. B. C." TRADE CATALOGUE.

THE improvement in electrical trade catalogues is very noticeable this year, more and more money being spent on them and more and more care being given to their contents. We have already had occasion to speak of creditable productions in this line of the present season, and now have before us an extremely artistic and useful publication in the April catalogue of Alexander, Barney & Chapin. Herewith is shown a reduced fac simile of the design on the front cover. The catalogue is in quarto form, 7 x 10 inches, and is beautifully printed. The back cover folds over the front cover in pocket book style, and attached to it at the lower corner is an embossed fac simile of a switch cover and handle, making not only a very striking innovation but serving the useful purpose of a book marker. The catalogue runs nearly 250 pages, and all the apparatus shown is carefully numbered, priced and illustrated. A most commendable feature, moreover, is that of giving very full and explicit descriptions of the leading instruments and devices. This has always been wanting in catalogues of a comprehensive and trade character, and the new departure shows excellent judgment as well as a keen appreciation of the fact that purchasers very often wish to be fully informed as to the special merits and characteristics of the apparatus they are buying. We note that the same idea of giving essential details has been carried out in other lines of supplies contained in the catalogue, rendering it very valuable for reference. The catalogue embodies, further, a number of useful tables of sizes, etc., of different supplies, and is completely indexed. The young house is to be warmly congratulated on its enterprise and success in this effort, which redounds so much to its credit as a representative and progressive supply concern.

A LARGE RAE ELECTRIC RAILWAY CONTRACT.

On March 30, the Common Council of Grand Rapids, Mich., granted the petition of the Valley City Street and Cable Railway Co., whereupon Mr. Chas. A. Benton, the energetic general agent of the Detroit Electrical Works, closed a contract, promptly, with the Company for ten 30 h. p. Rae equipments, mounted on McGuire Mfg. Co.'s steel trucks, the road to be in operation by May 15. This is only a preliminary order, as the total number of equipments required is about 40. The company will eventually utilize the Hamilton Corliss engines, now furnishing power for the cable system, and it is understood that the cable system is not of long continuance. The Detroit Electrical Works have now running just upon 200 street car equipments, a really phenomenal record, in view of the shortness of the time they have been building the Rae apparatus. Mr. Benton is the prouder of the order, from the fact that it was secured in hot competition, and despite strenuous advocacy of the single reduction and "gearless" motors.

MILLIKEN METALLIC POLES.

Messrs Milliken Bros., of New York and Chicago, have issued a pamphlet descriptive of their metallic poles for electric lighting and street railway work. The publication is extremely artistic in its finish, and is handsomely illustrated from photographs. It also contains some useful information for engineers and all others interested in electric lighting plants, in regard to the best methods of construction.

PARTRICK & CARTER CO.

THE above company, of 125 South Second street, Philadelphia, have just issued a large, handsome and complete catalogue and price list of their electrical supplies and goods. They have aimed to make this the best and most complete of the many issued by the house up to date, and flatter themselves, with reason, that they have succeeded. In its pages will be found pretty much everything that can be called for by the user or buyer of things electrical. It also has the merit of careful and well considered arrangement. It will be mailed free with trade discounts on receipt of request for it, accompanied by business card or other evidence that the applicant is a dealer.

The firm have also prepared a very effective and taking "Sample" show board, containing their leading specialties, all connected up in complete working order for practical exhibition, with the customer's name in gilt letters on glass. It is of hard wood, light or dark, as required, and is 15 by 22 inches. The price complete with battery, f. o. b., is only $20. The goods are prettily grouped and the board will make an attractive ornament for any store.

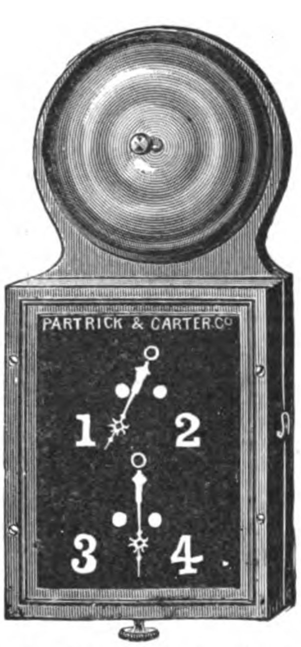

FIG. 1.—THE "INDICATOR" BELL.

In the accompanying illustrations, Fig. 1 shows a modification of the celebrated indicator bell manufactured by this company. It is perfect in all its working parts, and in every way reliable. Fig. 2 shows a view of the "King" bell, which is so made that only the gong is exposed. It is extremely compact, and is so arranged that the hammer is locked and the bell cannot ring, no matter how much shaken, until the circuit is closed. This bell is especially adapted for carriage and railway use.

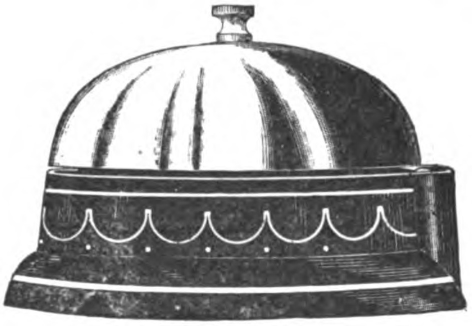

FIG. 2.—THE "KING" BELL.

C. R. VINCENT & CO.

C. R. Vincent & Co., 15 Cortlandt street, New York, have secured contract for complete installation for a 500 h. p. steam plant for the West End street railroad, Lancaster, Pa.

THE PAGE BELTING CO.

The Page Belting Co., of Concord, N. H., with stores at New York, Boston, Chicago and San Francisco, report a very large trade, and largely increased business over one year ago.

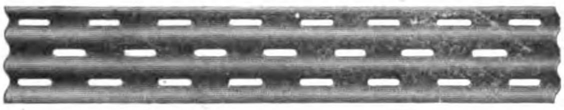
Their patent Acme Link belts are receiving a very large sale, not only for electric purposes, but also, among other things, for driving fans in large iron manufacturing establishments.

Two of these belts, 12 in. wide, have been running in one establishment in Pennsylvania one year, day and night, for this purpose, at a speed of 5,761 feet per minute, thus demonstrating their adaptability for high speed work. Among the orders which they have recently filled is one for some very large belts sent to Omaha, Neb. They have published their catalogue for 1891, which should be in the hands of dealers and users of belting. It contains a full list of all the goods they manufacture. It has a very comprehensive cipher code for use in ordering goods. There is in it an article of great practical value, entitled, "Practical Rules for the Purchase and Use of Belting." The catalogue sets forth in a very clear and explicit manner the kinds and grades of belting which should be purchased for different kinds of work. It also has a valuable appendix, showing a great variety of ways in which belting is applied to the propelling of machinery under extraordinary circumstances.

They have also just issued a neat and useful circular giving directions for putting on endless belts, setting forth the methods in a very clear manner. Among other specialties which are manufactured by this company are "dynamo" double belts. These are double leather belts of great excellence and made with the very best of care and from the best of material. A very neat circular has just been issued by the company describing this class of goods.

CORRUGATED METALLIC LATH.

Nothing spoils the appearance of a new building so quickly as cracked walls and ceilings, and the employment of ordinary wood lath with its uneven shrinkage is the cause of most of the unsightliness of such buildings. Besides, the wood lathing introduces an added risk from fire, which it is desirable to overcome, especially in connection with electric light stations, and to that end the Cincinnati Corrugating Co., of Piqua, O., several years ago brought out a corrugated metallic lath which has from its introduction met with unqualified success.



CORRUGATED METALLIC LATH.

The accompanying engraving shows one style of lath made by this firm, in which the oval perforations are situated at the bottoms of the corrugations. More recently they have introduced a new style with round perforations, which is becoming equally popular. In this the total space for key afforded by the openings is the same as though they were oval, as they are more numerous. They are also made on the sides, instead of at the bottom of the corrugations, thus best preserving the rigidity of the lath and allowing the motor to key at an angle, which gives it a better hold.

Corrugated metal lathing can be adapted to any kind of surface, requires no stretching, and, while possessing great rigidity, can be bent to a semicircle where required for use on curved surfaces. It is economical of plaster, requires no cross furring, and can be used over 24 inch openings without danger of sagging.

This lath is usually made three corrugations wide, and in lengths ranging from 16 to 96 inches, but can be made specially in sheets up to ten feet long, and twelve inches wide. Among the valuable features claimed, is the fact that the mortar adheres firmly to the surface of the metal itself, in addition to the hold given by the perforations, and that it is the only style of lath that can be applied by one man.

NOYE ENGINES FOR THE DETROIT EDISON PLANT.

The Edison Illuminating Company of Detroit, Michigan, have contracted with Fairbanks, Morse & Co., of Chicago, Ill., for a 400 h. p. non-condensing tandem compound engine, built by the John T. Noye Manufacturing Co., of Buffalo, N. Y. This will be an exceptionally fine engine of their "B" type, suitable for heavy duty. Attached to it will be two of the new pattern Edison machines. These machines will be among the first of this size built by the Edison Company.

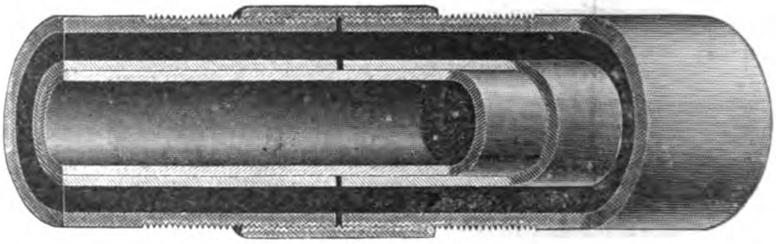
R. T. WHITE'S STREET RAILWAY TRACK SPECIALTIES.

Mr. R. T. White has lately made arrangements with Mr. W. D. Thomas, 141 Byran street, Savannah, Georgia, to act as his Southern agent; Messrs. D. E. Garrison & Co., Laclede Building, St. Louis, Mo., to act as St. Louis and Southwestern agents, and the Great Western Electric Supply Co., 190 and 192 Fifth avenue, Chicago, Ill., as his Chicago and Northwestern agents. As these are very responsible and pushing firms, he expects to be able to sell a large amount of material through them, in addition to the large orders he is now obtaining. He has some very good orders on hand from street railway companies for track material.

INTERIOR CONDUIT AND INSULATION CO.

In order to meet a demand which has arisen for a single duct conduit of cheap, durable and efficient character, the Interior Conduit and Insulation Company have adapted their well-known insulated tubing to fit telescopically into a wrought iron pipe, as shown in the accompanying illustration. The full space between the tubing and the iron is filled in with insulating compound, thus absolutely excluding all moisture and gases. These pipes are made up in 10-foot sections, and, when laid, are coupled together by suitable wrought iron couplings. These sections of 10 feet each are made up in the works, complete and ready for shipment.

In laying, these sections are converted into a continuous duct, having practically no junctions, by employing individual insulated tubes whose lengths are the same as the iron pipe sections, but whose external diameter is slightly less than the internal diameter of tube contained in the iron pipe. These individual tubes are coated at the moment of laying, with an insulating compound or cement and telescoped into the iron pipe section to the depth of just one-half their length in each section. A liberal supply of cementing compound is then placed upon each end of the sections to be joined, and the ends of the iron pipe brought together firmly by a screw coupling. Thus the insulated iron covered duct so formed, of two complete insulating tubes cemented together and held apart from the iron pipe by a lining of insulating compound, becomes, to all intents and purposes, as perfect in its continuity as if manufactured in the factory in one unbroken length.



SINGLE DUCT CONDUIT FOR HIGH TENSION CIRCUITS.

This single duct conduit, as well as the multiple duct system, of the same company, provides in the conduit itself, without special investment therefor, an insulation ample for all purposes, and they are thereby enabled to employ bare copper conductors therein in place of the insulations and metallic protections heretofore used for underground work.

This conduit will be found specially desirable for the use of arc lighting companies and others employing a series system. It will also be found specially desirable for carrying the feeders of electric street railway lines: in fact in any place where a single duct conduit of high insulation is required. By reason of its cheapness and the economy of bare copper wires, it is unnecessary to predict a large and ready market for this admirable conduit.

THE DIRECT UNITED STATES CABLE WINS THE RACE.

The Direct United States Cable Company has again had the satisfaction, it states, of distancing all competitors in the time occupied in cabling the news of the Oxford-Cambridge boat race across the Atlantic. The Direct Company has accomplished this feat so often, it says, that in order to be fair to the other cable companies, it now proposes to handicap itself by conceding them a time allowance.

CATALOGUE OF THE ELECTRICAL ENGINEERING AND SUPPLY COMPANY OF SYRACUSE.

The new catalogue of the Electric Engineering and Supply Co., of Syracuse, is one of the most complete that has come under our notice. It is neatly gotten up, profusely illustrated, and contains over 200 pages of matter descriptive of the electrical and mechanical supplies manufactured by the company, including many specialties. The catalogue also contains a complete cross reference index, which greatly increases its value.

THE STILWELL & BIERCE MANUFACTURING COMPANY.

We take pleasure in calling the attention of our readers to an admirable electric light and railway water power plant recently installed for the Olympia Light and Power Co., at Olympia, Washington, by the Stilwell & Bierce Mfg. Co., of Dayton, Ohio.

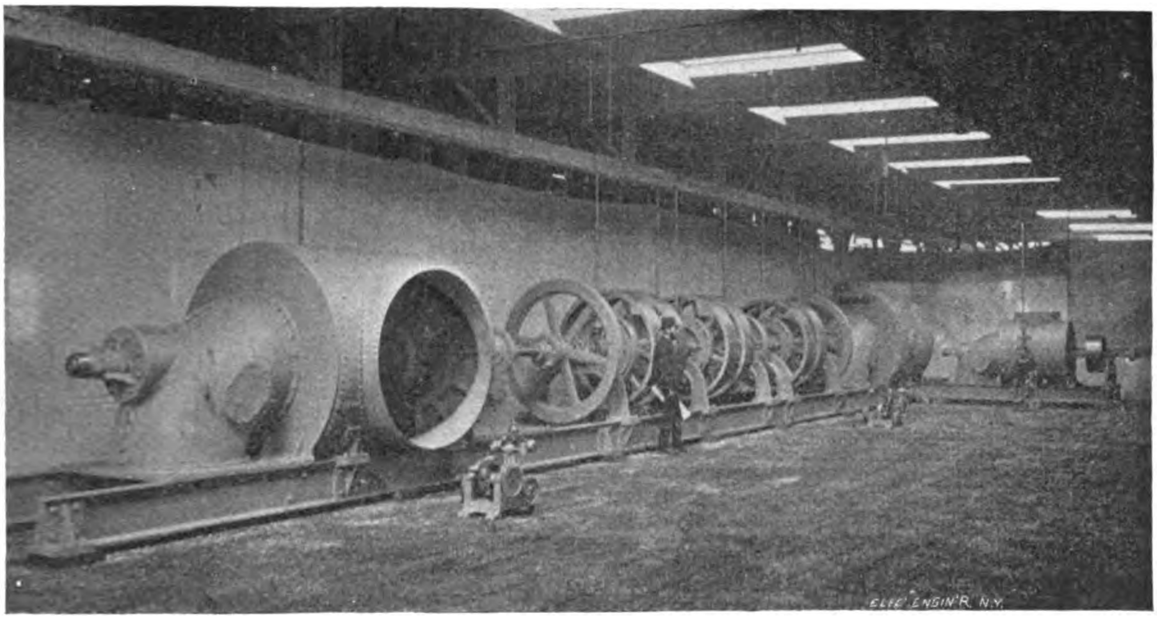
This plant, which is shown in the accompanying illustration, consists of two pairs of 25 inch wheels running on a horizontal shaft under a head of 24 feet, developing 104 h. p. per wheel, or 416 h. p. in the aggregate, and arranged as follows:

One pair of wheels is placed at each end of a line of shafting and the power is taken off by means of 6 friction pulleys on the line; the clutches for engaging them are operated by hand wheels from the dynamo floor above, and by means of a clutch coupling, placed midway between the two pairs of wheels, the line may be run in one or two sections at will.

The water wheels are encased in wrought iron flumes, and are so placed that the shaft is about 10½ feet above the water in the wheelpit, the water discharging through a draft-tube.

The water-wheel gate is operated by a hand-wheel in the dynamo room above. Each pair of wheels has a governor attached for controlling the speed, and there are also two fly wheels weighing 2,800 lbs. each on the shaft.

The features worthy of special attention in connection with this plant are the water-wheels running on a horizontal axis, doing away with all gearing, and the opportunity, by means of the clutch coupling, of supplementing power on either section in case of failure on the other, or of running all or any part of the lighting section from the railroad section, or vice versa.



STILWELL & BIERCE WATER WHEEL PLANT AT OLYMPIA WASH.

The Stilwell & Bierce Mfg. Co. make a specialty of this class of construction, and are building more horizontal wheel work than all other builders combined.

The Stilwell & Bierce Mfg. Co. are proprietors of one of the largest machinery establishments in the West. This enterprise dates back to 1866, and was commenced in a small way by G. N. Bierce and E. R. Stilwell, and this moderate start formed the nucleus from which was developed the enormous business now operated by the Stilwell & Bierce Mfg. Co., which was incorporated in 1870. Their shops occupy a frontage of nearly 1,000 feet, with large rear additions. The mechanical department embraces the heaviest and most modern machinery appliances and tools, most of which is of late introduction, the facilities of the works having recently been nearly doubled in capacity. It is operated by water power with steam power in reserve, and a force of about 350 skilled workman are here given lucrative employment. The establishment is divided into three general departments, each manned by an accomplished engineer with a suitable force of assistants. These departments cover the manufacture of the celebrated Victor Turbine Water Wheels, both vertical and horizontal, in great variety of styles and sizes and power connections of all kinds, their catalogue of gears, pulleys, etc., being very complete and extensive; modern flour mill machinery, including Odell's roller mills, reels, purifiers, etc., the good qualities of which are attested by the number of large first-class flour mills built by them; and devices for heating and purifying the feed-water for steam boilers, prominent among which are "Stilwell's exhaust heater and filter combined," of which over 5,000 are in daily use, and "Stilwell's live steam purifier," a more recent invention which is very successful in removing from feed water sulphates of lime, magnesia and other impurities. Handsome catalogues fully illustrating and describing their various specialties will be cheerfully furnished to all interested parties who will state their requirements and apply to Stilwell & Bierce Mfg. Co., Dayton, Ohio.

THE NEW CENTRAL ELECTRIC CATALOGUE.

We are in receipt of the new catalogue just issued by the Central Electric Co., of Chicago. It is a massive production of generous western proportions, 8 x 10½ inches, solidly and richly bound in colored boards, and running a length of no fewer than 300 pages. Chicago may well be proud of such a concern, the picture of whose large offices and warehouses at 116 and 118 Franklin street, is shown as a frontispiece. The catalogue is divided into sections, and it is interesting to note that the first is given up to incandescent electric light supplies, occupying nearly 80 pages. Then come arc light supplies, which are necessarily less extensive, and then come about 40 pages of "construction material" proper, followed up by 20 more of miscellaneous construction details, including belts, filters, rubber gloves, interior conduits, etc. Next comes an important section headed "tools," and the variety here shown is such as to demonstrate that the electrical business has already become one of the largest departments of the hardware industry. Following this is the section devoted to wires and cables. The Central Electric Co. are general western agents for all the Okonite specialties, and hence attention is given first to these, prefaced by some valuable data as to the nature of Okonite insulation. The Candee wires and Manson tapes are not forgotten in this category, which is succeeded by waterproof wires, magnet wires, German silver resistances, sheet copper, etc. We now come to test instruments, here set forth in admirable profusion and detail in about 25 pages. A large portion of space is then given up to electric railway supplies, household goods, electrical books, underwriters' rules and regulations, wire gauges, tables of resistances, electrical units and a telegraphic code.

A very useful detail in this catalogue is the care that has been taken to place opposite each article a "trade word," by means of which a single word stands sometimes for as many as ten in the catalogue, and avoids any confusion or any necessity for compiling a special code when beginning to order by telegraph for a new contract or installation.

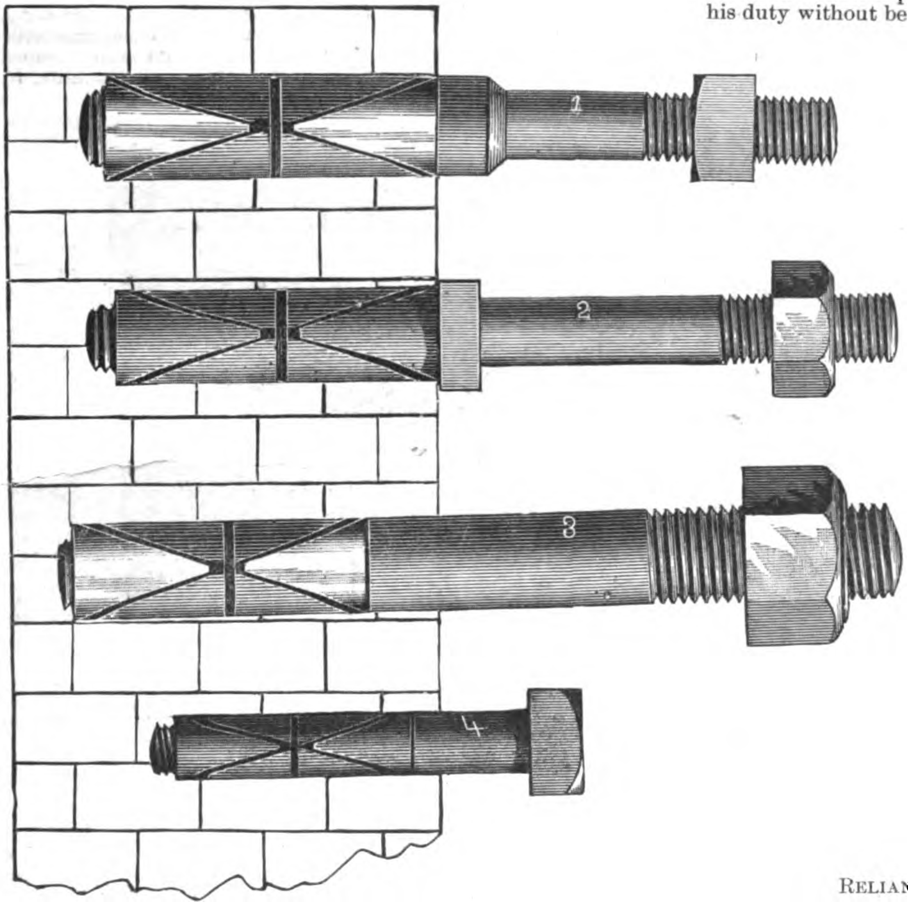
"THE FINANCIAL AND MINING RECORD," of New York, has increased its size to 32 pages, in which form it makes a convenient and valuable publication, and serves as a record and authority for the important fields to which it devotes special attention.

ELECTRIC MERCHANDISE CO.

Mr. Frank X. Cicott, formerly of San Francisco, who carried on a general agency business for eight years in that city, in the electric supplies and railway material, has assumed the management of the rail department of the above company, who are the selling agents in connection with their regular business for the Tramway Rail Company, Pittsburgh, Pa., manufacturers of girder, tram and T rails as well as street railway equipments generally.

AHLSTROM'S PATENT EXPANSION BOLTS.

In places where it is necessary to fasten and suspend wires from masonry and stone walls, it is very difficult to secure the necessary fastenings. The method now in vogue is to drill a hole, put in a tight-fitting wooden plug, saw it off so that it will be flush with the surface, and then drive a nail or screw into it. This is difficult and sometimes expensive. To avoid this, Mr. J. C. Ahlstrom, of Brooklyn, has recently invented the new expansion bolt shown in the accompanying illustrations. There are a great many places in connection with electrical construction works where a bolt of this kind can be used. All that is required with the expansion bolt is a hole of sufficient size and depth to insert it. Then by turning the head, as with a common bolt, the parts of the sleeve are drawn towards each other, which causes them to bind parallel in the strongest manner possible. It will also be seen that the greater the force brought on the bolt the tighter will be the grip. These bolts can be removed with ease and facility, and applied without injury either to the masonry or the bolt itself.



Ahlstrom's Expansion Bolts.

W. C. Boone & Son, 394 Broome St., this city, are the manufacturers. There will no doubt be a wide application of this bolt in connection with electrical construction.

THE WORLD'S FAIR ELECTRICAL EXHIBIT.

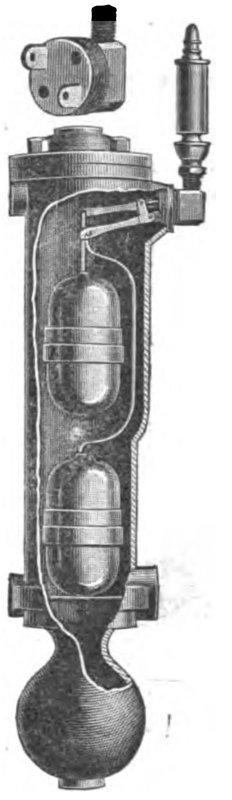
Professor John P. Barrett has made several changes in the classification of the department of electricity and electrical appliances at the Columbian Exposition, as arranged by Mr. M. H. De Young, whose arrangement he asserts is far behind the times from a practical point of view, although a good one scientifically considered.

THE RELIANCE SAFETY WATER COLUMNS.

The accompanying illustration represents an automatic high and low water alarm manufactured by the Reliance Gauge Company, of New York, Cleveland and Chicago. As will be readily seen from the engraving, a bell-crank lever connects the lower float rod with the whistle valve, and, with the water at the proper height, the solderless copper float attached to this rod is submerged, and, pressing upward, holds the valve closed, but when the water from any cause whatever, such as leakage, stopping of injector, breaking of pumps, or carelessness, gets low enough to rob the float of its support, it sinks of its own gravity, thus opening the valve and blowing a whistle.

The high water alarm is simply the low water alarm reversed. A bell-crank lever is turned over so that the weight of the float holds the valve closed until the water rises and carries the float up with it, thus opening the whistle valve. It is impossible for the water to pass either the upper or lower gauge cock without automatically blowing the whistle.

These appliances, which have been in use for over six years, are simple, complete, durable and accessible. There is nothing about them to get out of order and they have neither stuffing boxes nor fusible plugs. The fireman cannot seriously neglect his duty without being exposed by the whistle, and as a natural consequence he keeps one eye on the water all the time and carries it at the proper level, thereby saving fuel, repairs and stoppage, and prolonging the life of the boiler by protecting it from low water, while protecting the engine from high water. They prevent mistakes when the boiler foams, when the pump works poorly, when the water glass is stopped up, when breaking in new men, at night when the watchman is in charge, and in the morning when getting up steam.



Reliance Automatic Water Column.

S. H. PARVIN'S SONS.

Forty years ago the newspaper advertising agency of S. H. Parvin's Sons, 132, 134 and 136 Vine street, Cincinnati, was established, and the concern has recently been enjoying the congratulations of its numerous friends. It has handled the business of many advertisers continuously for a period of at least a quarter of a century, and bids fair to handle it for another 25 years; while its relations with a large number of technical and trade journals extend over a long series of years, with satisfaction and growing respect on both sides. The anniversary has been appropriately commented upon by the Cincinnati daily papers, whose complimentary remarks will be gladly echoed by all the periodicals with which the house has had dealings during its long and honorable career.

MAGNETIC VANE AMMETERS AND VOLTMETERS.

THE accompanying illustrations represent the latest improvements in station ammeters and voltmeters brought out by Queen & Co., among their "magnetic vane" instruments.

The construction of these instruments has been somewhat changed since they were first placed on the market; various improvements being incorporated which render them of even greater value as station instruments, although they have been largely used for such purposes as ordinarily made. The peculiarities of the "magnetic vane" ammeters and voltmeters, which are held to recommend them to electrical engineers are: low prices, absence of permanent magnets, accuracy, strong construction and handsome appearance.

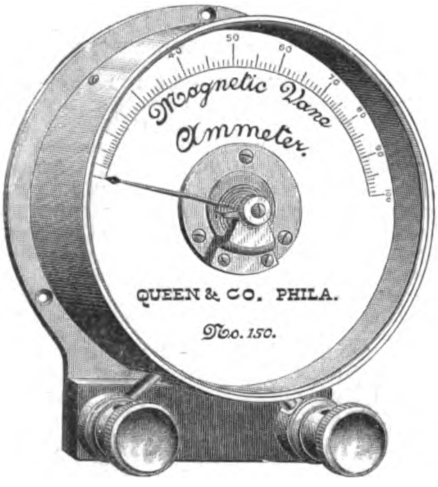


FIG. 1.—MAGNETIC VANE AMPEREMETER.

The "magnetic vane" instruments are not claimed to be absolutely accurate, but they are claimed to be quite accurate enough (within one or two per cent.) for commercial purposes. The instruments contain no delicate parts liable to injury, but are of good, solid construction, and in consequence are well adapted to the usage which station instruments necessarily receive. The voltmeters as well as the ammeters, can be left in circuit, and may be fastened permanently on the switch board if desired.

The "magnetic vane" instruments are designed especially for central stations, isolated plants, marine installations and railway work and are well adapted for general experimental work. For central stations the large size ammeters are used as they have fine open dials 8″ in diameter, and have special cut out plugs, so that they can be left in circuit, or not, as desired. They are made to measure currents of any desired quantity, though 500 amperes is the largest size in Queen & Co.'s catalogues. The smaller ammeters, Fig. 1, are suitable for isolated installations, and are so low in price that they can be economically used on the most inexpensive plants. In marine work, where space is limited, the ammeters and voltmeters must not be affected by proximity to the dynamos or the motion of the vessel. The "magnetic vane" instruments have been largely used for such work with most satisfactory results. The voltmeter, Fig. 2, is intended for electric railway engineering, and will be found a most valuable instrument. It is calibrated up to 600 volts, and has a special short circuit key for rapid work.

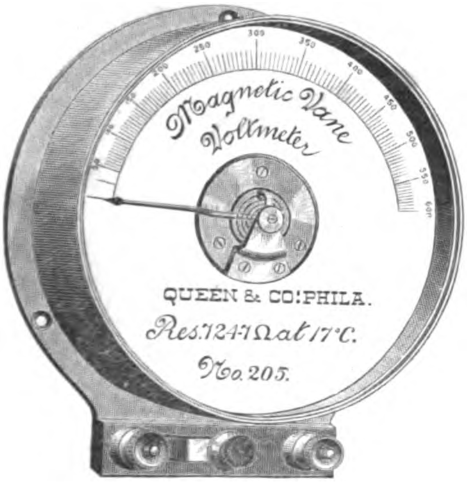

FIG. 2.—MAGNETIC VANE VOLTMETER.

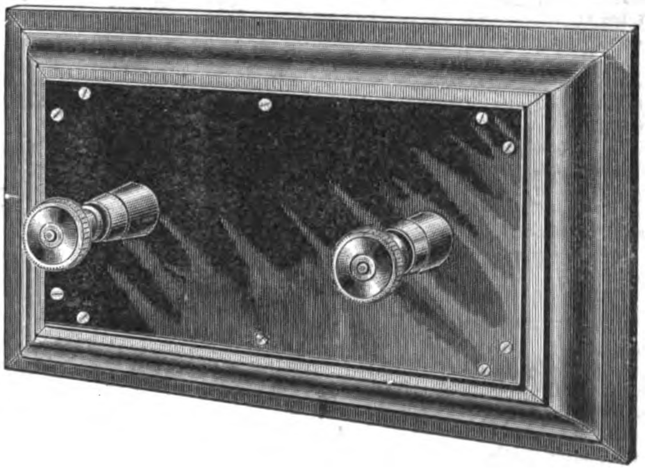
Queen & Co. have just issued their circular No. 235, fully describing their magnetic vane ammeters and voltmeters, and those interested in the subject will do well to send for a copy. It contains numerous testimonials supporting the claims made by the makers.

MEGOHM PLATES OF THE E. S. GREELEY & CO.

WITH the electrician whose duty it is to go about from station to station or from point to point, making tests wherever they may be required, the objection to the ordinary megohm box has not been simply that of expense. The question of ready portability has been a factor in deciding against the very high resistance box, notwithstanding its greater usefulness.

Now, however, with the advent of the English megohm plates shown in the accompanying illustration, a thoroughly handy, convenient and reliable megohm resistance is available at a much smaller cost than a one-tenth megohm wire box.

The portability of the megohm plates will be best appreciated upon taking into consideration the measurements and weight of the instrument. It is only 9 inches in length by 7 in width, and, exclusive of the binding posts, 2 inches in height. The binding posts, however, as is customary, stand 2 inches above the base of the instrument. The whole weight is about 3 pounds.



MEGOHM PLATE.

As evidence of the permanent character of the instrument, it is stated that Mr. David Brooks, of Philadelphia, has had one of them in use for ten years without any perceptible variation in the resistance, he having had it tested frequently at his laboratory throughout this period of time.

This instrument, though comparatively new in this country, is well known in England, where it has been in appreciative use for a number of years. It consists of a conductor of high resistance material, baked into plates of glass, which thoroughly protect the circuit from moisture, and the resistance of the instrument is not materially affected by atmospheric changes or temperature.

The employment of this high resistance instrument will permit of the same battery being used in making both the actual test and in taking the constant, and will thus reduce the opportunities for error that are otherwise apt to arise from the calculation of a battery ratio and from employing low resistance shunts as a consequence of the frequent practice of taking the constant through 10,000 and 100,000 ohms.

These standards range from 1 to 5 megohms, being calibrated as near to the unit as practicable. The definite resistance is marked on the face of each instrument in legal ohms, but the temperature, not being a factor, is unrecorded. The plates are mounted in polished mahogany cases with hard rubber tops and convenient binding posts.

This instrument is placed upon the market in this country by The E. S. Greeley & Co., of this city.

TELEPHONE PROGRESS is demonstrated by the fact that an exchange will soon be opened at Mandalay Straits Settlement. That at Cawnpore, India, is nearly ready to begin operations.

"ENGINEERING."

This is the name of a handsome new monthly periodical, the first number of which has just been issued for April from the offices, 124 World Building, this city. It is in octavo form and consists of 138 handsomely printed pages. There are a number of signed articles on engineering topics of interest, one by Mr. H. L. Webb, dealing with the possibilities, or rather the improbabilities of ocean telephony. There are also a number of well edited special departments summarizing the technical and engineering work of the month. The price is 25 cents per copy and $3 per year. The editor is Mr. J. R. Dunlap, who is to be congratulated upon this highly promising debut of the new magazine.

THE WOODBRIDGE & TURNER ENGINEERING CO.

The Woodbridge & Turner Engineering Co. has been organized as successor to the firm of Woodbridge & Turner, with Wm. S. Turner as president; Geo. A. Bell as vice-president, and J Lester Woodbridge, as secretary and treasurer. The company will occupy offices at 47 *Times* building, New York city, and to it will be turned over all new business of the firm, together with their entire stock of tools, supplies, apparatus, etc. It is their purpose to extend the scope of the business of the firm, in electric railway and electric light engineering.

The company will conduct a consulting and constructing engineering business. They will furnish plans, specifications, and estimates, supervise construction, and enter into contracts for the equipment of electric railways and electric light plants, in full or in part, including steam plants, line construction, track building, generators, motors, and cars. The company will be conducted under the same management as the old business, which was established with the building of the first commercially successful electric railway in the United States; and they feel that they bring to the company, together with their force of co-workers, a knowledge and experience equal to the demands of the business which has grown so remarkably.

It is the purpose of the management to retain the high standard of workmanship in all departments which it has heretofore been the endeavor of Woodbridge & Turner to sustain, and to merit a continuance of the good will and confidence which has hitherto been reposed in them.

A NOVEL ELECTRIC ELEVATOR.

The Keystone Electric Company, of Erie, Pa., have just completed a novel and ingenious electric elevator which they will shortly place upon the market. The details of the combination have all been worked out in the best and simplest manner, and possess many new and advantageous features which will at once commend it to those requiring such an outfit. The operation is very perfect, the motor being entirely free from sparking, heating, or other undesirable features which are a constant source of trouble when they exist. The motor handles the elevator by means of a belt from the pulley on the wind-shaft to that of the motor which only runs during the time that the platform is moving.

THE BOSTON TROLLEY AND ETNA INSULATORS.

Messrs. Albert & J. M. Anderson have entered into an agreement with the Engineering Equipment Company, of 78 Cortlandt street, New York, by which the latter Company become the representatives of the Anderson line materials, which include the well known "Boston Trolley," the trolley wire hanger, the "Etna" insulators, and all other materials for the equipment of electric roads, which are manufactured by the Messrs. Anderson.

The Engineering Equipment Company are the authorized agents for the sale of these excellent line materials, and the trade will be given the facilities and prices in all dealings they may have through this agency. The Engineering Equipment Company, who are now in temporary quarters, will remove during April to their new officers in the Central Building, foot of Liberty street, New York.

WESTERN TRADE NOTES.

THE ILLINOIS ELECTRIC MATERIAL CO., celebrated the opening of their spacious and handsome new store at 158 Fifth avenue, on April 1, in a very fitting and appropriate manner. All through the day a host of callers dropped in to congratulate the genial Messrs. Winston, Hoefer and Clark on their new quarters, and the thirsty ones found it was "no April fool's day there," after taking an observation of Mr. Ernest Hoefer's private office. It was whispered that the Baron had lined himself for the occasion with "canvas jacket."

MR. W. A. WILLARD, till recently connected with the Interior Conduit and Insulation Co., as their general sales agent, has associated himself with the Chicago office of the Edison General Electric Company as auditor.

MR. ALFRED M. WALTER has resigned his position with the Great Western Electric Supply Co., and accepted a similar one with the Illinois Electric Material Co., and will look after their metal-selling business. Mr. Walter is a pusher, active and energetic, well versed in the supply business, and both the company and himself are to be congratulated on the new connection.

MR. E. G. WILLINGHAM, the manufacturer of insulator pins, brackets and cross-arms, of Chattanooga, Tenn., was a recent welcome visitor to Chicago and returned south with his pocket-full of orders, large and small.

BUFFALO TRADE NOTES.

A NOVEL PULLEY COVERING.—A very reliable and inexpensive pulley covering has recently been brought out by the Burt Pulley Covering Co., 385 Washington street, Buffalo, N. Y. It is known as Brazilian gum pulley covering, and is applied by means of a brush to the pulley, four coats being put on. After the last coat is on, the gum is allowed to harden for 12 hours and then the face of the pulley is oiled with castor oil or any good belt dressing and the belt put on. This covering is guaranteed to prevent slipping of the belt and is as simple as it is efficacious. Numbers of pulleys have already been covered, among others those of the Rochester Electric Light Co. and the local Edison and Brush Co's, where it is giving the most unqualified and entire satisfaction.

A PROMINENT SUPPLY HOUSE.—The American Electric Supply Company, of Buffalo, N. Y., are doing a remarkably brisk business in general electric light and power supplies, and are also doing quite a large amount of construction work. They have just added a full line of combination fixtures to their stock, and are carrying a very complete stock of electrical apparatus of all kinds. Their growth, since starting in business, has been remarkable and is due to the careful and prompt attention given to their business. They have just doubled their capital stock, and are now in a position to handle as much business as any supply house in the country.

THE BUFFALO SPECIALTY MANUFACTURING CO., 67 Washington street, are placing upon the market a very excellent belt dressing, termed the "Electric," which is compounded upon scientific principles, and is highly beneficial to a belt. It contains no ingredients injurious to leather. The surface of a belt occasionally dressed with it is rendered smooth and glossy, transmitting largely increased power, keeping the belt pliable and in nice shape, and making it last very much longer. These are important features, and belt users should write for a sample.

NEW YORK TRADE NOTES.

THE TROY ELECTRIC DYNAMO CO., manufacturers of the Winkler dynamos for lighting and power, 535 River street, have perfected their apparatus and will be ready to place their goods on the market soon. Justice Miller is president; W. E. Hartwell, vice-president; Wm. L. Hall, secretary and treasurer.

THE ROBINSON ELECTRICAL WORKS, 478 Broadway, Albany, do all kinds of electrical construction and engineering work. They are to fit up the new Delaware and Hudson Canal Company's building at Albany, which, when finished, will be one of the largest and most complete buildings in that place.

MR. E. A. DUMM, of Chatham, N. Y., makes all sorts of castings. A recent visit to his foundry found him loaded up with business and working overtime to fill the orders he had on hand.

ZUCKER & LEVETT, 46 Murray street, New York City, deal in all sorts of supplies needed in electro-plater's work. They expect to have their Hercules motor ready for the market in the near future.

MR. A. T. BROOK, of 102 Chambers street, this city, is selling agent for the Uniform Drawn Steel Company, of Beaver Falls, Pa., who make a superior grade of steel shafting. They make the very smallest as well as all of the larger sizes.

ELIZABETHPORT CORDAGE COMPANY, 46 South street, this city make twine and rope which is used very largely in this industry. They manufacture a twine which is specially adapted for rewrapping of field coils of dynamos and motors. Wrapping the fields of a dynamo electric machine with twine is the best means of protecting it and they make a specialty of twine for this purpose.

DIEHL & CO., 385 Broadway, this city, who handle the Diehl motor fans are getting ready for the summer's work and Mr. F. H. Tobey, manager of this concern, anticipates a rushing business during the coming summer.

THE JOS. DIXON CRUCIBLE CO., of Jersey City, manufacture a belt dressing for leather belts which adds very much, to not only the life but to the effective working of a belt, as it prevents slip. This is a very good feature in running a dynamo.

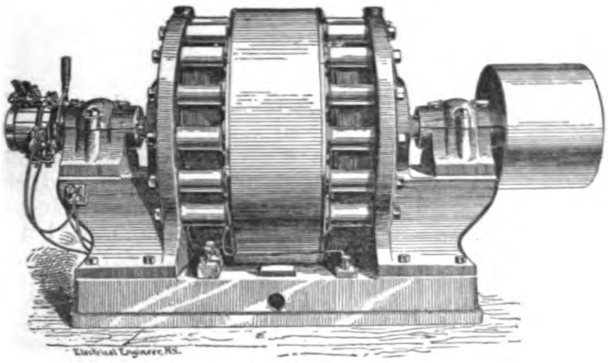
THE
Electrical Engineer.

VOL. XI. APRIL 15, 1891. NO. 154.

PROF. THOMSON'S NEW ALTERNATING GENERATOR.

OUR readers are already aware[1] that among the many devices upon which Prof. Elihu Thomson has been at work is an alternating machine in which no wire whatever is moved, the changes in the magnetic condition being brought about by a revolving multipolar magnet energized by stationary coils on either side of the axial core. This machine in its latest form is clearly illustrated in the accompanying engravings, Figs. 1, 2 and 3.

The alternater has recently been subjected to some preliminary tests at light loads by Mr. Ekstrom, of Prof. Thomson's laboratory, and the results obtained, which are given below, may, therefore, be subject to some revision when the tests are fully completed.



Electrical Engineer, N.Y.

FIG. 1.—PROF. THOMSON'S NEW ALTERNATOR.

The principal data regarding the construction of the machine are as follows :

Weight of machine, total	8,800 lbs.
" " separately excited field wire	440 "
" " series field wire	311 "
" " armature wire	93 "
Watts outputs per pound weight of dynamo	9 watts.
Power required for separately excited field	910 "
" " " series field	386 "
Resistance of armature	.008 ohm.

The loss in the armature conductor at a load of 75 amperes is 621.6 watts ; with an output of 79,500 watts, therefore, the electrical efficiency of the machine would be 97.65 per cent.

As stated above, the efficiency tests of the machine are not yet completed, but it has been run by a direct current motor without load and with its field excited, the losses in the direct current motor being known ; and the result shows that, adding the energy used in the separately excited field, and also the energy consumed in the series field, and the $C^2 R$ loss in the armature conductor increased 20 per cent. on account of the increased temperature, the machine will give a total commercial efficiency of about 93 per cent. which, it will be seen, is a very excellent result.

The estimate of efficiency given above assumes that the loss in the armature iron will be the same at light or full load, which, of course, may not be an actual fact. Dynamometer tests will shortly be undertaken.

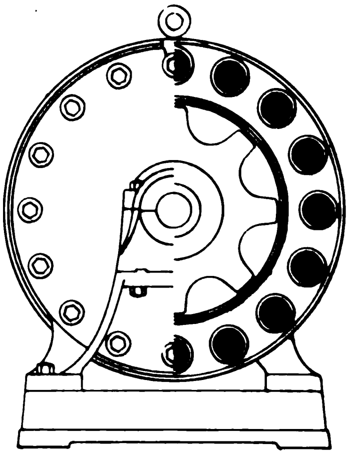


FIG. 2.—PROF. THOMSON'S NEW ALTERNATOR.

Among the mechanical features of the machine is that of interchangeability of the parts end for end, so that the pulley may be put on either end of the machine, the revolving body reversed in position in the machine, and the rotation of the machine made in either direction, without in any way affecting the conditions of output.

Prof. Thomson's high period type alternator, of which mention was made by him in these columns recently, is of the same design, but with 100 armature coils and 50 divisions in the revolving field poles. It gives 1,000 volts alternating potential. The type of machine is one which lends itself easily to the production of rapid alternations, as it only depends on the number of coils arranged around the revolving field pole and the number of divisions in that pole.

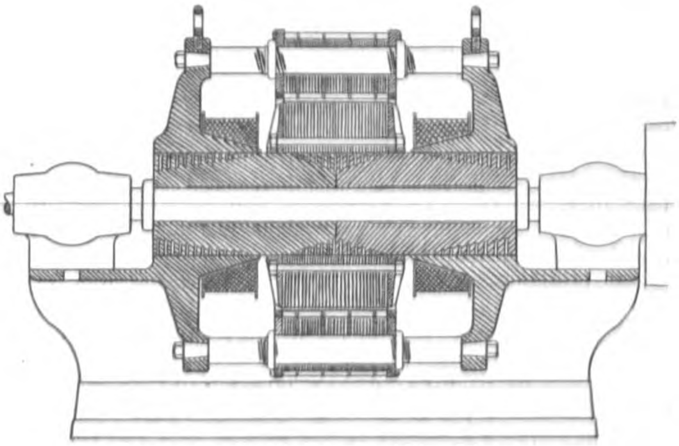

FIG. 3.—PROF. THOMSON'S NEW ALTERNATOR.

RULES AND FORMULÆ FOR INCANDESCENT LAMP WIRING.—III.

(Concluded.)

BY

Carl Hering.

WIRING FORMULÆ, THEIR DEDUCTION AND USE.

When a current passes through a wire, there is a gradual loss of voltage along the whole length of the wire. This loss, from Ohm's law, is equal to the product of the current and the resistance, that is,

$$E = C R$$

Now, the resistance of a wire is equal to,

$$R = \frac{l}{d^2} 10.605$$ [1]

in which R is in legal ohms, at about 75 to 80° F.; l is the length of the wire in feet, d is the diameter in mils (or d^2 the cross section in circular mils).

From these two formulæ it follows that

$$E = \frac{10.605\ C\ l}{d^2},$$

from which the loss in volts can be determined for any current, length and diameter of wire. As the circuit is usually a loop or return circuit, it is simpler to use the distance, or length of this loop, represented by D. Furthermore, as the loss is usually known, while the diameter is what is required, the formula reduces to the form

$$d^2 = \frac{21.22\ C\ D}{E}$$

in which D is the distance in feet, from the dynamo to the lamps or motor, for instance.

For arc light circuits this formula is in its simplest form, and for motor circuits also, after having first determined the current C, which is equal to 746 times the horse power divided by the voltage of the motor, or which may be found from tables.

For incandescent lighting this formula may be still further simplified by substituting the number of lamps n for the current C, in which case it is necessary to introduce the constant c, which is the current required by one lamp. This is usually multiplied once for all by 21.22 giving what is usually termed the "constant" for calculating the leads for that lamp. The formula then becomes

$$d^2 = n\ D \times \frac{(21.22 \times c)}{E},$$

in which the quantity in parentheses is the "constant" calculated once for all. This constant is then divided by the actual loss in *volts* E (not in per cent.), which gives a new constant, but for that loss only. The calculation is, therefore, as follows: *Multiply the number of lamps by the distance in feet and by the constant* (which constant has first been divided by the loss in volts). The answer is the cross section in circular mils. From a table find what gauge number this corresponds to, or from a table of squares or square roots, find the diameter in mils of which this is the square.

If lamps of different candle power (and therefore of different currents) are used together, it is best to reduce them all to the equivalent in one size, or else find the total current in amperes and use the original formulæ in which the current is used, instead of the number of lamps.

The loss is often given in per cent. instead of in volts. To find what this is in volts, it is necessary merely to multiply the voltage of the lamp V by the per cent. (in whole numbers, thus: 2 per cent.) and divide by 100. Or, to bring this all into the formula, gives

$$d^2 = n\ D\ \frac{(2122. \times c)}{\%\ V}$$

in which V is the voltage of the dynamo, and $\%$ is the loss in per cent. (in units, thus, 2).

Instead of giving the cross section in circular mils, namely d^2, the formula might be made to give it in square mils, but the very good practice of using circular mils instead of square mils, has become so universal, and is so much simpler, that the other is no longer to be recommended. To change the above formulæ so as to give the answer in square mils instead of circular mils, multiply the numerical constant by .7854, and change d^2 to a.

From the above explanation regarding the "constant" anyone will be able to calculate the constant for any make of lamp. It is always best to do this oneself, unless one is very sure what the constant, given by the makers, means. To determine the constant it is necessary to have the current required for one lamp; whenever possible it is best to measure this for a batch of 10 or 100 lamps, as the figures given by the makers are sometimes considerably below their true values.

---

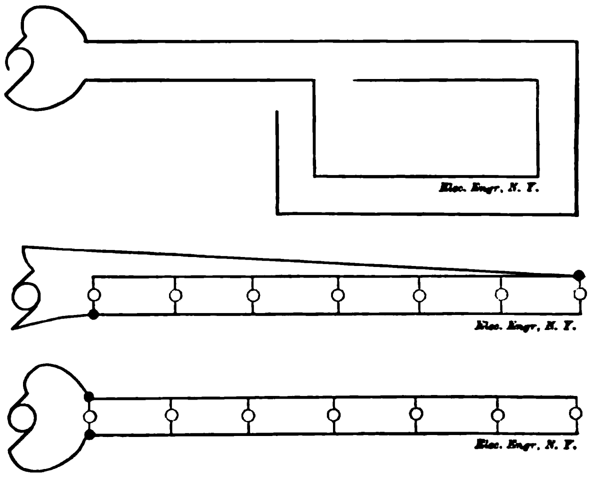
[1] This constant is in accordance with the new Matthiessen standard suggested by the Committee of the Amer. Inst. of Elect. Engineers.

RULES AND FORMULA FOR INCANDESCENT LAMP WIRING.

BY

Osborn P. Loomis

In an article by Carl Hering on the above subject, published in THE ELECTRICAL ENGINEER, of April 1, I observe a statement that needs correction. The author, in illustrating the various systems of distribution, and showing the several difficulties that are encountered, gives a diagram (Fig. 3), and states that all the lamps between this pair of leads will have the same potential. This diagram which is shown in the accompanying Fig. 1 will, on close inspection, resolve itself into the arrangement of Fig. 2, the dynamo leads being, of course, neglected. Now it is very evident that the middle lamp will get less potential than the end ones, and although this variation is much less than in the arrangement shown in Fig. 3, it could never be construed into uniformity. A little study will convince one that no system can be devised to produce that result in the sense of being theoretically perfect, although commercially they may be quite so.



FIGS. 1, 2 AND 3.

THE QUACKENBOSS DIRECT-ACTING ELECTRIC ELEVATOR.

About ten years ago, it will be remembered, Dr. Werner Siemens conceived the idea of operating an elevator by means of an electric motor carried upon the car and engaging, through a spur gear, a rack that extended from top to bottom of the shaft. This arrangement, although operative, was found to be very uneconomical on account of the excessive friction introduced by the gearing. A stationary motor, placed at the bottom of the shaft, or at the top, as is the present practice, while effecting an economy of power over hydraulic and steam elevators, yet, it is claimed, leaves unsolved what must ever be the problem of paramount importance, that of perfect safety.

It is a fact well-known to engineers that the moment a car is elevated, it is necessary to introduce an additional factor of safety—thus calling into existence safety clutches, friction clutches, etc. It is necessary to use several wire ropes attached to the hoisting cylinder or drum, and also to the counter-balance; in fact, large and progressive manufacturers have spared neither time nor money in their efforts to avoid accidents to the passengers using their conveyances, and the small record of such accidents, proves the success of their efforts.

The direct acting electric elevator, shown in the accompanying illustrations, is apparently the outcome of Dr. Siemens' experiments, but, on closer examination, will be seen to embody a totally different principle, being the invention of Mr. P. P. Quackenboss, of New York.

As will be seen, the motor A is suspended under the body of the car and is connected by a peculiar gear attachment to the gear-wheels, B. This motor is equivalent to about 3½ electric h. p., and by a simple method of switches, circuit breakers, etc., will move the car up or down or bring it to a stop. The motor, as shown, is attached to the under side of the car by bolts, mounted upon rubber gaskets to avoid vibration, and can be wound for any current and speed.

The gear-wheels, B, as shown in Fig. 2, grip the guy ropes in such a manner as to obtain the strongest grip with the least strain on the rope, and move up or down only when actuated by the motor through the gear. This adds still another factor of safety to those already in use, the gear being automatically locked whenever the motor stops, so that, if at any time the current is automatically broken, no further inconvenience need be feared than a stopping of the car.

Here another feature of the system comes into play, for, should such a stoppage occur, the attendant in the elevator simply attaches a crank to the gear and winds it up, or down, until a point is reached where the passengers can alight with comfort.

The guy-ropes, C, may be placed opposite to each other in the centre of the car or diagonally at the corners, and may be two or four in number, as desired, two, generally speaking, being sufficient for house purposes. They are kept taut by bolts at each end and are in reality flexible rails on which traction is secured by an increase of friction that does not greatly retard the speed.

Mr. Quackenboss' system thus has the advantage of adding two new elements of safety, in addition to which the apparatus takes up less room, and is claimed to cost less to install and maintain than any other system now in use. Where current can be obtained from a central station no engine or boiler are required on the premises.

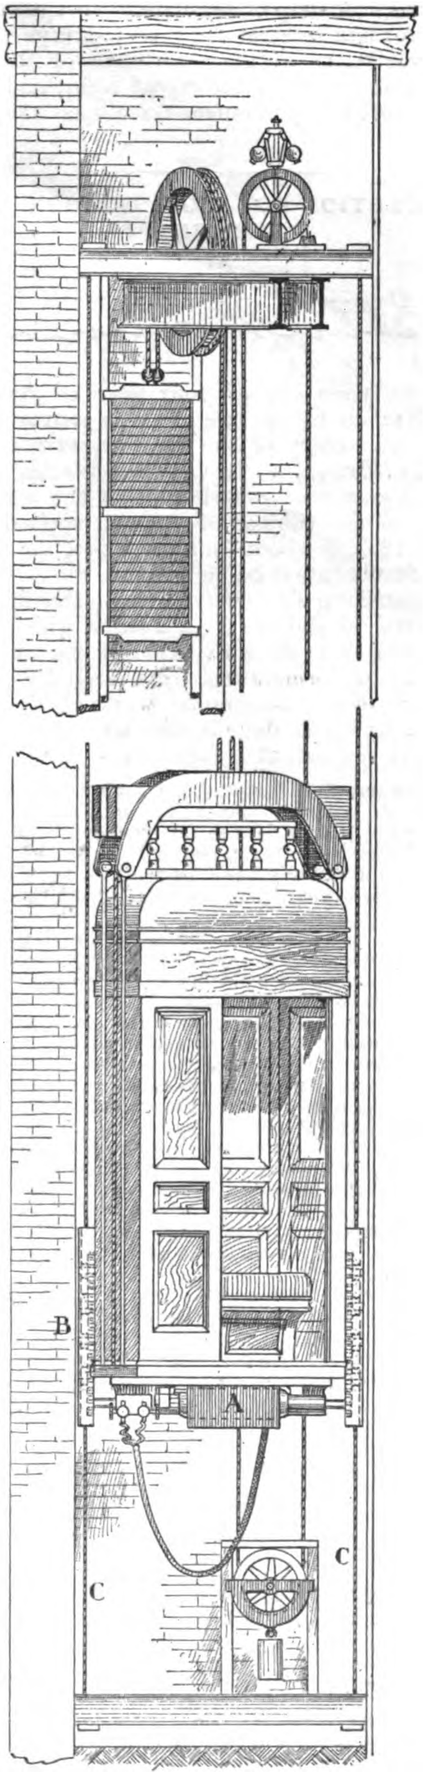


FIG. 1.—QUACKENBOSS' ELECTRIC ELEVATOR.

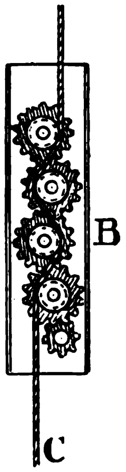

MICRO-SEISMOGRAPH.

PHOTOGRAPHIC registration has been advantageously substituted by M. Baratta for the mechanical apparatus hitherto used for the registration of the indications by the micro-seismograph of the vibrations of the earth. A microphone placed in the ground is connected to an ordinary telephone; the diaphragm of this receiving telephone is connected by an aluminum wire to a small plate of the same metal carrying a concave mirror movable around a horizontal axis. A strip of sensitized paper is uncoiled before the mirror and receives the reflected rays of a lamp. The small variations of the membrane of the receiving telephone are amplified by the ray of light, and the trace of this ray is left in a permanent trace upon the sensitized paper.

OIL INSULATION FOR HIGH TENSION TRANSFORMERS.

BY

Elihu Thomson

I notice on page 410 of your issue of April 8, that reference is made to the use of oil in converters, in connection with an account of the high pressure experiments of Mr. C. E. L. Brown, at the Oerlikon Works. It may be interesting to your readers to learn that the use of oil in converters was the subject of a patent applied for by me on May 9th, 1887, or about four years ago, the number of the United States patent being 428,648.

There is a striking similiarity between the figure of the patent referred to and the Figs. 2 and 3 which you reproduce describing Mr. Brown's experiments. I have used converters or transformers immersed in oil for quite a time past, and some of the commercial work of the Thomson-Houston Co. has been done in that way under my patent.

I quote from the patent as follows :—

> "The convective fluid for small coils may be air only; but I much prefer to use oil, preferably mineral oil of a non-volatile character, which is also an excellent insulator. Oils of the paraffine series are suitable, especially those of high boiling point. Paraffine wax may itself be used as the filling, as upon slight heating it melts and becomes fluid, acting thereafter as an oil.
>
> "A mixture of paraffine wax and mineral oil is good, for when cold it is buttery or semi-solid, but when warm, it becomes perfectly fluid and convective, while during the warming much heat is rendered latent by melting the paraffine present."
>
> "The immersion of the induction coil in such an oil gives great advantages in keeping out all moisture, in avoiding the necessity for other insulation on the copper wire of the coil than the cotton or other porous covering which becomes permeated by the oil, and in transferring heat by convection from the body of the induction coil to the external iron casting, by which latter it is, on account of the large surface exposed to the air, dissipated. Besides these advantages the casing may be so covered or slotted that it can be exposed to the weather without risking the insulation of the coils. Ventilated coil casings in foggy or very rainy weather so exposed may easily become leaky and cause, through access of moisture to them along with the entering air, a loss of insulation of the enclosed coil."
>
> "The casing which I use is, of course, inclosed or made tight, or is suitably constructed to prevent escape of fluid or access of water. When the coil is placed in it the whole is heated to the boiling point of water, or a little above, to drive out all moisture from the casing and enclosed coil, and cause the oil to throughly permeate the spaces."

CONVERTING AN ARC LIGHT PLANT INTO AN INCANDESCENT PLANT.

BY

Harry Alexander.

The conversion of an arc light plant into an incandescent without altering the dynamo in any way, which was recently carried out by the writer, may prove of interest to the readers of The Electrical Engineer.

Shortly after arc lighting was introduced, the firm of J. B. & J. M. Cornell introduced the electric light in their large iron works in New York city, for which purpose the Weston machine was installed. This machine, of 10 arc lights capacity, was at that time built with 12 coils, and generated a current of 20 amperes at 300 volts. On account of the peculiar construction of the building and the nature of the work carried on in the shops, it was deemed necessary to secure a more even distribution of light, and to secure this end, it was determined to introduce incandescent lamps, but to retain the dynamo, if possible.

The change was successfully carried out, in the following way. Bernstein series lamps were substituted for the arc lamps and run in five branches, with eight lamps in series in each branch, making 40 lamps in all.

The lamps, which take 4 amperes and are of 50 c. p. each, are run in double rows in each of the four sections in the shops, each section being 50x250 feet; making the lamps on the average about 25 feet apart and about 15 feet high. Each lamp is supplied with a 19 inch enameled reflector, which throws a bright, steady light in all directions over the full area illuminated. The lamps are easily controlled by a safety branch board at the main line. The wiring is run on porcelain insulators throughout, Okonite wire with braided insulation being used.

The change in the method of illumination has met with the general approval of the workmen, and a second, larger machine, will soon be changed over to the new method of illumination.

MUNICIPAL ELECTRIC LIGHTING PLANTS.

BY

M. J. Francisco

The April 1st number of The Electrical Engineer reproduces and criticises the familiar list of cities owning municipal plants. This list has proved a veritable will-o'-the-wisp, leading its votaries deeper and deeper into the labyrinths of political necromancy. It has been used by the advocates of municipal ownership in every case where the question of street lighting has been heard, and special stress is always laid upon the remarkable results achieved in Chicago.

I have shown in these columns, and also before the Committee on Manufactures of the Massachusetts Legislature, that the statements made by the superintendent of lighting in Chicago and other places were incorrect and could not be sustained. What an anomaly, that men who claim to be working for the good of mankind, should inaugurate their reform by a scheme of concealment in regard to the true cost of the lights! Experience has demonstrated many times that nothing is gained in the end by this kind of subterfuge. If the lights can be produced by city authorities at less price than private companies can furnish them, show it fairly and plainly by giving the full cost and facts, and there is not a man connected with the electric lighting business who will not cheerfully acquiesce in and approve of municipal ownership. But when a large share of the cost of producing the light is charged to other departments and the true cost concealed, and the private corporations branded as "grasping monopolies" because they do not furnish the light at such price, it looks as though it was political jugglery, instead of political economy.

The writer, at the Cape May convention, proved conclusively that $69.35 per lamp per year was not the true cost of Chicago's electric lights. The annual report of the comptroller of Chicago, signed and sworn to February 20th, 1891, throws still more light upon the subject of electric lights in that city and indicates that the statements that have been made by the superintendent of lighting were anything but reliable. The superintendent, in his report to the comptroller for the year ending Dec. 31, 18 0, says: "The present cost of operating 900 arc lights, at $83 each per year, is $74,700, or $2,280 in excess of the amount paid for the gas these displace." When we consider, that of the four stations furnishing these lights, District No. 1 only commenced operations December 24th, 1890; District No. 4 commenced February 22nd, 1890; District No. 6 commenced March 17th, 1890, and District No. 8 commenced operating May 26th, 1890, not one of them for a full year and No. 1 station only for seven days during the year, we are led to wonder, if the lights only cost 19 cents per night, why the superintendent should call upon the city to pay $83 per lamp and also for the full year.

An examination of the comptroller's report gives us still more suggestive figures. On page 76, it says, the "increase in the value of the electric light plants from January 1st, 1890, to January 1st, 1891, was $96,764.96," while on page 59 it is stated that the city "paid for electric light plant and maintenance of same, $229,569.42." Now, if as is shown on page 76, only $96,764.96 was used for increasing plant, the cost of running the lights was $132,804.46, being $147.56 per year for each lamp (running a full year) and this does not include interest, depreciation, taxes, water rent or insurance. As none of these lamps burned a full year (No. 8 station was in operation only seven months, and No. 1 station only seven days during the year), of course the cost to the city was more than this price per lamp. These figures are taken from the statement of finances of the city of Chicago and are sworn to; therefore we may rely upon their correctness.

The city has already expended $526,184.47 in electrical plants and apparatus for four stations, and the superintendent of lighting says the expenses to be incurred in 1891 for increasing these four stations will be $282,186; and on page 20 of report the comptroller says "the cost of the public lighting steadily increases." On the same page of this report the statement is made that claims for large damages have been filed against the city by property owners on account of the viaducts, and that "even under the most favorable results there will be large sums which the city will be obliged to pay sooner or later." It may be the superintendent meant the lights cost $19 per night instead of 19 cents; it certainly would have been about as near the truth.

Here is the practical result of a municipal plant, as shown by the official reports and records of the city. Still, in the list which is being circulated broadcast by the advocates of municipal ownership, we are told the electric lights in Chicago only cost the city $55.60 per lamp per year. *O Tempora! O Mores!*

NALDER'S BALLISTIC GALVANOMETER.

A good deal of inconvenience sometimes attends the use of the ordinary form of control magnet in a galvanometer. This arises from its being really required to perform two distinct functions; first, to alter the strength of the field acting on the needle system, and, secondly, its direction; the former determining the sensitiveness of the instrument and the latter the zero position of the needle. When altering the one it is difficult to avoid altering the other, and the inconvenience becomes the greater, the slower the swing. The form of control shown in the accompanying illustrations was suggested by Dr. R. Mullineux Walmsley, of the Heriot-Watt College, Edinburgh, who wished to more or less avoid this double effect of the magnet. The usual one is replaced by the much smaller one, A, Fig. 1, as fixed on the top of the case, and which can be turned round, but not raised or lowered. By it the spot is first brought to zero. The combined field of the earth and A are then diminished (or increased if a quick swing is required) by turning the tail magnet B on its shaft, or bringing it nearer or further off; but it will be observed that, from the symmetrical position of this magnet with respect to the needle system, when thus moved or turned, it merely alters the intensity of the field without interfering with its direction. Any slight shifting of zero which may occur, due to want of absolute symmetry, is adjusted by a very slight movement of A.

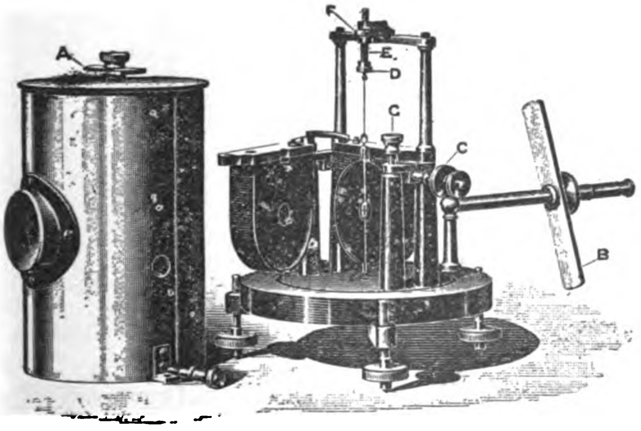

FIG. 1.—NALDER'S BALLISTIC GALVANOMETER.

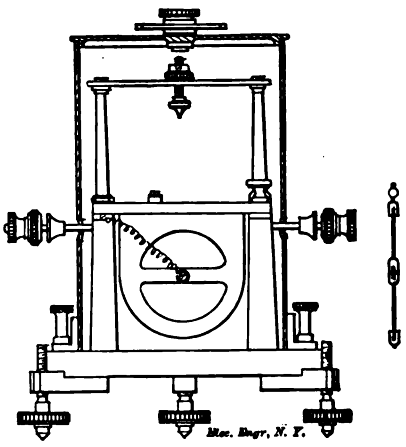

FIG. 2.—NALDER'S BALLISTIC GALVANOMETER.

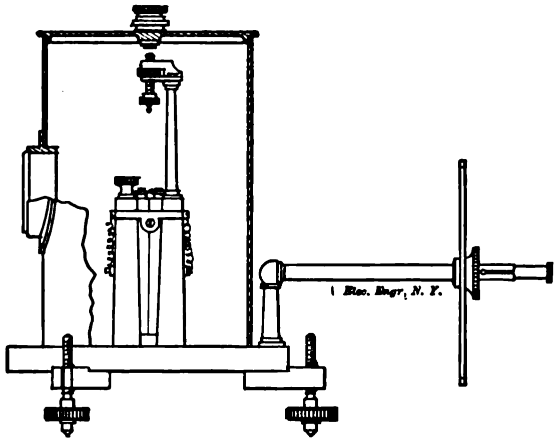

FIG. 3.—NALDER'S BALLISTIC GALVANOMETER.

Messrs. Nalder Brothers & Co., of London, have applied this method of control to ballistic galvanometers. There are one or two details about this pattern that may be noted. The whole cell is supported on ebonite pillars, and the terminals screw into plates in these after the cover is on, passing through holes in the latter, which are closed by sliding ebonite plugs, C, to keep the dust out when the instrument is not in use. The front coil is hinged so that the needle system is left clear in case a new fibre is required. The attachment for the fibre, D, is free to turn on the end of the rod, E, so that torsion can be taken out; D itself is threaded, and raised or lowered by the nut F, but has a longitudinal slot in it in which a pin works, so that the rod cannot turn round. The second connection to the front coil is through the clamping screw G, which holds the coil in place when closed. In Figs. 2 and 3, the instrument together with the needle system with its heavy bell-shaped magnets is shown in detail.

WHAT ARE THE LIMITS OF HIGH POTENTIAL TRANSMISSION?

BY

Chas. Steinmetz.

In the last number of The Electrical Engineer, I noticed Mr. A. Schneller's criticism of the project to transmit 300 h. p. by alternating currents of 30,000 volts pressure over a distance of 115 miles. As Mr. Schneller's rather unfavorable remark, "technical impossibility," might perhaps influence the opinion of many engineers against the advisability of power transmission under such pressures, I deem it proper to show the fallacy of Mr. Schneller's conclusions. Of course, everyone will acknowledge that the use of 30,000 volts pressure will bring about difficulties not met with in usual practice, and quite some experience will have to be gathered; and even partial failures are to be expected, before Niagara Falls water-power will light New York's streets, and drive the shafting in its factories.

But to come to Mr. Schneller's criticism, it is neither unsafe nor difficult to build reliable transformers for pressures of 30,000 volts and even more, because every large Ruhmkorff spark coil generates hundreds of thousands of volts. We must only bear in mind then, that for such pressures air-spaces can no longer be considered as insulators. Hence we have to enclose the whole transforming apparatus in a medium of better insulating qualities, as was done with the oil-transformers used in the Oerlikon experiments.

The leakage-current through the oil insulators of the line conductors, is considered even by Mr. Schneller as unimportant. I consider it of still less importance, because I hardly think that Mr. Brown had the best possible oil-insulators for his tests, and so I think that even the 3.2 per cent. loss referred to, will be essentially reduced.

Mr. Schneller considers the charging loss in the oil-insulators as the principle one, and calculates an enormous value for it, while the Oerlikon experiments, even when using a pressure higher than 30,000 volts, and a number of insulators equivalent to quite a considerable part of the proposed line between Frankfort and Lauffen, showed no perceptible charging loss No one, up to the present, in designing insulators, has paid any attention to their static capacity, for the very simple reason that this capacity has thus far been without importance. If condenser capacity of insulators should show any influence in practical working, it will be an easy task to build insulators with the least possible capacity, just as telephone cables are built for least possible capacity, this being essential for their effective working.

Then Mr. Schneller gives figures of charging losses without giving the number of periods per second employed; but the charging loss is directly proportional to the number of periods, and therefore by reducing the number to, say one-fourth, it would be decreased by 75 per cent. while generators and transformers of a size fitted for use in such large power transmissions will work just as economically as with higher frequencies, and motors even more economically.

Furthermore, with regard to the silent discharge which Mr. Schneller charged with a loss of 20,000 watts, everybody who ever handled a static electric machine, for instance a Töpler-Holtz, which gives pressures far in excess of 30,000 volts, knows that by simply covering the conductor with an insulator such as india rubber, the brush-discharge from the rubber covered parts disappears almost entirely.

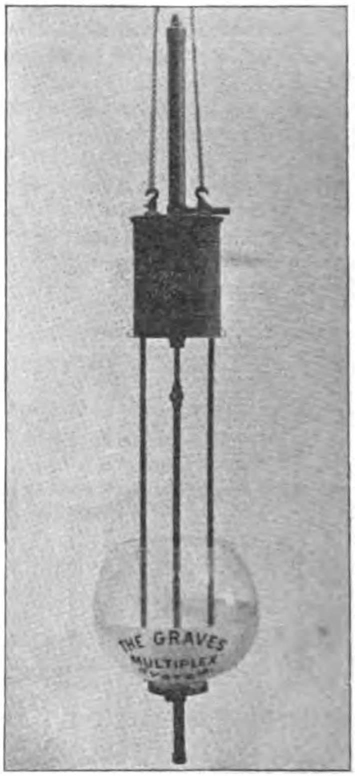
Therefore, these two large losses which to Mr. Schneller seem to prove the project a technical impossibility, can exist only in a line improperly built and poorly insulated; but by proper care in the construction, they can be made so small that they may very likely be entirely neglected.

One word more about the telephone disturbances. These disturbances are proportional to the current flowing in the line, and entirely independent of the pressure, so that a given current always gives the same disturbance, no matter whether it is backed only by a few volts or forced ahead by hundred thousands of volts. Therefore every increase of pressure will materially reduce the telephone disturbance by reducing the current needed to transmit the power.

Therefore I consider a power transmission by means of such a pressure not at all as impracticable, nor 30,000 volts as the highest pressure possible to use, but consider it only as the second step in that direction, the first of which was taken by Ferranti by sending 10,000 volts into his primary mains; and I do not believe in any limit of pressure possible with the alternating current, but, on the contrary, that in the not distant future we shall see power transmissions for long distance railways, etc., working under a pressure of even hundreds of thousands of volts and working safely and satisfactorily.

THE GRAVES ARC LAMP.

The Graves multiplex single carbon arc lamp shown in the accompanying illustration, is the invention of Mr. W. D. Graves, of Cleveland, O., who has made the subject of arc lamps a special study for the past nine years.



The Graves Multiplex Arc Lamp.

The lamp does not contain any clock work, dash pots, or springs, and when once adjusted to a certain quantity of current, never needs changing. The clutch has a long bearing upon the rod and is so made that, should the rod become slightly worn it readily adjusts itself and prevents slipping.

These lamps are at the present time working very successfully on 110, 220 and 500 volt circuits, and also on 6.5, 8, 9.6, 10 and 18 ampere constant current circuits.

Thus it is obvious that it can be made to suit any of the standard currents and to use 1, 2, 3, 4, or, in fact, any number of sets of carbons in succession; and in order to do this it is not necessary to add any complicated mechanism.

The designer has arranged the construction of this lamp to meet the convenience of both the trimmer and the repairer, making it possible for an ordinary workman to take it all apart, clean, assemble and adjust it in the shortest possible time.

The lamp, when constructed for constant current circuits is provided with two positive automatic cut-outs, one, which provides for the failure of the lamp to feed, and another, to protect the circuit when the carbons are entirely consumed. This latter cuts the lamp out through no resistance, thus saving the power required to maintain the current through the resistance of the other cut-out coils. It will thus be seen that it is practically impossible to burn out either of the coils, or any other part of the lamp.

When two or more sets of carbons are used, the action of the succeeding set does not depend upon the consumption of the former, for should the rod become hung or in any way prevented from feeding, a succeeding set is instantly thrown into circuit, and the other cut-out. The lamp presents a very neat appearance, is light in weight, having steel side rods of only sufficient strength to keep it in perfect allignment, and at the same time being so small that the shadow from them is brought to a minimum.

THE EFFECT OF INVENTION UPON THE PROGRESS OF ELECTRICAL SCIENCE.[1]

BY PROF. C. F. BRACKETT.

ELECTRICAL science really begins with the labors of Dr. Gilbert. These he published in 1600. For almost exactly two hundred years investigation was confined to that domain which is still sometimes called static electricity. A new era, however, dawned in 1800 when Volta gave to the world an invention whose importance can scarcely be exaggerated—the voltaic battery.

The simplicity of the device and the wonderful effects which it could produce at once excited the most lively interest, and men of science made haste to investigate it. By means of it Carlisle and Nicholson soon succeeded in decomposing water, and Ritter had a similar success with copper sulphate. Thus commenced a long line of research in electrolysis which was pursued with great success by Davy and others, and which finally led Faraday to the grand generalization known as Faraday's laws of electrolysis.

Meantime Ritter had noticed that the two plates of the same metal which have just served to convey the current to and from a liquid while undergoing electrolytic decomposition can, of themselves, furnish a current, and he was thus led to the invention of the "storage battery." It was Volta, however, who gave the correct explanation of its action.

Ritter, Pfaff, and others observed that the conducting wires of the battery are warmed by the passage of the current, and Curtet, on closing the circuit with a piece of charcoal, produced a brilliant light. Davy systematically investigated these heating effects of the current, employing various metals as conductors, and finally in 1812, on making the current pass between two pieces of charcoal he produced the well-known arc.

Thus, in little more than a decade from the date of Volta's invention, more real progress was made than in any century previous. But the true progress of electrical science is not to be measured solely, or even mainly, by the number nor by the splendor of the physical results which attend it, but rather by the insight into the operations of nature which we gain. Viewed in this light, Volta's invention was itself the embodiment of a great advance which he had made into an entirely new region. It was not the mere outcome of happy accident, but the result of severely logical reasoning upon facts which he had observed while he was investigating the so-called "animal electricity" of Galvani.

Volta's fundamental research respecting the electrical disturbances, produced by contact of dissimilar substances, afforded him a basis for a rational theory of the action of the battery, and this theory has had a far-reaching influence not only upon the progress of electrical science but on physical science in general.

The voltaic battery rendered possible an observation, out of which grew the next great invention which we will consider. In 1820 Oersted noticed that a magnetic needle was deflected from its normal position by voltaic current which was flowing in a conductor near it. He determined the relation of the current to the deflection as respects direction, and sent a brief memoir concerning the matter to well-known scientists.

Arago immediately found that iron filings were attracted by a wire conveying a voltaic current. In order to strengthen the magnetic action of the current, Schweigger invented the magnetizing helix or spiral. By means of this Arago was able to magnetize steel permanently and iron temporarily. The conception of this helix was the first act of invention which was to produce the electro-magnet. Yet, it was not until 1825 that Sturgeon wound a conducting wire about a core of iron to produce the electro-magnet proper. The magnet, as it left the hand of Sturgeon, was a crude device, which the genius of Henry finally perfected between the years 1828 and 1831. Henry constructed several magnets, some of which were wound with long, thin insulated wires, while others were wound with shorter and thicker wires in parallel. These could be joined either in series or in parallel. He thus had the means of studying the effects which a given battery can produce when made to actuate magnets having different windings. He also investigated the effects which are produced by the use of batteries having different electro-motive forces. He thus discovered the principles which must be observed in order to secure the best results from the electro-magnet under any given conditions. Indeed, a careful examination of Henry's work will convince one that he disclosed the same result by the light of skillful experiment, as is set forth in Ohm's now well-known formula. Moreover, he clearly perceived that the magnet, as he had perfected it, offered the solution of the problem of the telegraph, and he made proof of his prevision by actually installing one.

In the hands of Ampere the conducting helix was made, under one form or another, a means of investigation which he pushed with wonderful energy and skill until he unfolded the laws of interaction between magnets and electrical currents, as well as those which govern the mutual actions of the currents themselves. In short, it may be said that as the result of his inquiries, Ampere was brought to a comprehensive theory of magnetic action which was startling alike for its simplicity and its boldness. It deserves to rank with Newton's theory of universal attraction.

The skillful labors of Faraday and Henry brought to light by the same means, the laws of induced currents, and so supplied the elements which practical inventors have since combined so as to do our bidding, whether it be to illumine our streets and dwellings, push our cars, or delve in the mountain for hidden treasure.

The electro-magnetic phenomena educed by the voltaic current as it flows through a helix, constitutes the basis of a most admirable system of measurement for electrical quantities, while the helix itself contains, in germ, the whole family of measuring instruments, by means of which such measurements are made. Moreover, these phenomena led the sagacious mind of Faraday to a wholly new way of regarding electrical action in general. He clearly perceived that the old doctrine of the "imponderables" was untenable, and he looked for some common nexus between all physical actions. He was disposed to refer the interactions which bodies exhibit in consequence of their electrical states, to the medium intervening between them. As light is believed to be transmitted by a universal medium, he sought to find, by experiment, some connection between light and electro-magnetic action. On passing a beam of plane polarized light through a block of glass within a magnetizing helix, he found that the beam was twisted when the current was made to flow through the helix.

Maxwell undertook the very important work of subjecting the results reached by previous workers, and generally set forth in Faraday's "Experimental Researches" to mathematical discussion which must be considered the final test of truth. Not to mention others, one very important result was his "electro-magnetic theory of light." But experiments were wanting, save the single one of Faraday, just mentioned, to confirm his deduction. It was reserved for Hertz to supply the necessary evidence in support of Maxwell's theory, which he has lately done by making skillful use of the oscillating discharge of charged conductors, earlier demonstrated by Henry.

Thus it appears that the two great germinal inventions which have most influenced the progress of electrical science, during our century, are the voltaic battery and the magnetizing helix. The one gave us first the means of evoking electrical energy continuously, while the other gave us the means of applying it as we might have occasion. Both contributed powerfully in a direct way to the progress of electrical science, by reason of the various and startling phenomena which they revealed.

But it seldom happens that progress continues long in any department of physical science unaffected by the practical application of its results in the arts, and, conversely, such applications almost invariably react to stimulate scientific inquiry. Two principal reasons for this effect may be noticed. When the apparatus and the operations of the laboratory give place to those which are suited to commercial uses, new conditions arise which frequently bring into prominence phenomena before unobserved or inconspicuous. These then become subjects for new investigations and in due time scientific progress is the result. Thus telegraphy brought its knotty problems as well as its successes, especially when its lines were stretched under the sea and when one wire was required to do the duty of several, and nothing less than the highest skill and the most severe analysis has sufficed to effect their solution. So, too, telephony was early beset with peculiar difficulties, notwithstanding the simplicity of the means which it employs, thanks to the genius of Professor Bell; but they were such as electrical science has profited from. Speaking generally, it may be said that almost every one of the devices which are in daily use for the transformation of mechanical work into electrical energy, and the converse, has compelled its inventors, in the course of its evolution, to contribute something to the common stock of scientific truth.

---

[1] A paper read at the Patent Centennial Celebration, Washington, April 8, 1891.

It was regretted by Franklin that the results of electrical research had not been turned more to the use of man in practical affairs. Faraday did not doubt that the time would come when that reproach would be removed, but he felt that it was a duty on his own part to push on the work of discovery, and to leave industrial inventions to others. Such applications are now everywhere about us and are rapidly extending. Of course they involve the investment of millions of capital, and this renders it impossible that the great public shall be indifferent to the science upon which they depend. Hence it is that all our schools of technology and most of our colleges have already made provision for training in it.

Every consideration leads us to expect that future progress in electrical science will be more rapid than it has ever been in the past; the present offers to the student the accumulated treasures of knowledge and the hope of scientific distinction as well as that of pecuniary reward. It can hardly be that among the scores of young men to whom these advantages come as inspirations, there will not be found some who shall prove to be worthy successors of the great men into whose labors they so easily enter.

A CENTURY OF PATENT LAWS.[1]

BY JUSTICE S. BLATCHFORD, U. S. SUP. COURT.

I have been requested by the committee which has charge of the ceremonies of this celebration of the beginning of the second century of the American patent system, to address you on the subject of "A Century of Patent Law."

As we derive the principles of our statutory and administrative patent law from England, it seems proper to regard the subject as covering English patent law, to a certain extent.

Prior to the English statute of 21 James I., chapter 3, passed in 1623, entitled "An act concerning monopolies and dispensations with penal laws and the forfeiture thereof," commonly called "the Statute of Monopolies," it was customary for the King, by virtue of his prerogative, to grant exclusive privileges or monopolies to individuals according to his pleasure, and not because of any invention or discovery which the individual had made, or had been the first to introduce into the kingdom. To such an extent was this carried, that Edward III. granted to two persons a patent of privilege for the sole making of "the Philosopher's Stone;" and, by subsequent sovereigns, patents were granted for the sole manufacture of playing cards, and for an exclusive right to sell various necessaries of life.

By the Statute of Monopolies, all monopolies were abolished as contrary to law, excepting grants to the first inventor of any manner of new manufacture, of the sole privilege of working or making the same. The statute did not bring such grants into existence, but excepted them out of the grants of monopolies, and left them to depend upon the common law for their legality.

James I. in 1610 had made a public declaration that all grants of monopolies and of the benefit of any penal laws, or of power to dispense with the law, or to compound for the forfeiture, were contrary to the laws of the kingdom, and had commanded that no suitor should presume to move the King for matters of that nature.

Section 1 of the Statute of Monopolies declared that all monopolies theretofore granted, or thereafter to be granted, for the sole making or using of anything, should be void. Section 6 of the act provided that the inhibition should not extend to a patent of privilege "of the sole working or making of any manner of new manufactures within this realm to the true and first inventor" thereof, which others at the time of making the grant "shall not use, so as also they be not contrary to the law, nor mischievous to the State, by raising prices of commodities at home, or hurt of trade, or generally inconvenient," their duration to be for 21 years from their date, in respect to patents theretofore granted for more than 21 years, and to be for 14 years or under in respect to patents thereafter to be granted.

For many years after the passing of this statute, the arts and manufactures continued in a low state in England, and few of the inventions patented were of any value. Until the reign of George III., the law reports are almost entirely silent respecting patent privileges; and almost the only case reported during that period is that of *Edgeberry and Stephens*, (2 *Salkeld*, 447,) where it was held, construing the statute of 21 James I., that "if the invention be new in England, a patent may be granted, though the thing was practiced beyond the sea before; for the statute speaks of new manufactures within this realm; so that if they be new here, it is within the statute, for the act intended to encourage new devices useful to the kingdom, and whether learned by travel or by study, it is the same thing."

Since that decision, it has been the uniform practice in England to grant letters patent to a person who introduces an invention not used before within the kingdom; and Parliament has repeatedly recognized the principle, by granting exclusive privileges to such introducers.

The first case of importance respecting a patent was an action of *scire facias* brought against Sir Richard Arkwright, (*The King* v. *Arkwright*, 1 *Webster*, 60,) to repeal his patent for an invention of a machine for preparing material for spinning, which action was tried in June, 1785.

About ten years afterwards, the important cases of *Boulton and Watt* v. *Bull*, (2 *Hen. Black.* 463,) and *Hornblower* v. *Boulton and Watt*, (8 *Term R.* 95,) in regard to the great invention of James Watt in steam engines, were tried, in which the patent law was much discussed, and many of its difficulties and obscurities were cleared away. In the second of the above cases, the patent granted to Watt in 1769 was held by the Court of King's Bench to be valid. Since that time the issue of patents for inventions has increased steadily, the interests involved in them have assumed immeasurable importance and magnitude, and the principles of law applicable to them have been developed and applied by judicial decisions of the highest value.

In 1765, the idea occurred to Watt that if the steam were to be condensed in a vessel distinct from the cylinder, it would be practicable to obtain a low temperature of condensation, and still keep up the temperature of the cylinder. For that purpose he provided a separate vessel into which the steam from the cylinder entered, which vessel was to be kept cold either by injecting cold water into it or by letting cold water fall over the outside of it, and so a vacuum could be maintained in the separate vessel. Thus the steam which passed over from the cylinder would be condensed, the pressure in the cylinder would be as low as the pressure in the condenser, and the temperature of the metal of the cylinder and piston would be kept up, since no cold injection water would come in contact with them. On putting the apparatus to a test, it operated as was expected; and, to maintain the vacuum in the separate condenser, Watt added an air-pump to remove the condensed steam and injection water, with any air that might gather in the condenser.

He added several subsidiary inventions, such as more tightly packing the piston, closing the upper end of the cylinder, enclosing the piston with a steam-tight stuffing box on top of the cylinder, causing steam instead of air to press on top of the piston, casing the cylinder in a non-conducting material; and introducing a steam-jacket between the cylinder and an outer shell. All these features were specified in his first patent, which was obtained in January, 1769.

By an act of Parliament passed in 1775, that patent was continued for 25 years, and Watt, in connection with Matthew Boulton, who owned some engineering works at Birmingham, entered upon the manufacture of steam engines. At first the only application of the engine was to pumping water from mines, but Watt soon made other inventions to fit the engine for other uses, and took out further patents in 1781, 1782 and 1784. These inventions covered the method of converting the reciprocating motion of the piston into a rotary motion, so that ordinary machinery could be driven, making the engine double-acting by putting both ends of the cylinder in communication alternately, with the boiler and the condenser, instead of only one end, introducing the system of the expansive working of the steam, instead of admitting it through the whole stroke of the piston; and the well-known parallel motion.

Watt's principal patent was sustained by the courts of England, and he enjoyed the fruits of it until it expired in the year 1800. To his great invention we owe the development of the steam engine as used now for traffic and transportation by water and land; for, without it, there could be no practical or efficient steam engine.

The statutes which now regulate the granting of patents in England are those of August 25, 1883, (46 and 47 *Vict. ch.* 57,) and December 24, 1888, (51 and 52 *Vict. ch.* 50.) It is not necessary that a person should be a British subject to apply for a patent. The application must state that the applicant is in possession of an invention of which he claims to be the true and first inventor. The word "inventor" in these statutes covers an introducer. It is declared by the act of 1883 that the word "inventor" means

---

[1] Abstract of address delivered at the Patent Centennial Celebration, Washington, April 8, 1891.

"any manner of new manufacture, the subject of letters-patent and grant of privilege," within section 6 of the act of 21 James I., chapter 3, and includes an alleged invention. There must be either a provisional or a complete specification. If there is only a provisional specification, there must be a complete specification within nine months after the application. There is a limited examination which extends only to an inquiry whether the nature of the invention has been fairly described, and whether the application, specification, and drawings, if any, are in due form, and whether the title sufficiently indicates the subject-matter of the invention. The acceptance of the complete specification is to be advertised, and any person may, within two months thereafter, give notice at the Patent Office that he opposes the grant of the patent on the ground that the applicant obtained the invention from him or from a person of whom he is the legal representative, or on the ground that the invention was patented in England on an application of prior date, or on the ground that the complete specification describes or claims an invention other than that described in the provisional specification, and that such other invention forms the subject of an application made by the opponent in the interval between the making of the two specifications. The patent is to be granted for 14 years, but is to cease if certain fees are not paid within specified times. Disclaimers and amendments of specifications are provided for, but no amendment is allowable which would make the specification, as amended, claim an invention substantially larger than, or substantially different from the invention claimed by the specification as it stood before amendment. At least six months before the time limited for the expiration of the patent, the patentee may apply for an extension, which may be granted on a favorable report from the judicial committee of the Privy Council, for a further term not exceeding 7, or, in exceptional cases, 14 years, and a patent may be vacated by a court on certain specified grounds.

Let us pass now to the patent statutes of the United States.

The Constitution, in article 1, section 8, declares that the Congress shall have power to promote the progress of science and useful arts by securing, for limited times, to inventors the exclusive right to their discoveries.

The first act of Congress on the subject was that of April 10, 1790, entitled "An act to promote the progress of useful arts." This provided for the granting of a patent to the inventor or discoverer of any "useful art, manufacture, engine, machine or device, or any improvement therein, not before known or used." A written specification with drawings, and, if admissable, a model, was required. No examination as to the novelty of the invention was provided for. On an application made to a judge of a District Court within one year after the grant of a patent, if it was obtained surreptitiously or upon false suggestion, or if it should appear that the patentee was not the first or true inventor or discoverer, the judge might repeal the patent.

Further acts in regard to patents were passed in 1793, 1794, 1800 and 1832.

On July 4, 1836, an act was passed reorganizing the patent system and repealing all prior acts. By that act patents were to be granted for fourteen years, with the privilege of an extension by the Commissioner, in a proper case, for seven years more. It was required that the applicant should have discovered or invented a new and useful art, machine, manufacture, or composition of matter, or a new and useful improvement thereon, not known or used by others before his discovery or invention, and not, at the time of the application, in public use or on sale, with his consent or allowance, as the inventor or discoverer. He was required to deliver a written description of his invention or discovery, and of the manner and process of making, constructing, using, and compounding the same, in such full, clear, and exact terms, avoiding unnecessary prolixity, as to enable any person skilled in the art or science to which it appertained, or with which it was most nearly connected, to make, construct, compound, and use the same; and in case of a machine, to explain fully the principle and the several modes in which he had contemplated the application of that principle or character by which it might be distinguished from other inventions; and particularly to specify and point out the part, improvement, or combination, which he claimed as his own invention or discovery. Drawings were provided for, and specimens of ingredients of a composition of matter, and a model of machinery, where admissable. A system of examination was instituted, and the patent was to issue if it should not appear to the Commissioner that the alleged invention or discovery had been invented or discovered by any other person in this country, prior to the alleged invention or discovery by the applicant, or that it had been patented, or described in any printed publication, in this or any foreign country, or had been in public use or on sale with the applicant's consent or allowance, prior to the application, and if the Commissioner should deem it to be sufficiently useful and important. On the refusal of a patent, an appeal was provided for to a board of three examiners. An interference with another pending application, or with an unexpired patent, could be declared, with an appeal to a like board. In case a patent should be inoperative or invalid, by reason of a defective or insufficient description or specification, or by reason of the patentee claiming in the specification as his own invention more than he should have a right to claim as new, if the error arose by inadvertency, accident, or mistake, and without any fraudulent or deceptive intention, the Commissioner, on the surrender of the patent, could cause a new patent to be issued to the inventor for the same invention, for the residue of the period then unexpired for which the original patent was granted, in accordance with the patentee's corrected description and specification. This was called "a reissue," Provision was made for special defences in actions for damages for infringement, and for giving to the plantiff thirty days' notice before the trial, of the defense of prior use; also for a remedy by bill in equity in the case of two interfering patents, or of the refusal to grant a patent on the ground of its interference with a previous unexpired patent. Equity jurisdiction by the Circuit Courts of the United States was created. with the power of granting injunctions against infringement. An extension of a patent for seven years was provided for, on its appearing that the patentee, without neglect or fault on his part, has failed to obtain reasonable remuneration,

The foregoing features of the patent system were substantially re-enacted in the act of July 8, 1870, the provisions of which are embodied in the Revised Statutes; but by statute a patent is now granted for only 17 years, and no provision is made for an extension.

In the administration of the patent laws by the courts of the United States, the proper rights of inventors have been firmly maintained, while the abuses which crept in, in consequence of improper reissues of patents, have been corrected. Patents for important and meritorious inventions have been sustained, notably in the case of Morse's telegraph, which was held valid in the case of *O'Reilly* v. *Morse* (15 *Howard*, 62,) the opinion being delivered by Chief Justice Taney.

Samuel F. B. Morse was a historical painter, and had gone to Europe in 1829 to perfect himself in his art. In October, 1832, on board the packet-ship "Sully," on her passage from Havre, in France, to New York, he conceived the invention which he afterward patented. He persevered in his invention, and by the forepart of the year 1836 he had constructed an instrument which marked down intelligibly telegraphic signs, and demonstrated by actual operation its capacity to accomplish his purpose. Further experiments were made, and in the latter part of September, 1837, a caveat was drawn up and in the following month was filed in the Patent Office. In February, 1838, a new instrument was exhibited by Professor Morse in the Franklin Institute, at Philadelphia, where it operated with success through a circuit of ten miles of wire; and a committee of the Institute made a report of its success. It was then removed to the city of Washington, and publicly exhibited in the hall of the House of Representatives. On the 3d of March, 1843, Congress appropriated $30,000 to test the capacity and usefulness of the telegraph, by constructing a line under the superintendence of Professor Morse, between the cities of Washington and Baltimore, which was done in the year 1844. The United States patent having been granted to him on June 20, 1840, it was reissued in January, 1846, and came before the Supreme Court of the United States at its December term, 1853. It was sustained after a vigorous opposition.

The principle on which the patent laws are based is to give an inventor an exclusive right, for a limited time, in consideration of his fully disclosing his invention, so that it may be made and used by the public after the limited term shall have expired. Under this stimulus there has come into existence the brilliant succession of inventions which have contributed so greatly to the progress of the science and the arts, and to the material welfare of nations and individuals. In this career our own country has played no small part, and it is quite certain that in the future American inventors will do their full share toward illustrating the beneficent operation of the patent laws, and that when, a hundred years hence, there shall be another centennial celebralike the one through which we are now passing. there will have occurred no diminution of the importance and value of American inventions.

AN ITALIAN ELEVATED ELECTRIC RAILWAY.

The highest elevated railroad in the world is about to be built in Naples. It is intended to connect the central part of Naples with the Corso Vittorio Emanuele. It is designed by civil engineer Adolfo Aveno, and the estimated expense will be about $1,000,000. The road will be suspended from towers 100 metres high, in which will be elevators to carry passengers to the station. The road will be operated by electricity, generated by the force of the waterfall of the river Serreno.

MR. H. R. LEYDEN has resigned his position with the United Electric Light and Power Co., of this city, to take charge of the drafting, and estimating with Mr. Dugald C. Jackson, district engineer of the Edison General Electric Co., at Chicago.

THE
ELECTRICAL ENGINEER.
[INCORPORATED.]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.
Telephone: 3860 Cortlandt. Cable Address: LENGINEER.

GEO. M. PHELPS, President. F. R. COLVIN, Treas. and Business Manager.

Edited by
T. COMMERFORD MARTIN AND JOSEPH WETZLER.

New England Editor and Manager, A. C. SHAW, Room 70—620 Atlantic Avenue, Boston, Mass.
Western Manager, W. F. COLLINS, Temple Court, 225 Dearborn Street, Chicago, Ill.
New York Agent, M. C. SULLIVAN, 150 Broadway.

TERMS OF SUBSCRIPTION, POSTAGE PRE-PAID.

United States and Canada,	per annum,	$3.00
Four or more Copies, in Clubs (each)	"	2.50
Great Britain and other Foreign Countries within the Postal Union	"	5.00
Single Copies,		.10

[*Entered as second class matter at the New York, N. Y., Post Office, April 9, 1888.*]

EDITORIAL ANNOUNCEMENTS

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XI. NEW YORK, APRIL 15, 1891. No. 154.

In science, as in religion, we see as through a glass darkly, and we must not attach too much importance to forms of thought, which, like all things human, are subject to limitations and liable to change.—Josiah Parsons Cooke.

THE PATENT CENTENNIAL CELEBRATION.

THE celebration last week in Washington of the granting of the first American patent 100 years ago, and of the beginning of the second century of the American patent system, proved of much interest. To a certain extent it has seemed as though the celebration lacked spontaneity on the part of those who joined in it and suffered for the lack of some definite purpose, but, on the whole, such an event must be productive of good, and as our report of the proceedings and papers shows not a few wise and sensible things were said, while the resolve to be practical was manifested in the organization of the national association of patentees.

The patent system of this country, based on a mere score of words in the Constitution, has certainly been worthy of the praise bestowed upon it, and while there are some things that might be bettered, it is to be hoped that in the main the system will stand as it is another hundred years. The trouble in a country like this, where we start out with conditions and institutions about as nearly right as they ought to be, is to keep in check the hankering after change and novelty that is a big part of human nature, and to which, in fact, the American pre-eminence in invention is largely due. However, there is no very burning desire in any quarter to make radical changes in the system, and we trust, therefore, that it will be allowed to go on doing its great work. But in order that this work may be most successfully performed, a number of minor improvements are unquestionably needed. A new Patent Office building is wanted, or else the old building must be devoted to its original and legitimate purpose. The force in the Patent Office should be better paid, and the men there should be given inducements to stay after they have become valuable. The arrears of work should be brought up. At this minute over 7,000 applications await attention. In some departments of electricity, the applications are two and three months behind, and yet in these times of active electrical development, a month counts like a century.

Now it cannot be said that such reforms will cost the nation anything. The excess last year of Patent Office income over expenditure was $200,000, and the total surplus is about $4,000,000. Now this money should be spent in such ways as here suggested for the benefit of the inventor, or else the tax on invention in the shape of fees proved to be unnecessarily high should be mitigated. So far from costing the country anything, any liberal and just measure of this kind will return tenfold on the outlay required for making it.

PROF. THOMSON'S NEW ALTERNATOR.

THE discussion which has been carried on in our columns recently on the phenomena connected with alternating currents of high frequency, has naturally drawn attention to the machines by which these high frequencies are produced. We have already described the machine designed by Mr. Tesla for that purpose, and have drawn attention to the general design adopted by Prof. Elihu Thomson. In this issue we are enabled to present the Thomson machine as it has been actually constructed, with some of the detailed information regarding its performance. The results there given show the machine to be one of very efficient design, and though only tested over a small range of loads, the indications are that even at its maximum capacity the machine will prove of high efficiency. The mechanical construction has also a number of advantages, not the least among which is the fact that all wire employed on the machine is stationary, the multipolar magnet alone being kept in motion.

THE TELEPHONIC DISASTERS AT ALBANY.

WE presume that the entire electrical fraternity is familiar with the terrible and frequent disasters that the Albany Exchange of the Hudson River Telephone Co. has recently met with, and that every one has felt the greatest sympathy with Mr. A. B. Uline, the manager, in his troubles. It is more than serious to have an exchange service practically wiped out four times by storm and fire in four months, and the occurrences have elicited no end of discussion, as well as no little alarm, among telephone subscribers. Very naturally the telephone people hold the electric railway trolley wire responsible for most of their trouble in this matter, and we understand that they now anticipate frequent repetitions so long as the city permits the railway to use its trolley wires without guard wires overhead.

This brings up a very important question, as the benefits of "guard wires" are not indisputable. We have therefore asked Mr. W. H. Cull of Albany, to give us his views on this subject, as one peculiarly qualified to express an opinion of value. Mr. Cull, while superintendent and electrician of the Albany railway to-day, which he has made one of the "show roads" of the new industry, was also for seven years superintendent and electrician of the Hudson River Telephone Co. Hence he is better informed, perhaps, than any other man in the country as to the difficulties and objections on each side. In reply to our inquiries, Mr. Cull says :—

> "The expense of putting up these guard wires ought to be a matter of very little importance to a railway company, for a perfect guard wire would prove as great a blessing to them as to telephone and telegraph companies. The present imperfect guard, or protecting wire, I consider of very little avail for protecting either foreign wires, or the trolley wire ; they are so frequently 'alive,' that it almost makes a farce of the purpose they are intended for. It is said, a conductor on one of the electric cars in Boston noticed that the trolley wheel was arcing very badly ; upon examination he discovered that the car had been running some yards with the trolley wheel on the guard wire. An inspection of the line was made and it was found that a 'dead' telegraph line had fallen across the guard wire, and one of the span or suspension wires, which was imperfectly insulated from the trolley wire ; enough electricity escaped through this contact to propel a car ; this is one of the many ways that guard wires become 'alive,' and in many cases the cause of much damage."

Here is evidently a point well worth consideration. A precaution, which like some of the alleged "lightning protectors" is simply an added danger, cannot be too soon exposed. Mr. Cull adds, however : "I do not wish to be understood as being opposed to guard wires, on the contrary, I say, by all means put them up, and keep them as "dead" as if they were "buried," if it is possible to do so. The writer is familiar enough with the Telephone Exchange system to know that a wire carrying a high potential current, coming in contact with a telephone wire, is, to say the least, a decided nuisance, and the cause of much unparliamentary language from telephone managers. Quite frequently these crosses do not make themselves manifest until considerable damage has been done. It is these "sneak" currents that are most to be dreaded ; then too, many times, linemen cannot find where these crosses have occurred, as was the case in Albany last Monday." The telephone people charged that a telephone wire, ending about two miles out of the city, was crossed with the Albany Railway's trolley wire, but a thorough search and examination by both the telephone and railway company's linemen failed to elicit any evidence whatever of this wire having been crossed with the trolley wire.

Of course, with the placing of telephone wires underground, the liability to these disasters becomes much less. With the adoption of arresters that will arrest, the danger will also be minimized. But a large majority of the wires will remain overhead, and the telephone people do not seem to have been very well satisfied with the protectors they have tried. Under these circumstances, and as to meeting the situation, Mr. Cull says :—

> "It is hard to suggest a remedy to prevent the damage caused by reason of these frequent crosses. My own idea would be, to have two, or three linemen or inspectors, whose duties it would be to report to the manager of an exchange on all stormy days or nights, and to be stationed at the distributing board, cupola and switchboard, to keep a constant lookout for heavy current crosses ; and another man whose duties it would be to daily examine the fuse board and see that every wire running in the office had a suitable fuse connected therein. In fact, establish a sort of "fire patrol." A two or four volt, one-sixth ampere incandescent lamp introduced in each circuit at the distributing board would disclose the presence of any current sufficiently strong to damage the switchboard drop. In most cases they would open the line. This, however, would be quite expensive."

The overhead system is here to stay, having, not less than the telephone, proved its right to existence as an enormous and incalculable boon to the public. But it must be apparent that in view of the conditions dealt with above, the electric railway conduit becomes also an improvement at once highly necessary and important and the storage system remains as inviting a solution as ever of the problem.

THE BELL TELEPHONE COMPANY AND THE MICROPHONE INTERFERENCE.

The letter of Mr. W. C. Barney, on the Commercial Future of the Telephone, printed elsewhere in this issue, puts in a clear light an important feature of the patent situation, one which has occasionally been touched upon by the daily press, notably by the *N. Y. Times*, and which was brought into prominence during the investigation of the telephone companies by the New York legislature several years ago. There seems little doubt that in the existing state of the art a broad microphone patent would be the one strongest hold for the American Bell Telephone Company after the expiration of the Bell patent.

Although that company may be within its legal right in refraining from bringing the Berliner-Edison interference to a determination, and thus deferring indefinitely the issue of a microphone patent good for seventeen years ; we believe that this policy—and such appears to be its policy—involves a substantial grievance and an injustice to the public, and that its probable result—adding ten or twelve years to the effectual life of a patent—is abhorrent to the spirit and intention of our patent law.

We have regarded the attacks in the public press upon the general policy of the American Bell Telephone Company as, for the most part, ill-founded, immoderate and unfair, prompted by little knowledge and less sincerity ; but the indefinite suspension of the microphone case, unless the Bell Company can show satisfactory reason for it other than its obvious pecuniary interest will do much to augment and justify public dissatisfaction and complaint. The question is much broader than its bearing upon the single case referred to.

A Useful Index.

With this issue of The Electrical Engineer will be found a very thorough and complete index to the contents of Vol. X. There are various features that will recommend it for use, especially the system of explanatory notation and of elaborate cross reference, by which the nature of the article and its contents can be determined at once. The supplementary index of authors will also be found extremely useful, as one often remembers an article more by the writer and what he says than by the mere title.

THE HIGHEST ECONOMY IN THE USE OF INCANDESCENT LAMPS.

BY

H Ward Leonard

IN operating incandescent lamps of any particular make, their average life will depend upon the incandescence at which they are operated. The higher the incandescence of the carbon filament, the greater the amount of light which will be produced by the expenditure of a certain amount of energy, and the less the average life. *Lamps can be made by any manufacturer which shall have practically any desired average life, if the efficiency be not fixed.* As we decrease the power necessary, that is, increase the efficiency, we effect a saving in the first investment and in the cost of power required to operate the lamps, but simultaneously we decrease the average life of the lamps, and hence increase the cost in operating due to lamp renewals.

It will, therefore, be evident that whenever the cost of power and the cost of incandescent lamps for renewals is fixed, there will be a certain definite efficiency and corresponding life, which for any particular make of lamp will represent the condition of highest economy in the use of the lamps. The consumer of incandescent lamps has forcibly brought to his attention the cost of the lamps he uses for renewals, but is usually unable to determine definitely the amount and value of the power required to operate the lamps. Consequently, he is frequently led to believe that the *cheapest* lamp for him to use is necessarily that which gives the *longest life.* Unless the power required is the same for the different lamps, this is not true, and frequently consumers are operating at very poor economy, and yet believe they are obtaining very good results, merely because their lamp breakage is small.

Let us examine this subject briefly. The measurement of light is rated in "candle power," and the efficiency of production of the light is rated in "watts per candle." The number of watts required by any lamp is the product of the volts and amperes used by the lamp. Thus a 100 volt lamp using ½ an ampere absorbs 50 watts, and if the lamp be a 16 c. p. lamp, the "watts per candle," which is the measure of its efficiency, would be $\frac{50}{16} = 3.1$ watts per candle. Similarly, a lamp of 24 c. p. taking 110 volts and .676 ampere absorbs 75 watts, and has an efficiency as before, of $\frac{75}{24} = 3.1$ watts per candle. These two lamps, operated as indicated above, will have the same average life, because the incandescence of the carbon, and therefore the efficiency, is the same in the two instances. Let us suppose this average life to be 600 hours with the efficiency mentioned, namely, 3.1 watts per candle.

Now, suppose we take the lamp designed to be operated at 3.1 watts per candle, giving 24 c. p. at 110 volts, and instead of subjecting it to 110 volts, reduce the pressure to 104 volts. The reduction of pressure will cause a reduction in the current through the lamp from .676 ampere to .623 ampere; consequently, the watts absorbed by the filament will be 104 x .623 = 65 watts. The candle-power will be found to be 16 instead of 24 as formerly. The efficiency will be $\frac{65}{16} = 4.+$ watts per candle. The *average life* at this efficiency will be not less than 1,500 *hours.* Yet it *does not follow* that the *most economical results* will be obtained by operating the lamps at *such an efficiency and life,* although at first such might be thought to be the case.

In order to investigate this question, it becomes necessary to determine the cost of power under different conditions. Perhaps the best authority on this subject is Charles E. Emery, Ph. D., who has thoroughly investigated and reported upon this question. The following values are taken from his report:

The cost of producing 1 h. p. for 10 hours per day for 309 days in the year, by means of a first-class engine using 27 pounds of feed water per indicated horse-power per hour, is $52.15, where anthracite coal is $4.17 per ton, and where an engineer's wages are $2.00 per day. Of this $52.15, $24.06 is the cost of the coal, and $28.09 is that due to expenses outside of coal, such as wages, repairs, oil, waste, insurance, taxes, &c. That is, it costs $52.15 to produce 309 x 10 = 3,090 h. p. hours, hence 1 h. p. hour costs $\frac{52.15}{3,090} = 1.7$ cents.

The cost of the power for operating a 16 c. p. incandescent lamp will, of course, vary with the number operated per horse-power. When the lamps have an efficiency of 3.1 watts per candle, twelve 16 c. p. lamps are operated for each horse-power in the driving belt of the dynamo.

When the lamps have an efficiency of 3.6 watts per candle, 10-sixteen candle power lamps are operated per horse power; with lamps of 4 watts per candle, 9-sixteen candle power lamps are similarly operated per horse power, and with 2.77 watts per candle 18.4-sixteen candle power lamps. Consequently the cost of the power will be as shown in Table I. for operating one 16 candle power lamp for one hour:

TABLE I.

	For lamps of 2.77 watts per candle, *i. e.*, 18.4 lamps to H. P.	For lamps of 3.1 watts per candle, *i. e.*, 12 to H. P.	For lamps of 3.6 watts per candle, *i. e.*, 10 to H. P.	For lamps of 4 watts per candle, *i. e.*, 9 to H. P.
Cost of power per 16 c. p. lamp hour, with power at 1.7 cents per horse power hour.....	0.129 cts.	0.14 cts.	0.17 cts.	0.19 cts.

If the average life of the lamps of 3.1 watts be 600 hours, that of the 3.6 watts lamp will be about 900 hours, that of the 4 watts lamp 1,500 hours, and that of the 2.77 watts lamp 300 hours.

Let us assume that the initial cost of a 16 candle power lamp is 44 cents, then the cost of renewals per lamp hour would be as shown in Table II.

TABLE II.

	For lamps of 2.77 watts per candle, *i. e.*, 18.4 16 c. p. lamps to H. P. and 300 hours average life.	For lamps of 3.1 watts per candle, *i. e.*, 12 to H. P. and 600 hour life.	For lamps of 3.6 watts per candle, *i. e.*, 10 to H. P. and 900 hour life.	For lamps of 4 watts per candle, *i. e.*, 9 to H. P. and 1,500 hour life.
Cost of lamp renewals per 16 c. p. lamp hour, with lamps at 44 cents each.	0.146 cts.	0.073 cts.	0.049 cts.	0.029 cts.

Hence, the combined cost of both power and lamp renewals would be as shown in Table III.

TABLE III.

	For 16 c. p. lamps of 2.77 watts per candle and 300 hours average life.	For 16 c. p. lamps of 3.1 watts per candle and 600 hours average life.	For 16 c. p. lamps of 3.6 watts per candle and 900 hours average life.	For 16 c. p. lamps of 4 watts per candle and 1,500 hours average life.
Power..................	.129 cts.	.140 cts.	.170 cts.	.190 cts.
Lamp Renewals	.146 cts.	.073 cts.	.049 cts.	.029 cts.
Total cost per 16 c. p. lamp hour when power costs 1.7 cents per horse power hour and incandescent lamps cost 44 cents each..............	0.275 cts.	0.218 cts.	0.219 cts.	0.219 cts.

Thus, under the conditions given, the *most economical lamps* to use will be those of 3.1 *watts* per candle and 600 *hours* average life.

Now, let us suppose that the cost of power varies, as it will in different locations and under different conditions. It will be noted that of the $52.15 per year for the production of one horse power, $28.09, or 54 per cent., is independent of the cost of fuel. Let us suppose that the cost of fuel is nothing, and that the only expense in the production of power are those due to labor, repairs, insurance, taxes, etc., Table IV.

TABLE IV.

	For 16 c. p. lamps of 2.77 watts per candle and 300 hours average life.	For 16 c. p. lamps of 3.1 watts per candle and 600 hours average life.	For 16 c. p. lamps of 3.6 watts per candle and 900 hours average life.	For 16 c. p. lamps of 4 watts per candle and 1,500 hours average life.
Power...............	0.0684 c.	0.0742 c.	0.0901 c.	0.1007 c.
Lamp Renewals.......	0.1460 c.	0.0730 c.	0.0490 c.	0.0290 c.
Total cost per 16 c. p. lamp hour when fuel costs nothing and incandescent lamps cost 44 cents each.	0.2144 cts.	0.1472 cts.	0.1391 cts.	0.1297 cts.

It will be seen that the four watt lamp of 1,500 hours average life becomes the most economical to operate under such conditions.

Now, suppose the price of anthracite coal, or its equivalent, to be $2.00 per ton. We then have the following relations, Table V.

TABLE V.

	For 16 c. p. lamps of 2.77 watts per candle and 300 hours average life.	For 16 c. p. lamps of 3.1 watts per candle and 600 hours average life.	For 16 c. p. lamps of 3.6 watts per candle and average 900 hours life.	For 16 c. p. lamps of 4 watts per candle and average 1,500 hours life.
Power..................	0.0991 c.	0.108 cts.	0.089 cts.	0.146 cts.
Lamp Renewals.......	0.146 cts.	0.073 cts.	0.649 cts.	0.029 cts.
Total cost per 16 c. p. lamp hour where anthracite coal, or its equivalent, costs $2 per ton, and 16 c. p. lamps cost 44 cents each...	0.245 cts.	0.181 cts.	0.178 cts.	0.175 cts.

From the above figures it will be seen that the four watt lamp is the cheapest to operate under the conditions given, but the advantage is so trifling that in practice the 3.1 watt lamp would be the best to use, since the lamps fall off in candle power somewhat in long use, and with lamps having an average life of 600 hours, the average condition of the total number of lamps on a plant would be that due to 300 hours of burning, whereas the average condition of lamps having an average life of 1,500 hours would be that due to 750 hours' use, and it is evident that it will be preferable to have lamps which have averaged 300 hours of use, rather than lamps which have averaged 750 hours of use.

It will be seen by the figures given that the *life alone is a poor measure of the economy of an incandescent lamp*, and that in order that a four watt lamp should equal in quality a 3.1 watt lamp, its life should be 2½ times as long, and that its average candle power in burning its 1,500 hours should equal the average candle power of the 3.1 watts lamp in burning its 600 hours.

In all instances quoted thus far we have assumed a cost of power based upon its production for ten hours per day under extremely favorable conditions. In the case of incandescent lighting plants, the load changes widely, and the maximum load is on for only two or three hours. The production of power is much more expensive under such conditions than when the load is constant. Statistics from a very large number of central station incandescent lighting plants, charging an average rate of 1 cent per 16 candle lamp hour, show that the total cost of power for operating a 16 c. p. 3.1 watt lamp is 0.4 cent per hour. *The relative economy in the use of lamps of different efficiencies under average conditions of central station practice is, therefore, shown by the following Table* VI:

TABLE VI.

	For 16 c. p. lamps of 2.77 watts per candle and 300 hours average life.	For 16 c. p. lamps of 3.1 watts per candle and 600 hours average life.	For 16 c. p. lamps of 3.6 watts per candle and 900 hours average life.	For 16 c. p. lamps of 4 watts per candle and 1,500 hours average life.
Power...................	0.357 cts.	0.400 cts.	0.464 cts.	0.516 cts.
Lamp Renewals.......	0.146 cts.	0.073 cts.	0.049 cts.	0.029 cts.
Total cost per 16 candle lamp hour when the power to run a 16 c. p. 3.1 watt lamp costs 0.4 cents per hour, and lamps cost 44 cents each...................	0.503 cts.	0.473 cts.	0.513 cts.	0.545 cts.

It will be noticed that the operating expenses are 8 *per cent. less in the case of a plant using* 3.1 *watt* 600 *hour lamps than in the case of a plant using* 3.6 *watt* 900 *hour lamps. This is equivalent to an increase in the net profits of* 12 *per cent. in the case of an incandescent electric lighting company* whose expenses are 60 per cent. of the total receipts, which is an average relation between the expenses and receipts in properly operated stations.

Attention is called to the fact that if the life of the incandescent lamp be increased, or the price of the lamp be reduced, the importance of using the high efficiency lamp rather than the low efficiency lamp becomes even more marked than in the present instance. Thus, if the average life of a 16 c. p. lamp of 3.1 watts be 1,200 hours, and the cost of the lamp be 40 cents, it will be found that higher economy will result by operating the lamp at 2.77 watts per candle which will reduce the life to 600 hours. This is shown by the following table:

	For 16 c. p. lamp of 2.77 watts per candle and 600 hours average life.	For 16 c. p. lamp of 3.1 watts per candle and 1,200 hours life.
Power.......................................	0.357 cts.	0.400 cts.
Lamp Renewals...........	0.066 cts.	0.033 cts.
Total cost per 16 c. p. lamp hour when power for 3.1 watt lamp costs 0.4 cent per hour, and lamps cost 40 cents each...	0.423 cts.	0.433 cts.

In all systems having a fairly good regulation and distribution of pressure, and where coal costs from $2 upward for the equivalent of one ton of anthracite coal, the 3.1 watt lamp is the most economical.

In alternating systems as ordinarily installed, the variation of pressure is often too great to use the 3.1 watt lamp economically, and the 3.6 watt lamp should be used. Also in cases when the cost of power is extremely low, the 3.6 watt lamp should be used. It will not be found economical to operate the best makes of lamps at more than 3.6 watts per candle under any conditions met with in practice.

The majority of 16 *c. p. incandescent lamps on the market today require from* 57 *to* 65 *watts*, that is, to have an efficiency of from 3.6 to 4 watts; and attention is called to the fact that *in order to compare in quality with a lamp of* 50 *watts* with a guaranteed average life of 600 *hours* there should be a guarantee of 900 *hours* average life for the 57 *watt lamps*, and of 1,500 *hours* average life for the 65 *watt lamps*, and that *even then the consumer will not be operating at the highest economy* as shown above. Furthermore, it must be borne in mind that *by the use of* 3.1 *watt lamps*, the *capacity* of a plant already using 3.6 watt lamps, will be *increased* 16 *per cent.*, and in the case of a plant using 4 watt lamps, the *capacity* will be *increased* 30 *per cent.*

To express this another way, it may be said that a *consumer* having a plant *using* lamps of 3.1 *watts*, and *changing* to lamps of 4 *watts*, not only suffers the disadvantage due to the fact that he is *not operating* at the *highest economy*, but he also immediately *increases* his investment, interest, depreciation, &c., per unit of light obtained, to the extent of 30 *per cent.* and subjects his *dynamo* to an *overload* of 30 *per cent.*, with consequent greatly increased trouble and expense *due entirely to the use of the low economy lamps*, but frequently attributed to a defect in the dynamo as it is there that the overload manifests itself.

MR. E. A. SMITH has been appointed manager of the Meriden, Conn., telephone office.

NOTE ON THE RELATIVE DEGREE OF DISTURBANCE CAUSED BY ELECTROSTATIC AND ELECTROMAGNETIC INDUCTION BETWEEN CERTAIN SIMPLE ARRANGEMENTS OF TELEPHONE CIRCUITS.[1]

BY A. E. KENNELLY.

REFERRING to Fig. 2 of Mr. Carty's paper,[2] let L_1 be a primary line, L_2 and L_3 the lines of a secondary circuit. Suppose also, to simplify the conditions, that L_3 is so far remote from L_1 and L_2 by comparison with the half inch of distance separating these latter, that all inductive influence on or from L_3 may be omitted from consideration. The most convenient way of dealing with L_3, is to replace it by the ground, and we have then only to consider the two circuits L_1 and L_2 each taken as negligibly small for the case under discussion.

By considering first the amount of disturbance that would be statically set up in L_2 if electromagnetic action did not exist; and second the magnetic disturbance on the hypothesis that no static induction took place, it is possible to form a comparative estimate of the relative proportions of these disturbances, when, as in practice, both influences act together. The result will not be accurate, because the influence of each not only combines with, but also to a certain extent modifies, the action of the other; but the discrepancy due to so elementary a treatment will not in all probability invalidate the results as a first approximation.

Let k be the mutual electrostatic capacity of L_1 and L_2 per centimetre length of each, in A. E. M. U.
Let μ be the mutual electromagnetic capacity, or mutual inductance of L_1 and L_2 per cm. of each in A. E. M. U.
Let e be the primary circuit E. M. F., which is periodic in value.
Let n be the number of periods completed by e per second.
Let ω_1 be the impedance in the circuit of L_1 in A. E. M. U.
Let ω_2 be the impedance in the circuit of L_2 in A. E. M. U.
Let γ_s be the current in each of the two end telephones of the secondary circuit owing to electrostatic induction when electromagnetic induction is supposed to be absent.
Let γ_m be the current in each of three telephones in the secondary circuit (one of the centre of L_2 and the others at its ends), when electromagnetic action is supposed to exist between the circuits to the exclusion of static induction.
Let r be the radius of each wire (copper), in cms.
Let the wires be parallel and the distance between their axes be d cms. in the horizontal plane elevated h cms. above the ground.

Since γ_s and γ_m are periodic currents of the same frequency, they will produce equally loud sounds in the telephones when of equal numerical value, and the ratio of static to magnetic disturbance in the two cases will be

$$\frac{\gamma_s}{\gamma_m} = \frac{k}{\mu}\,\frac{\omega_1\,\omega_2}{2}.$$

Provided then, that the impedance of the primary circuit at the receiving end is always large, the ratio of static to magnetic disturbance will be approximately expressed by this equation. In order to apply it to the case of Fig. 2, we have to determine from the geometrical relations of the wires their mutual capacities k and μ.

The value of k in A. E. S. U. has been given by Mr. Oliver Heaviside in the *Journal* of the Society of Telegraph Engineers (London) for April, 1881 (with a misprint in the formula here avoided)

$$k = \frac{\frac{1}{2}\log_e \dfrac{\sqrt{d^2+4\,h^2}}{d}}{\left\{\log_e \dfrac{2\,h}{r}\right\}^2 - \left\{\log_e \dfrac{\sqrt{d^2+4\,h^2}}{d}\right\}^2}$$

Substituting for d 1.25 (cms. or half an inch.)
for h 1000 (cms. or about 33 feet.)
for r 0.1 (cms. or 0.04″ about representing No. 12 B. & S. gauge.)

$k = 0.0714$ A. E. S. U. $= 7.94 \times 10^{-23}$ A. E. M. U. or 0.0128 microfarads per mile.

The value for μ can also be found from another formula first published by Mr. Heaviside in the *Journal* of the above mentioned society for May, 1878, namely:

$$\mu = \log_e \frac{d^2+4\,h^2}{d^2}$$

from which $\mu = 14.75$ A. E. M. U. or 2.87 millihenrys per mile.

Thus for equality between γ_s and γ_m we must have with these values of k and μ

$$\omega_1\,\omega_2 = 3.717 \times 10^{23} \text{ A. E. M. U.}$$

Three telephones of 75 ω and 90 h each would, to a frequency of $n = 435$ corresponding to the note a^1, offer an impedance of $\omega_2 = 7.72 \times 10^{11}$ or 772 ohms, the impedance of the three telephones to this frequency being more than three times their resistance.

For $\gamma_s/\gamma_m = 1$, ω_1 must now be $3.717 \times 10^{23}/7.72 \times 10^{11}$ or 4.816×10^{11} or 481.6 ohms, in round numbers 500, while with the primary circuit of Fig. 2 having a transmitter of 165 ω and 730 h with a call-bell at the distant end of 550 ω and 2.7 H, the total resistance would be 715 ω, the total inductance 3.43 H, and the impedance to the same frequency of $n = 435$ would be $9.40 \times 10^{11} = 9400$ ω or about thirteen times greater than the total resistance. The impedance ω_1 is thus nearly twenty times greater than that needed by the formula for equality between γ_s and γ_m and roughly the static disturbance in Fig. 2 may be estimated as twenty times greater than the magnetic.

INTERNATIONAL PROTECTION OF INDUSTRIAL PROPERTY.[1]

BY COL. F. A. SEELY.

THE difficulty in securing international protection for inventions exists by reason of systems of law in many countries, under which an alien inventor is debarred from protection by reason of having first complied with the law in his own country. Much thought has been expended upon the removal of this difficulty, but the true and universal solution has been missed in Europe by the failure to take cognizance of radical differences in patent laws. Since in most countries the publication of a description of an invention constitutes a bar to the grant of a patent or vitiates one if subsequently obtained, it would seem that the difficulty would vanish if the nations of the world were to agree that such publication, when official, and in connection with the grant of a patent in any country, should not affect the inventor's right in any other.

The International Convention of Paris in 1883, while wisely planned in many respects, fails of its purpose when considered from an American aspect, because it failed to take note of special features of American patent law.

It established what is called a period of priority, running from the deposit of the application for patent, during which the inventor might file his application in the other countries accepting the convention, without having his rights affected by anything occuring in the interval, including publication or the grant of the patent to a third party. This works very well in countries where there is no examination into novelty, and where the publication follows the deposit after only a short interval. It does not work in the United States, because in most cases the whole period of priority expires before the grant of the patent in this country, and the inventor rarely is willing to take out patents abroad till he has secured them at home. If the period of priority had at first been adjusted so as to run from the publication rather than from the deposit, it might have been satisfactory to the other countries, and at the same time advantageous to the American inventor. This was the proposition of the United States that was voted down in the Madrid Conference in 1890.

The scheme proposed by the Pan-American Congress took no note whatever of the United States patent law. It was based on the laws of the majority of the South American States, which differ widely from ours, and the principal features of the scheme are wholly incompatable with our system.

Absolute reciprocity exists between this country and Canada, and the laws of Venezuela and Hawaii resembles ours in so many particulars that it may be said to exist with them also. By an amendment recently proposed to the German Law, to go into effect October 1st, that Empire practically accepts the American proposition which was refused at Madrid.

Our law fully recognizes the international principle; it is more liberal than any proposed terms of reciprocity. In fact, its very liberality constitutes a bar to agreements with other nations, because we have no concessions to make in return for those we demand. The wisest and most hopeful course for us appears to be, to take note of the concessions mutually made by other nations for the benefit of their own people, and secure to our own people the benefit of these concessions, which by our liberal legislation we are prepared to do.

"IN THE LEAD."

A well-known electrical engineer in Boston, writing of THE ELECTRICAL ENGINEER says: "Its able character has placed it in the lead of all other electrical papers published in this country."

MILEAGE OF ELECTRIC WIRES.

It has recently been estimated that there are 1,500,000 miles of operative electric circuit in this country, or enough to go 60 times around the earth at the equator.

[1] A paper read at the Patent Centennial Celebration, April 8, 9, 10, 1891.

INSTITUTE DISCUSSION ON TELEPHONIC INDUCTIVE DISTURBANCES.

THE discussion of Mr. J. J. Carty's paper on "Inductive Disturbances in Telephone Circuits," was opened by **MR. A. E. KENNELLY**, who corroborated the results obtained by Mr. Carty, by calculations given in a *Note* on p. 450, this issue.

MR. CARTY :—I would like to describe a few experiments to prove that when a man is talking on one wire and his speech is heard by induction on a parallel wire, that that speech finds its way between the two wires by virtue of electrostatic induction, and that electro magnetic induction is entirely negligible.

I will first show what I consider the most favorable condition for creating electro-magnetic induction between two telephone wires. T, Fig. 1, represents the coil of a long distance transmitter sending the most powerful telephone current that it is now possible to generate. L^1 represents the wire connected to earth. It may be, we will say, 200 feet long. Parallel to it and an eighth of an inch away, we will place another telephone circuit. These wires may have an insulation of 10,000 megohms and the resistance might be considered as one ohm. Now a current resulting from a given note in the transmitter through the wire (L^1) produces a series of changes in the magnetic field surrounding it, and that action is roughly explained by assuming that the current starting in L^1 induces a current in L^2 in the opposite direction, and that the induced current will flow through both telephones *a* and *b*. Under those conditions absolutely no sound is heard in the telephones *a* or *b*.

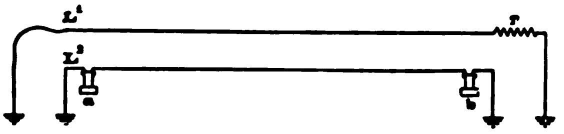

FIG. 1.

Now, I will describe another experiment which I made with those same wires. We will open the wire L^1 (Fig. 2,) at the far end. Then, when the transmitter is operated, noise is immediately heard at the telephones *a* and *b*, located at the ends of the secondary wire, and if a telephone, *c*, be located at the exact centre of impedance it will be found to be silent. When the wire L^1 is opened at the far end we have the maximum electro-static and the minimum electro-magnetic action ; when it is closed we have the maximum electro-magnetic action and the minimum electro-static action. The reason that the electro-static action is slight in Fig. 1 can be seen from Fig. 3. Assuming that *m n* represents the height of potential of the transmitter, the resistance of the circuit is mostly in the transmitter and the fall of potential therein is very sudden. At any point along the wire L^1 the potential would be practically zero, as shown by the dotted line *o p*.

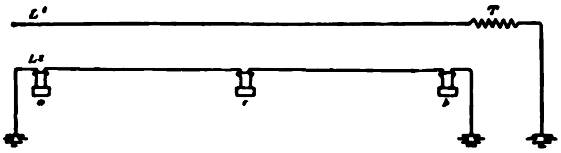

FIG. 2.

I wish to show another experiment in proof of the fact, or what I think is a fact, that electro-magnetic induction is negligible when we consider the action that goes on between two telephone circuits. I expressly limit the statement to the action between telephone circuits, and I am not discussing disturbances in general, but merely inductive cross-talk. We will assume that the circuit is completed by a return wire of no resistance, Fig. 4, or of very low resistance, entirely outside of the field of disturbance, so as to eliminate all questions of leakage through the earth. We will say that L^1 is grounded on a gas pipe. We then have the disturbing wire as before, and when the transmitter is operated loud tones are heard at the end telephones, *a* and *b*. If this were entirely due to the creation of an electro-magnetic field around the disturbing wire, the effect on the secondary wire would be increased by short-circuiting one of the telephones by the key *k*. Now, it is found that when this is done, instead of increasing the sound in the other telephone, it absolutely removes it. The case just described is another condition where you should get an increase of electro-magnetic action, if the disturbance is due to the magnetic field, but the noise, instead of increasing, disappears entirely. You will see how beautifully the thing may be explained by assuming that the disturbance is due to direct electro-static action. In this case we will say that the wire L^1, at a given instant, has a plus charge upon it which induces a minus charge on L^2. Now, when the inducing charge is removed the induced charge divides and flows away at both ends. But as there is a great deal of resistance in telephone *b*, and practically no resistance in key *k*, the charge and discharge of L^2 takes place up and down through the key end and none of it goes through the telephone *b*.

MR. GEORGE B. PRESCOTT, JR., inquired with reference to Fig. 1, whether Mr. Carty had tried the experiment of interrupting a battery current in the inducing circuit by means of an ordinary telegraph key.

MR. CARTY replied that he had employed a vibrator with a powerful current and had used the same secondary wire, and a telephone in the centre, and then found a noise in all three telephones, just exactly what one should expect in dealing with electro-magnetic induction.

MR. CARTY wanted it distinctly understood that his experiments referred only to the disturbance which is produced upon one telephone circuit by induction from another, and that in his experiments he had used the human voice for a disturbing source, and covered the entire range of telephonic currents.

MR. WM. M. MINER inquired if Mr. Carty obtained the same result when the wire that he used, L^1, was about three or four times the length of the secondary, and the secondary, say, a mile in length. He asked this question because in the city of Chester, Pa., and about a mile from the exchange, he had heard, distinctly, the superintendent at Wilmington, Del., about three miles away, talking with the operator at the Chester exchange ; the wires running parallel and both wires grounded.

MR. CARTY had never tried that experiment. He added that all of his experiments had been reproduced, using condensers, and the results from condensers were exactly those got from straight wires.

MR. CARTY :—I wish to point out that there must be some mistake in the reference given by Mr. Lockwood in his note. He says: "Mr. Culley presented a paper once upon this subject before the Society of Telegraph Engineers ; which paper, together with a most instructive discussion, is published in the journal of that society, and Mr. Preece and myself from time to time have also repeatedly referred to it." Mr. Culley has not read a paper of any kind before the Society of Telegraph Engineers or Electrical Engineers since 1875. That was before the invention of the telephone. Mr. Culley's paper of 1875 dealt with the induction of telegraph wires. I put in a foot-note referring to Mr. Culley's paper in my Electric Club paper. I think that that must be what Mr. Lockwood means. I am very familiar with Mr. Lockwood's writings, but I have never seen anything about that in print. If any one else present has, I think it had better be put on record, as the literature of the subject is meagre at best.

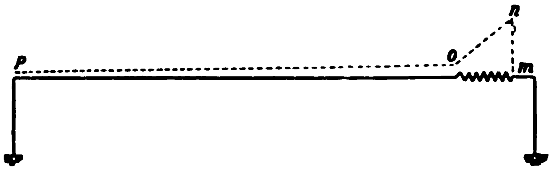

FIG. 3.

MR. H. FRANKLIN WATTS considered that electro-magnetic induction, pure and simple, was produced by magnetic whirls surrounding the disturbing wire. That being the case, was a wire open at one end capable of producing these whirls? If such a wire was *not* capable of producing whirls, then, in the cases to which Mr. Carty referred in which the wire is open, it was evident that it was due to something else besides electro-magnetic induction.

MR. CARTY thought it must be admitted that in the act of charging the wire a current flows, and even although the end be open, that current produces a magnetic field, and all of the effects, while it lasts, that would be produced by a current of the same character flowing in a closed metallic circuit.

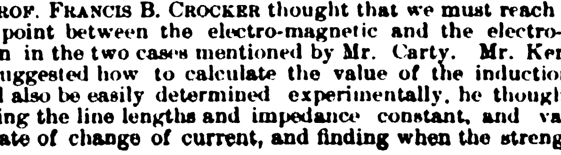

FIG. 4.

PROF. FRANCIS B. CROCKER thought that we must reach a balance point between the electro-magnetic and the electro-static action in the two cases mentioned by Mr. Carty. Mr. Kennelly has suggested how to calculate the value of the induction. It could also be easily determined experimentally, he thought, by keeping the line lengths and impedance constant, and varying the rate of change of current, and finding when the strength of the current or rather the rate of its change, reaches a certain value, at which the electro-magnetic effect is equal to the electrostatic effect. Evidently there must be a point somewhere between the two cases at which a sufficiently low impedance, or a sufficiently great electro-magnetic effect would give audible electro-magnetic inductive disturbances.

In reply to a question by MR. FRANCIS R. UPTON, MR. CARTY stated that 500 feet was the length of most of the lines used; but all of his practical experience confirmed the experiments on these lines, and the system employed to do away with disturbances is effective for both electro-magnetic and electro-static induction.

REGULATION OF CONSTANT CURRENT GENERATORS.[1]

BY ALEX. DOW.

ELECTRICAL power, expressed in watts, is a product of two factors, the electromotive force, and the volume of the current carrying the power. A change in the total power of the current may be expressed by a change of either factor, or of both. In distributions of electric energy it is usual to provide for adjusting the production to the requirements of the work by varying only one factor; the other being maintained constant from minimum to maximum production. Thus we have two commonly recognized methods of distribution, at constant electromotive force, and with constant current. There are cases in practice where both factors may vary; for instance, when a series wound dynamo operates one series wound arc lamp, or when a shunt wound machine is employed to charge one set of accumulators; but you will notice that in such cases there is but one device absorbing energy. Where there is more than one absorber the difficulty of keeping each of these in unison with the other compels the adoption of a one-factor regulation of the generator.

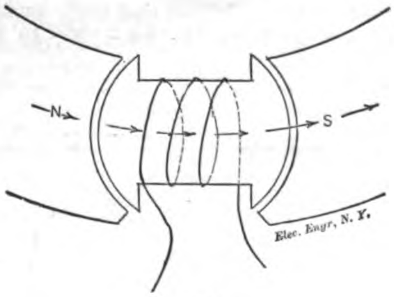

FIG. 1A.

The theory of the dynamo electric machine, as commonly taught, is that the electromotive force developed by any dynamo, depends on the rate at which the conductor under induction cuts lines of magnetic force. For purposes of this paper we will accept this theory; and as regulation of the output of a constant current dynamo means changing the electromotive force, we see that any method of regulation is necessarily a method of changing the rate of cutting of lines of force.

In practice this cutting is by the conductors of an armature revolving in a magnetic field, and we see several possible ways of obtaining a change of rate. We can change the velocity of the conductor, run the armature at a lower speed, and so do less cutting in a given time; or we can reduce the number of lines of force intersecting the path of the conductor, and so give the armature of the wires less lines to cut; or we can change the length of conductor, as the greater effective length of armature wire there is in the field, the more cutting it will do per revolution. Any of these, or any combination of them will serve to regulate the electromotive force.

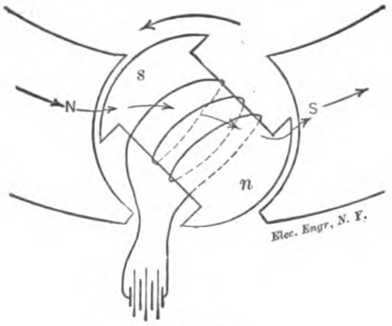

FIG. 1B.

The first way is the simplest and most efficient. Change of speed will alter the electromotive force of a dynamo, without complication and with absolute accuracy right down to the point at which it merely charges its own field magnets.

In water-power plants regulation by speed is common.

Regulation by changing strength of field has been brought to perfection in constant potential working, in the shape of compound winding. It is used also in constant current work, many of the most familiar devices depending primarily on change of field. But compound winding is not used to any extent, such winding for constant current being difficult. The first difficulty is to design a commercially and mechanically practicable shunt field for high voltages. Shunt wound arc dynamos have worked up to 1,200 volts, and worked well under favorable conditions. But 1,200 volts is too low for recent practice, and conditions are rarely favorable to an arc dynamo. With the open coil dynamos, which have two or three independent commutators connected in series, it is possible to compound by a shunt connected to one commutator only; the shunt thus taking half or one-third of the total voltage. Power generators of this type are doing excellent work, but the extreme changes of lead under variation of load, limit the applicability of these machines. Of course an automatic brush-rocker is suggestive as the one thing needed to make them generally useful, but to make a brush-rocker keep step with the instantaneous changes of field, is not easy. I believe that at present, when a sudden change of lead is required, the compounding acts quicker than the shifting brushes.

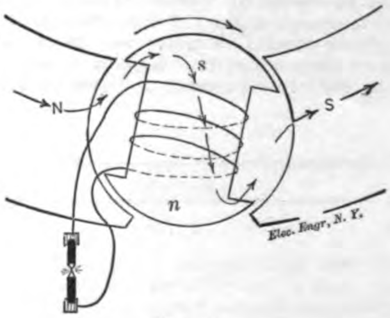

FIG. 1C.

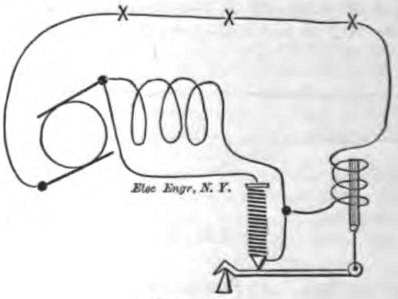

FIG. 2A.

Before taking up the study of regulators of the field changing class, I must say something about armature reaction, *i. e.*, the influence of the armature magnetism on the density of the field.

I want to make clear, by a few diagrams, the part which the armature of a dynamo constitutes in its magnetic circuit, and not begin by a definition of the magnetic circuit. I state its fundamental law, in order to lead up to the statements that follow. It is, that the magnetic flux in any circuit, that is, the total number of lines of force, or what we call the strength of field, is directly proportional to the magnetomotive force (ampere turns) and is inversely proportional to the magnetic resistance of the circuit.

Now, the magnetic circuit of a dynamo is a compound one. It is not all iron, or all air; it is iron and air and copper armature wire. The magnetic flux in this circuit under a given magnetomotive force, applied to the field magnets, can be caculated, when the armature is not traversed by current, from the known magnetic resistances of the iron and air and copper. But so soon as there is current in the armature the circuit becomes complex as well as compound. The armature becomes a magnet in its own right in virtue of the current circulating in its windings, and its magnetism may, and does, oppose that of the fields. So that the total magnetic flux or strength of field is changed, and changes further as the current in the armature increases.

---

[1] Abstract of paper read before the Chicago Electric Club.

To illustrate this by my diagram. Fig. 1 *a*, let us conceive the armature to be free to move on its axis, but not traversed by current; and the field excited by a constant current from some external source. We have thus a magnetic flux from pole piece N to pole piece S, which takes as part of its path the iron core of the armature. Here we have an ordinary compound magnetic circuit.

Now we will conceive, Fig. 1 *b*, that the armature also is excited, from some internal source, in such manner as to produce polarization N and S. We have now a marked tendency to get attracted poles in line in such manner as to get the best magnetic circuit, to get the straightest path for the lines of force; or, we may say, in such manner as to form of the two independent magnets, the field and armature, one big magnet. This is what I call a complex magnetic circuit. There are two magnetomotive forces operating to produce a flux along the same path. Our diagram, as it stands, only needs a commutator and brushes to be a motor.

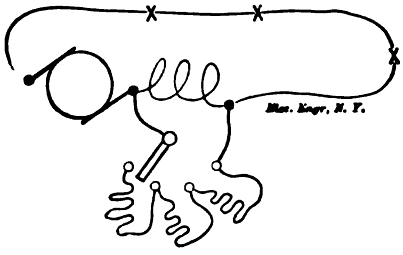

FIG. 2B.

Now we will conceive Fig. 1 *c*., that we have a belt on the armature pulley and are driving it up to speed, and that the ends of the armature coil are closed on one another, say, through an arc lamp. There will be currents induced in the armature coil, and these currents will polarize the core in such manner that each of its poles N. S. is attracted and held back by the field pole which it is leaving, and repelled by the field pole which it is approaching. That is, the work done in driving a dynamo, pulling attracted armature poles apart, and pushing them up to other poles which repel them.

Now let us examine the magnetic circuit as a whole. We have recognized the effect of the magnetic flux to secure the shortest path, the greater will be the flux. We will place the armature of our diagram in the position for maximum induction of current in its coil (Fig. 1 *c*.). The rotation is right-handed. Remembering that the pole of a dynamo armature which is leaving a field pole is always of the sign which that field pole would attract; we see that the upper armature pole is S and the lower N. Now let us lay out the course of the magnetic flux. We find that the lines which went straight across from N. to S. of the field magnet when the armature was not generating current, cannot do so now. They are repelled by the lower end of the armature and obliged to bend upward toward the upper end. I find it convenient to think of the reaction state as a lengthening of the magnetic circuit. The lines of force now take a crooked long path instead of the short straight path they had before the reaction commenced, and the effect on the field is just the same as if the magnets had been made longer, or the air space made wider. You do not get so strong a field when reaction sets in, although your exciting current or magneto-motive force remains the same. Indeed, in dynamos designed to take advantage of this reaction you do not get so strong a field for a greater exciting current.

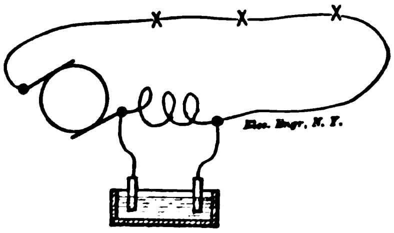

FIG. 2C.

The most familiar regulators of the field-changing class are those in which an adjustable resistance is connected in shunt to the field winding of a series dynamo as shown in Fig. 2 *a*, *b*, and *c*. We notice that wherever this is in successful use, the variation of the resistance is controlled by a small relay in the main circuit, and that the heavy mechanical work of the device is performed by magnets in a local circuit, or by the power driving the dynamo. The requirement for good practical regulation of an arc circuit, is that the relay shall be more sensitive than the arc lamp. It is frequently so delicate that it responds promptly to a variation of current of 1/4 of 1 per cent.

In Fig. 3 is shown another way of varying field magnet strength. It is in use on the Hochhausen dynamo and motor, and is quite accurate when the field is divided into many sections. A similar arrangement where the field coils, instead of being altered in number, are subject to permutations and combinations that vary the number in series, is in use on two systems of series wound street car motors. This does not work so well as the Hochhausen plan, because it is limited to a few gradations, and it is usually combined with a resistance called an "an easy-starting-coil" to make it less jerky in its operation.

Some of you may have been accustomed to think of the reduction of electromotive force under field regulation as due only to change of exciting current. The changes of lead under such regulation should indicate the actual process to an observer, but not one published description takes account of anything but the fall of field current. If you wish to understand clearly the process, I suggest that you put an armature in the field circuit of your dynamo. You will possibly find a reduction of electromotive force of 90 per cent. to follow a reduction of only 45 per cent. in the exciting current.

We come now to consider that class of regulators which operates by moving the brushes of a closed-coil armature. The most common explanation of this regulation is by the well-known "diagram of potentials," showing that near the neutral point the brushes are on the diameter of maximum difference of potential, and that 90 degrees distant, they would find a diameter of equipotential, and of course that any desired intermediate potential difference can be had on the proper intermediate diameter. And you can, by using a voltmeter—not the brushes—get just such a diagram of any of these machines; so of course the explanation is complete. But I have harbored for a long time the suspicion that this explanation did not explain. And this was what aroused my suspicion. I looked at the diagram and saw that if I rocked forward those brushes 45 or 50 degrees, I would get just half the maximum potential. Then I looked at a machine and found that if I rocked forward the brushes 45 or 50 degrees, I didn't get any potential at all. Then I looked at more machines, and more and more of them, and they all had this utterly unjustifiable departure from the diagram. I went to work on a 400 ampere machine with a voltmeter, and got a beautiful potential curve. Then I calculated the position which would give me 5 per cent. reduction in voltage, rocked the brushes forward, and got a 10 per cent. reduction. And so it was in every position in which I could try it.

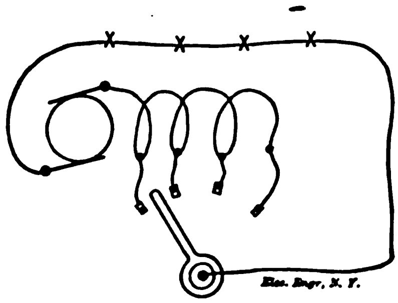

FIG. 3.

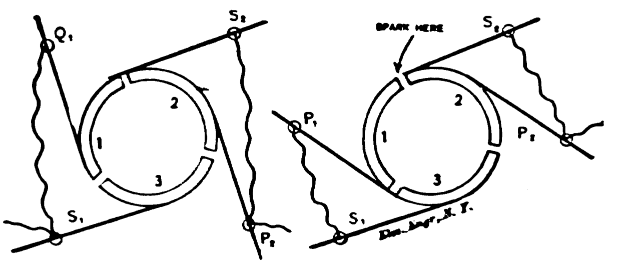
Then I got hold of a series wound dynamo and run it on a resistance. I rocked the brushes backward and forward as far as the spark would permit, and found that I could vary the current from maximum about 40 per cent. downward. Then I tried what effect varying the field current would have in comparison with changing the lead, and I found that variation of field current very much inferior, a little change of lead would neutralize all the variation I could control.

Here were two machines that had but one thing in common with the arc dynamos, namely, a strong armature compared with their fields. And they showed the same quality of regulation by brush rocking as did these special arc dynamos. My suspicion was becoming a theory at a rapid rate. And so I formulated the theory that regulation by brush rocking depended on armature reaction, and that consequently the essential condition to success under this method was a magnetic circuit in which the armature magnetism had large value in comparison with the fields.

Now there is one more method of constant current regulation in use that cannot be left out of any paper on this subject. It is regulation by changing the effective length of armature conductor, and its sole representative is a well-known open coil dynamo, the Thomson-Houston. You are doubtless familiar with the brush arrangements of this peculiar machine, and know that its regulation of E. M. F. is by a device which short circuits the armature. But to assist your remembrance, I have here two diagrams showing in Fig. 4 the full load and in Fig. 5 the minimum load positions of the brushes and their contact with the segments at these positions. Notice that in the minimum position the armature is absolutely short circuited from brush to brush during half of the revolution. That is, it is short circuited six times in each revolution and each time during 40 degrees of its movement, a total of 180 degrees. This period of short circuit is gradually reduced in its duration, although it still occurs six times per revolution, until the full load position is reached, when it is almost nothing. It would be absolutely nothing if it were not for the spark. The metallic contact is broken, but the spark under the tin of the secondary brush has conductivity like any other electric spark, and so gives a momentary short circuit.

The actions following the short circut of active armature coils are complex. We expect the most noticeable to be the development of a tremendous current in the short circuited coils with great heating, and our experience with short circuiting of individual sections of armatures would lead us to predict the early destruction of the winding from this coil. The facts do not bear out the predictions. The enormous short circuit current begins to develop but meets reactions which arrest its growth.

We have seen earlier in this paper that any forward change of lead signifies a lengthening of the magnetic circuit, and a consequent reduction of the field value. Thus the regulation is affected not only by removal from circuit of the conductors cutting lines of force, but also by actual reduction of the number of lines of force in the field. And further, this reduction of field is due both to a decrease in magnetomotive force, in that the exciting current becomes intermittent; and to increased resistance of the magnetic circuit in that the resultant polarity of the armature is displaced forward, virtually lengthening the path to be taken by the magnetic flux. The same reduction of field that affects the working circuit influences also the local circuit of the armature and aids in preventing any injurious increase of current or heating of the short circuited coils.



FIGS. 4 AND 5.

It will be asked why the operators of these dynamos avoid running them on a few lamps, and what cause there is for the frequent statement that they heat when working on a minimum load. The explanation is simple, if we again consider the action a periodical or intermittent currents.

We observe that as the load decreases the short circuiting becomes more lengthened and the currents delivered to the field coils becomes more markedly intermittent. These coils are wound on an iron core, and it is to the iron we must look for the heating. It is in exactly the same relation to the field coils as are the secondary winding and iron core of an induction coil to its primary, and it is not laminated as is the core of the induction coil, nor is it, like the secondary, provided with an external circuit for the utilization in external work of the currents developed in it. It is to these induced or Foucault currents, that we must attribute the heating of the dynamo at short loads.

The last point I can take up in this paper is the influence which the work a dynamo is doing has upon its regulation. Of course the work of a dynamo can be expressed as so many watts, no matter how the current is employed, but practical men recognize that certain classes of work, though they may not exceed in watts certain other classes are much more severe on the machine, and trying to the regulation. The motor circuit is notoriously the hard one; but many practical men have noted that there is a difference in facility of regulation with different arc lamps in circuit. Thus the differentially wound arc lamp, with a strong magnet in the main circuit is an easy lamp to regulate for. The discharge from the series magnet helps the dynamo during a momentary overload, and so does the shortening of the arc. But the shunt wound arc lamp is just the reverse. The discharge from its magnet goes through its own arc and for all small changes of current its action is to lengthen the arc for a decrease and shorten it for an increase, and so put more work on the dynamo regulator.

In conclusion I would suggest to you the adoption of the expression I have used for the armature reaction effect, namely: *Lengthening of the magnetic circuit.* I submit that the expression has the following advantage—it explains the observed effect—it conforms to the now generally received law of the magnetic circuit—it can be expressed in terms of magnetic resistence, just as can the effect of any other change of magnetic circuit—it admits readily of graphic illustration—and can be shown by an iron filings card taken from an actual dynamo.

The terms *armature reaction* and *cross magnetization* do not fit with the idea of the magnetic circuit. The expression of the effect as so many negative ampere turns has been employed but it is confusing to consider a condition as a reduction of magnetomotive force when that theoretical condition is accompanied by an actual increase of ampere turns. I propose to count all ampere turns of field and armature as positive, and to express the reduced magnetic flux following distortion of field as due to increased length and therefore resistence of the magnetic circuit.

THE PATENT CENTENNIAL CELEBRATION.

THE beginning of the second century of the American patent system was celebrated with due honors last week at Washington, by a convention of inventors, manufacturers, patent attorneys and others. The meetings extended over three days, and were well attended. The first public session was opened by President Harrison. A large number of interesting and valuable papers were read, and such as bear upon electricity will be found in full, or abstracted, in our columns this week. The proceedings were interspersed with receptions, excursions, etc.

PROF. THOMAS GRAY, of the electrical engineering department of the Rose Polytechnic Institute delivered an address on the "Inventors of the Telegraph and Telephone." It was of a very interesting nature, and historical in its treatment of the subject. He did not consider that any one man was entitled to the credit of inventing the telegraph.

In speaking of the relations between invention and research, **MR. F. W. CLARKE** said that a hundred years ago, in 1791, Galvani published his book on animal electricity, and at nearly the same time the Royal Society awarded the Copley medal to Volta. Between these events and the foundation of our patent office there was no obvious relation; but the science grown from those germs is now one of its chief objects of activity. At the time they were made, Galvani's work had no practical significance, and many other illustrations were cited by the speaker to show that applied science always has its roots in researches of a purely abstract nature. We can have no applied science unless we have the science to apply, and as it happens that the nations which encourage scientific investigations, acquire thereby industrial supremacy. The agencies which develop research are individual enterprise, schools and universities, scientific societies, and government aid. Of these the university is the chief, and in the university laboratories nine-tenths of the purely scientific discoveries are made. A true university is a producer as well as a distributor of knowledge, and by recognizing this fact Germany has become the leader of modern science. A chemist who has done no original work can have no prominent position in Germany. The speaker urged that training in pure research be more cultivated than hitherto in American schools, where now the so-called "practical view" prevails. The student should learn how to discover; how to solve unsolved problems; for that is the mainspring of modern industrial growth. Of Government aid to science the speaker said little, except to show that the relation was a material one, and that in receiving help from science the state should render help in return. He then went on to speak of the gaps in our knowledge, due to the individualism of workers, each laboring for himself without reference to what others were doing. Co-operation is necessary, and along lines where the inventors and manufacturers can help. There should be established laboratories for research, in which the problems too large for individual effort could be properly handled, and important physical constants determined. Such constants are of fundamental importance to pure and applied science alike, and their measurement should not be left to personal convenience. Some of the wealth reaped by the inventor from applications of science might well go back to its source as seed. The research laboratory, in which the workers need not be overloaded with other duties, is the great desideratum for chemistry and physics to-day.

PROF. R. H. THURSTON read a payer on the "Builders of the Steam Engine," as the founders of modern industries and nations. He remarked that "Since Watt, the work of improvement of the steam engine and its introduction has been largely done by American inventors, under the protection of the patent laws of the United States; and the country has reaped a magnificent harvest, as a result of this discreet sowing of seed in earlier days. Corliss made the modern steam engine, availing himself of a principle given the world by Frederick Sickels, and Fulton gave us steam navigation. The Stevenses carried into effect the ideas of Fitch, and a dozen inventors and constructors made successful the plans of the Stephensons in the building of the railways. And so, to-day, a ton of engine does the work of ten of the time of Watt; a pound of fuel gives ten times the power obtained from it in his day; a steamer now crosses the Atlantic in one-eighth the time demanded at the beginning of the century; avoidable wastes in the engine have been reduced from 80 per cent. to 8; a half ounce of fuel will transport a ton of cargo over a mile of ocean.

JUDGE ROBERT S. TAYLOR read a paper on "The Epoch Making Inventions of America." With regard to electricity he remarked that since Franklin drew the first submissive spark from Heaven, Americans have been foremost in the great field of electricity. The subjugation of this great force was begun when Prof. Morse taught it to talk. The steam engine is the breath and muscles, the telegraph the nervous system of the body politic.

In the production of electric light, man has come nearer to creation than anywhere else. He has produced upon earth the light of the heavens—a true sunlight in fragments. But the most gratifying of all inventions is the telephone. It imparts a new function to speech and a new sense to the ear. It introduces the epoch of neighborship without propinquity, and lengthens life by saving time.

The patent system of the United States rests on 22 words in the Constitution. What other 22 words ever spoken or penned have borne such fruit of blessing to mankind?

In his paper on "The Effect of Invention on the Railroad and other means of Communication," Mr. Octave Chanute, president of the American Society of Civil Engineers, said: Upon the land, inventors talk calmly of superseding the present maximum railroad speed of 70 miles an hour, with velocities at 120 to 150 miles per hour. Recent developments in electrical science have given good hopes for this, and both European and American inventors are experimenting. Among the latter may be mentioned the "Weems Electric" system, by which speed of 115 miles per hour have already been attained on a most imperfect track; the "Williams Port-Electric" system, of attracting forward at high velocities, a railroad car forming a magnetic core through a series of helices or coils charged with an electric current, and the "Chemin de Fer Glissant" or water borne railroad cars, which was exhibited at the Paris Exposition of 1889. Allusion may be made to the "Bicycle locomotive," with which it is claimed that far greater speed can be obtained than with the engines in general use; the principal object of inventors in every case, seeming to be to gain higher velocities than these which have hitherto been found practicable.

In the air, man gazes at the birds, and longs to imitate them. I know, personally, of eight or ten perfectly sane men in the United States, in England, in France, in Australia and in Egypt, who are experimenting with flying machines. Not dirigible balloons, with which a measure of success has already been accomplished, although only low velocities are to be expected from them, but real flying machines, depending like the birds upon the sustaining reactions of the air for their support.

Of these experimenters, probably the best equipped is Mr. Maxim, the inventor of an electric light and of the automatic machine gun, who made the remarkable statement last November, in a letter to the New York *Times*, that his experiments show that as much as 133 pounds may be sustained in the air by the expenditure of one horse-power; that he has succeeded in making a motor which will develop one horse-power for every six pounds of weight, and that a speed of 100 miles per hour would seem to be attainable.

If his experiments, which are now being carried on in England, on a large and skilful scale, succeed as he hopes, or is some other of the many inventors who are working on the problem, hits upon the right combination, there seems to be no reason why man may not emulate eventually the flight of the swallow, whose speed is computed at 150 miles per hour, or that of the swift or martin, which is said to flash through the air at the rate of 200 miles per hour.

At a meeting on Friday night of a large number of the inventors and manufacturers of patented articles, who had been attending the patent centennial celebration, a national association of inventors was formed and a constitution and by-laws adopted. Persons may become active, honorary, and associate members, and life members by the payment of $100.

Dr. Gatling, the inventor of the Gatling gun, was chosen President, and Gardiner G. Hubbard of Washington, Prof. William A. Anthony, President of the American Institute of Electrical Engineers; Thomas Shaw of Philadelphia, and the Hon. Benjamin Butterworth, of Ohio, were elected Vice-Presidents.

College Notes.

WORCESTER POLYTECHNIC INSTITUTE.

The course of electrical engineering at the Worcester Polytechnic Institute, occupies a period of four and one-half years, being for three and one half years identical with that of mechanical engineering. Ample accommodations for work in this department, and a full equipment of instruments and apparatus, are provided.

The Institute has received a gift from the Westinghouse Co. of two dynamos and a motor, together with lamps, switches, etc. The annual catalogue for 1891 shows the total number of students in the Institute to be 196. Prof. A. S. Kimball, Ph.D., of the Physical department, has charge of the electrical studies. Three students are now taking the special electrical studies.

Letters to the Editor.

WHO COINED THE PHRASE "DYNAMO-ELECTRIC MACHINE?"

To whom is rightfully due the credit of the introduction of the convenient and expressive term "Dynamo-Electric Machine?" Professor Silvanus Thompson, who is usually good authority, says in his treatise that the name "appears to have been employed by Dr. Werner Siemens, in his communication of January 17th, 1867, to the Berlin Academy, in which he described a machine for generating electric currents by the application of mechanical power, the currents being induced in the coils of a rotating armature by the action of electric currents which were themselves excited by the currents so generated." But, as a matter of fact, this paper which is in *Monatsberichte Akademie* (Berlin), 1867, p. 55, entitled *Ueber die Umwandlung von Arbeitskraft in elektrischen Strom ohne Anwendung permanenter Magnete*, and may also be found in translation in Keith's Schellen's *Magneto and Dynamo-Electric Machines*, I, 180. makes no mention of the term "dynamo." It appears, however, that William Ladd read a paper in March, 1867, before the British Association "*On a new form of dynamo-magnetic machine*" (see Brit. Assoc. Rep. xxxviii, 18 [1867]) and another one the following year entitled "*On a further development of the dynamo-magneto-electric machine* (Ibid, xxxviii, 19). Ladd also exhibited one of his machines, having a single field-magnet charging two armatures, one for maintaining the field and the other for doing the external work, which was placarded "*Dynamo-Magneto-Machine.* New Principle of Conversion of Dynamic Force," in the English section of the Paris Exposition of 1867. I have not succeeded in finding an earlier use of the term than that by Ladd above referred to.

April 8, 1891.

THE COMMERCIAL FUTURE OF THE TELEPHONE.

It is generally believed by the public and by many inventors of telephonic apparatus, that, after the expiration, in 1893, of the famous Bell patent of March 7, 1876, the lawful monopoly now held by the American Bell Telephone Company will expire by limitation.

The hopes and expectations of the long suffering public are doomed to disappointment. The *present* monopoly of telephony, held by the American Bell Telephone Company under the Bell patent, will cease when that patent expires, but that company long since acquired inventions which will control absolutely the use of all forms of the microphone, which is the only and essential instrument now known by the public for the transmission of speech by means of electricity under the Bell system, which the Supreme Court said "consisted in the use of an undulatory current in a closed circuit," and to the use of that instrument the world is indebted for the practical use of the electric telephone.

The Supreme Court of the United States, in the opinion delivered on the 19th of March, 1888, said:

"Bell discovered that speech could be transmitted by gradually changing the intensity of a continuous electrical current in a closed circuit; but, if another discovers a different method or way of doing the same thing, and gets a patent for it, the two discoverers will be permitted to operate each in his own way without interference with each other."

It is sincerely to be hoped that the inventive genius of some of our electricians will soon discover that "different method," and relieve the public from the exactions of the great monopoly.

The microphone is the only instrument *now known* which will transmit speech in a practical way, and the owners of that instrument will continue to control the practical use of the telephone in the United States. Thousands of microphones, of various forms and shapes, have been invented, but they all will be subservient to the patent, which will hereafter be issued to the American Bell Telephone Company for the microphone.

The microphone was claimed in a caveat, filed in the Patent Office on 14th April, 1877, by Emile Berliner. The claim is in these words:

> In an instrument situated within an electric circuit, having two or more ends of the circuit brought in contact with each other, which points of contact can be loosened or tightened by vibrating one or both sides of each contact, thus diminishing or increasing the current of electricity passing through the contacts as many times as vibrations occur.

This claim describes the microphone, and is so broad and so clear that it covers all forms of microphones now known or which may be invented, and without the microphone, the present Bell telephone system is not a commercial or practical one.

Patentees of microphones now, for the first time, learn that their patents are worthless, and that the American Bell Telephone Co. own this invention, and that company also owns the invention of Thomas A. Edison of a similar instrument, for which he filed an application for a patent on 20th July, 1877. No patent for the microphone has been issued to Berliner or Edison under their application, for the reason that those two claimants were put in interference by the patent office, and the important point is that the interference has been kept alive, and has not been decided by the patent office.

The American Bell Telephone Co. owns both these inventions, and the decision of the patent office can be deferred from year to year by that company, as long as it may deem best for its interests, and that company, no doubt, will defer asking a decision from the patent office until a short time before the Bell patent of March 7, 1876, expires, and then a patent for the microphone will be issued for Berliner's method to the American Bell Telephone Co., which will run for seventeen years from the date of issue of the patent, thereby securing to that company a continuance of its monopoly until 1910, unless, as the Supreme Court said, "another discovers a different method from that of Bell."

It is hoped men of science and intelligent mechanics will endeavor to discover that "different method."

W. C. BARNEY.

BALTIMORE, April 4, 1891.

OWNERSHIP OF THE WHELESS PATENTS.

We observe in your issue of April 1st an article headed "The Wheless Underground Electric Company." This article states that the Wheless Underground Company, of Tacoma, incorporated with a paid up capital of $500,000, had recently come into possession of all Mr. Malone Wheless' interests in his electric railway inventions, and that these inventions cover the overhead and conduit systems, and furthermore, that THE ELECTRICAL ENGINEER some months ago fully described these inventions.

We must confess our great surprise that your journal should publish the above statements, cognizant as you must be by the business relations sustained with the undersigned company, that the patents above referred to are the exclusive property of The Wheless Electric Railway Company, of Virginia. We are very sorry that such statements as the above should have been published upon the authority of an irresponsible party, when a simple inquiry from the officers of this company would have elicited the response that The Wheless Electric Railway Company, of Virginia, owns and controls absolutely all of Malone Wheless' inventions for electric railways, both overhead and underground, and furthermore, the records of the U. S. Patent Office will disclose the fact that all improvements by Malone Wheless upon these systems are also the property of the undersigned company.

In order that the public be not deceived by these misleading statements, or the correspondence belonging to this company be diverted from its legitimate channel, by the article complained of, we request that you publish in your next issue the facts herein stated, and furthermore, that Malone Wheless has no interest in the said inventions to dispose of, such interest having long since been acquired by this company, and that this company will prosecute all parties infringing these patents.

THE WHELESS ELECTRIC RAILWAY COMPANY,
D. F. MERRILL, JR., *Secretary.*

WASHINGTON, D. C.

THE WHELESS ELECTRIC RAILWAY SYSTEM.

In the *Portland Oregonian* of April 2, 1891, appeared the following advertisement:

THE WHELESS ELECTRIC RAILWAY SYSTEM.—WARNING.

The public is cautioned that all the patents and inventions of Malone Wheless for overhead and underground railway systems are owned and controlled exclusively by the Wheless electric railway company of Virginia (office Washington, D. C.), and that any company using either of said inventions is liable to action for infringement. Special notice is hereby given that no licenses have been granted and that no person is empowered to grant licenses. The Wheless Electric Railway Company, D. F. Merrill, Jr., Sec., Washington, D. C.

When the promoters of the Wheless Underground Electric Company were preparing for organization they investigated fully the field of inventions relative to electric street railway systems and during this investigation became aware of the Company which is responsible for the above publication. We found that the company referred to had apparent title to sundry patents relating to improvements in electric street railways, the inventions being those of Mr. Malone Wheless, of Nashville, Tenn. We found upon further examination that the Company referred to held its titles under executory contracts with Mr. Wheless, and that Mr. Wheless had brought suit against that Company in the Circuit Court of the United States for the Eastern District of Virginia to cancel these contracts, and that suit is now pending. The devices covered by the patents of that Company, as far as we are concerned, are obsolete and not adapted to the work for which our Company was organized.

The result of this suit in no wise affects or concerns our patent interests as we are working under electric railway patent interests which are fundamental in their character and have no relation whatever to any patents now in the possession of the Company above referred to. While for business reasons the transfers of patents which the Wheless Underground Electric Company proposes to use in their work, have not been spread upon the records of the Patent Office, we have no objection to their becoming known, either by the Wheless Electric Railway Company of Virginia or the public.

We are surprised at this notice since we are fully aware that the Virginia Company cannot understand the nature of the patents which the Underground Company are working under.

WHELESS UNDERGROUND ELECTRIC CO.,
By A. A. HONEY,
Vice-Pres't & Gen'l Mgr.

Reports of Companies.

WIGHTMAN ELECTRIC MFG. CO.

President Harrison's son-in-law, Mr. J. R. McKee, has just been elected president of the Wightman Electric Manufacturing Company of Scranton, and the concern, which is affiliated with the Thomson-Houston Company, proposes to engage extensively in the manufacture of electric mining apparatus, for which there promises to be a great demand within a short time in the anthracite coal fields of Pennsylvania. The Wightman Company is at present engaged in the manufacture of electric street-car supplies at its Scranton establishment, but with the application of electricity to mining it expects to occupy a large and profitable field of usefulness.

Mr. McKee enters the Wightman Company as one of the representatives of the Thomson-Houston interests, the other representatives of the same interest being H. M. Byllesby, O. T. Crosby, and Winthrop Coffin. Messrs. Lathrop R. Bacon and J. B. Newcombe, of New York, and the Hon. Alfred Hand and Col. George Sanderson, of Scranton, withdrew recently from the Directory to make way for these gentlemen. The other officers are Merle J. Wightman, vice-president and electrician; Herman Bergholtz, general manager and consulting engineer; and Horace E. Hand, secretary and treasurer.

It is claimed that inventions are now in course of development that will greatly facilitate the general introduction of electricity in the work of mining. The Wightman Company will control the patents connected with these inventions.

ELECTIONS.

DERRY, N. H.—Prof. E. K. Angell has been elected president of the Derry Electric Light Company.

BROOKLYN, N. Y.—The annual election for officers, directors and inspectors of election of the Brooklyn Electric Light and Power Company resulted as follows: Directors, Thomas Black, Stephen J. Burrows, Charles A. Smylie, Theodore Dow, Edward S. Seeley, Henry H. Downes, Adolph E. Smylie, E. Smith Nevins, Augustus P. Avery. Inspectors of Election, James Davey, Jerome Taylor, Walter A. Pendleton. The following are the officers: President and general manager, Charles A. Smylie; vice-president, Stephen J. Burrows; secretary, Thomas Black; treasurer, Adolphe E. Smylie.

DIVIDENDS.

NEW YORK CITY.—The local Edison Electric Illuminating Co. has declared its twenty-fourth quarterly dividend of 1 per cent. payable May 1.

Appointments, Etc.

MR. GEORGE EMMET has recently been appointed superintendent of the Attleboro Electric Railway.

MR. CHARLES HARRY, late superintendent of the Bay City, Mich., Electric Railway, has accepted a similar position with the Eau Claire, Wisconsin, Electric Railway Light and Power Company.

MR. W. A. GILES has been given charge of the mill, mining, marine and metallurgical departments of the Edison General Co.'s Eastern district.

MR. R. R. TOVEY has handed in his resignation as electrician for the Butte, Mont., Electric Light Company. Mr. Tovey has been in the employ of the company for the past five years.

MR. L. H. KINNARD, JR., of Harrisburg, has succeeded Charles A. Matcham, as manager of the telephone exchange in Lancaster, Pa.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED APRIL 7, 1891.

Alarms and Signals :—

Automatic Electric Block System, J. A. Carlton & H. L. Johnston, 449,731. Filed Dec. 8, 1890.

A system of indicating by the automatic making and breaking of electric lighting circuits the presence of a train in a block division of a railway, or the exit of a train therefrom.

Automatic Railway Signal, C. W. Wilhelm, 449,990. Filed Sept. 23, 1890.

A device by which a signal is set at a certain station by a passing train, partially released when the train has passed a specified point and wholly released when the train has passed a more distant point, the train having set a second signal after partially releasing the first signal, but before wholly releasing it.

Train Signal, H. J. Finn & J. A. Garner, 449,672. Filed Nov. 14, 890.

Provides means by which the conductor and engineer of a train may be in direct communication at all times.

Non-Interference Electrical Signaling Apparatus, A. Newman, 449,690. Filed Feb. 28, 1890.

A signal-box and system applicable to district telegraphs, fire-alarms and police-circuits.

Auxiliary Fire Alarm and Extinguisher System, E. L. Slocum, 449,829. Filed Jan. 14, 1889.

Provides a system of alarm bells distributed about a building and a connecting system of water pipes and distributing heads, by which an alarm may be sounded in case of fire and any department or division of the building may be flooded with water.

Bell, A. F. Stanley, 449,832. Filed May 29, 1890.

Relates to the construction of the armature and hammer which are integral ; the hammer disc at the end is perforated and a peen of other metal is attached for striking the bell.

Automatic Bell Ringer, W. W. Slater, 449,866. Filed Jan. 6, 1891.

A combination of pneumatic and electro-magnetic apparatus for an alarm bell.

Conductors, Conduits and Insulators :—

Electric Connector, G. K. Wheeler. 419,721. Filed Nov. 26, 1890.

For connecting conducting wires to relatively large conductors such as railway rails. Consists of a tapered thimble or spool having a solid driving head and split for a portion of its length to form spring-jaws for clamping the wire when the spool is driven into an opening.

Insulator, L. McCarthy, 449,943. Filed Jan. 16, 1891.

Consists of a bell or case adapted to hold a series of sheets of mica, a metallic supporting piece placed therein, and a series of sheets of mica surrounding such piece and insulating it from the bell or case.

Dynamos and Motors :—

Automatic Switch for Electric Motors, W. Baxter, Jr., 449,660. Filed Oct. 21, 1897.

Relates to the class of "cut-outs" adapted to prevent the burning out of insulation and wire in a constant potential motor or dynamo by an excessive current ; the device shown and described is adapted for starting a motor or dynamo by hand and for opening the circuit automatically should the strength of the current exceed a safe limit.

Commutator for Electric Motors, H. Duenner, 419,774. Filed Oct. 16, 1890.

Consists in mounting the brushes upon a spindle which is movable longitudinally and applying cross head slides and an adjusting screw so that by a single turn of the screw the brushes may be adjusted longitudinally. To prevent the wearing of the commutator in circumferential grooves.

Electrolysis :—

Apparatus for Electroplating Small Articles, F. W. Zingsem, 449,890. Filed Oct. 17, 1890.

In a solution tank a shaft is supported in conducting bearings of the tank and a rotary reticulated drum of non-conducting material is attached to the shaft ; a conducting wire is connected to the shaft and is extended spirally through the drum.

Galvanic and Thermo-Electric Batteries :—

Carbon Electrode for Electric Batteries, E. A. Le Sueur, 450,105. Filed Oct. 14, 1890.

Consists of a number of pieces of rough carbon cut to unequal lengths and having rough uncut sides, and a metallic backing in which the carbon pieces are embedded at one end.

Lamps and Appurtenances :—

Electric Arc Lamp, E. Thomson and E. W. Rice, Jr., 419,715. Filed Apr. 9, 1885

Relates to means for feeding the carbon rod or pencil by a clutch, clamp or feed device acting directly upon the carbon rod or pencil instead of upon the metallic rod or bar to which the carbon is usually attached.

Cut-Out, A. T. Tregurtha, 419,767. Filed Feb. 25, 1889.

Details of design and construction of a cut-out shown as applied to an incandescent lamp.

Circuit Breaker for Incandescent Electric Light Systems, F. Müller and J. G. Greene, 449,780. Filed July 23, 1890.

Designed to check the consumption of current upon circuits that are not provided with a meter. The device is designed to permit a predetermined number of lamps to burn without interruption, but it will immediately break the circuit and extinguish the lamps if more than the predetermined number of lamps are turned on.

Electric Cut-Out, A. T. Tregurtha, 419,921. Filed Apr. 17, 1890.

Design and construction of a cut-out shown as applied to an incandescent electric lamp.

Electric Lamp for Street Lighting, H. H. Carpenter, 450,000. Filed Feb. 19, 1891.

A portable electric lamp and post for street lighting and similar purposes. Includes a case or closet forming the main stem of the post, fitted with shelves to contain storage batteries.

Cut-Out, J. S. Gibbs, 450,101. Filed Feb. 11, 1891.

A cut-out for multiple incandescent lamps.

Measurement :—

Ammeter or Voltmeter, H. C. Shubert, 449,766. Filed Oct. 31, 1890.

Consists in the combination, with two opposed soft-iron plates enclosed within an encircling coil included in the electric circuit, one of which is fixed and the other secured to a spindle carrying an indicating pointer, of a coiled spring governing the spindle and a regulating lever controlling the spring for its adjustment ; the spring operates when adjusted to produce a contact of the soft iron plates, so that the repulsion of the plates when magnetized by a current in the coil may be measured by the tension of the spring to indicate the amount or force of the current.

Metallurgical :—

Process of and Apparatus for Separating Ores Electrically, C. M. Ball & S. Norton, 449,726. Filed June 30, 1890.

Amplification of the invention patented to the same persons June 10, 1890, No. 430,058. The present invention consists in passing the crushed or granulated mass through a consecutive series of magnetic fields, while impressing on the mass degrees of tangential inertia differing in the successive fields of magnetic force.

Metal-Working :—

Method of Electric Welding, E. Thomson, 449,836. Filed July 11, 1890.

Designed to preserve the original character of the metal, adjacent to a joint, without changing the cross section of the finished work. Consists in expanding or upsetting the metal of the work either before or after the welding operation, and then employing rolling, or other reducing operation for restoring the character of the metal.

Miscellaneous :—

Electrical Hoisting Machine, W. Baxter, Jr., 449 661. Filed Mar. 2, 1888.

Consists mainly in the combination of a motor having only two magnet cores with a drum and worm-gearing upon a single bed, the whole forming a complete organized portable machine and the bed forming the bridge or yoke of the two magnet cores. Details relating to other features are included.

System of Operating Electric Elevators with Landing Switches Only, W. Baxter, Jr., 449,662. Filed April 20, 1888.

Adapted to control the movements of a car or platform carrying no operator, such as dumb-waiters or freight-hoisting platforms.

Electrical Dental Engine, F. F. Eggers, 449,847. Filed Dec. 10, 1890.

Consists of a motor journaled and rotating directly in the movable bracket of the apparatus, means for stopping and reversing the motor and for disengaging it from the mechanism.

Electric Valve Controller, G. E. Turner, 449,889. Filed Aug. 12, 1890.

Consists of a peculiarly constructed wheel operating with a step-by-step movement to reciprocate the valve, and an electro-magnetic apparatus for imparting the step-by-step movement to the wheel.

Lightning Arrester, J. W. Easton, 449,908. Filed Aug. 14, 1890.

An electro-magnetic apparatus energized by the passage of a lightning discharge separates the ends of the electrodes of the arrester sufficiently to avoid the formation of an arc and interrupts the circuit, upon which the electrode falls back to its normal position.

Electrical Lock, H. Grefen, 450,068. Filed May 19, 1890.

Peculiarly constructed bolts in combination with electro-magnetic apparatus for controlling them.

Railways and Appliances :—

Propelling Mechanism for Electric Motor Cars, S. H. Short, 449,709. Filed Dec. 11, 1890.

The armature of the motor is mounted directly upon the driving axle and the field magnets are mounted on short hanger-frames, pendulously suspended from the car axle, preferable between the wheels, so as to bring the journals close to the motor ; field magnets are held from rotation by a connection with another part of the car.

Electric Motor Car, H. P. Brown, 449,752. Filed May 26, 1890.

The armature shaft of the motor may revolve continuously, while the speed of the car and the amount of force communicated from the motor may be varied as desired or stopped altogether. Employs a grooved driving pulley receiving motion from the armature shaft and a grooved pulley by which motion is communicated to the axle, a rope connection between the pulleys and a rope tightener pulley.

Electric Railway, E. M. Bentley, 449,792. Filed Jan. 30, 1888.

Provides a trolley adapted to ride upon the supply conductor with a pulling wire or rope having a shifting point of connection therewith, so that the trolley can be pulled from one side or the other of the main conductor as desired. The patent also includes a switching device by means of which the trolley can pass from the main to a branch conductor without interference from the guards.

Electric Railway, R. M. Hunter, 449,797. Filed Dec. 15, 1888.

In a double track railway provides a conduit structure between the two tracks, having two slots, one for each track.

Electric-Car-Stopping Device, G. W. Blanchard, 449,843. Filed Oct. 16, 1890.

Consists of a locking device for the gears of an electric motor in combination with an electro-magnetic apparatus for normally holding the locking device out of engagement with the gear.

Trolley Support for Electric Cars, F. Robinson & P. W. J. Lander, 449,886, Filed Jan. 12, 1891.

Details of design and construction of the connecting devices between the roof of the car and the trolley arm.

Electric Railway, R. M. Hunter, 450,074. Filed May 29, 1889.

Employs a supply conductor and a working conductor connected in parallel and suspended upon the opposite sides of poles at an elevation above the track and so that the working conductor is adjacent to the track ; provides a laterally moving collector upon the car making a travelling contact with the suspended conductor upon its other side.

Telegraphs :—

Telegraphy, F. Anderson, deceased, 449,655. Filed May 31, 1890.

A system of automatic transmission.

Telegraphy, R. G. Brown, 449,897. Filed June 27, 1887.

Relates to synchronous-multiplex telegraphy. Provides a special connection for carrying away the static discharge, and utilizes that discharge for making a record at the sending station.

Telephones and Apparatus :—

Multiple Telephony, W. W. Jacques, 449,679. Filed Dec. 1, 1890.

Claim follows :

The combination, with three or more line wires of a telephone system at each end thereof, of an equal number of Muirhead condensers and an equal number of telephone loops, each of said line wires being connected with a separate armature strip in said condensers, and each loop being connected with two conducting strips in said condensers.

Electrical Switch-Board, J. B. Lyon, 449,685. Filed Nov. 20, 1890.

Relates to the manner of arranging the connecting wires behind telephone switch-boards of the multiple type, and designed to secure greater compactness.

Society and Club Notes.

NEW YORK ELECTRIC CLUB.

The annual election of officers of the New York Electric Club for the year beginning May 1, 1891, will be held at the Club House on Thursday evening, April 16, when the polls will be open from 5 to 8. The club has lately been enjoying large accessions of membership under the vigorous policy of President Madden, who has declined to serve again; and great interest is taken in the results on Thursday night, as at least two tickets are expected to contest the field.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the monthly meeting of the Institute to be held on April 21, at 8 P. M., at the headquarters, 12 W. 31st street, Mr. A. S. Brown, of Boonton, N. J., will read a paper on "The Electrical Extraction of Aluminum," illustrated by lantern slides. It is also expected that Mr. N. D. C. Hodges, Editor of *Science*, will bring before the Institute that evening his new theory and practice of lightning protection.

BROOKLYN INSTITUTE.

An interesting paper on the telephone will be presented before the Electrical Department on Friday, April 17, by Mr. E. H. Lyon, of the Metropolitan Telephone Co.

Legal Notes.

TROUBLE OVER AN ELECTRIC LAMP.

Mr. Fred H. Thwing, president of the American National Bank, of Arkansas City, Kan., which suspended recently, has been arrested on a United States warrant. The plaintiff, who is named Munson, charges that Oct. 1, he owned a half-interest in a patent electric lamp. Thwing visited Chicago and negotiated for Munson's interest, giving in payment a certificate of deposit for the amount on the American National Bank. The bank failed and Mr. Munson sent his certificate of deposit to Receiver Hatch, who refused to recognize it because Thwing had never made a record of it upon the bank's books. Thwing was taken before Judge Bonsall and his bond fixed at $10,000 for his appearance.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of April 11, 1891, from New York, Boston and Washington.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

A steady, persistent advertiser rarely knows dull seasons.

THE LOOMIS INCANDESCENT SYSTEM.

A very handsome and interesting catalogue has recently been issued by the Eureka Electric Co., of 18 Broadway, relative to the Loomis system of arc and incandescent lighting which they control. The catalogue is profusely illustrated with perspective and detail views of the apparatus, including dynamos, arc and incandescent lamps, switches, cut-outs, ammeters, voltmeters, rosettes, pendants, motors, etc. All the parts of the system are carefully described, the advantages and points of superiority being pointed out. At the end are given a number of testimonials, and a sheet is inserted showing a long list of installations.

TEST OF THE TAYLOR PRIMARY BATTERY.

In a recent test, made for the third lighthouse department, of the Taylor primary battery, a Lugo motor was run for 76 hours on one charge, and developed nearly ¼ h. p. continually. The expense for the solution during the 76 hours amounted to 12 cents. Experiment are now being made in order to select the best motor for revolving the lights on light ships.

Attention is called to the card of Messrs Taylor and Son, in our advertising columns. The battery is attracting unusual attention.

THE WIRT LIGHTNING ARRESTER.

The Electrical Supply Co., of Chicago, reports a growing sale for the Wirt lightning arrester. This protective device is being largely used in electric railway work, its simplicity and compact form making it especially suitable for use in exposed places and on rolling stock. "An ounce of prevention is worth a pound of cure," and the Wirt arrester has, it is pointed out, always this distinct advantage over the most ingenious arc breaking devices, it *prevents* the forming of an arc in the first place.

THE BRISTOL, TENN., BELT LINE RAILWAY CO.

The Bristol Belt Line Railway Co. and the Bristol Street Car Co. have been bought out by Mr. A. H. Leftwich, of Spartanburg, S. C., and Mr. W. A. Stadelman, of Philadelphia, Penn., who have already begun the work of consolidating these roads, and changing them to an electric railway, under the name of the Bristol Belt Line Railway Co. Mr. S. L. Nicholson has been made superintendent of the road, and a large force of men are now at work planting the poles, laying track, etc. The road will be over eight miles long, and five cars will be put in use at once. Compound condensing engines, and steel tubular boilers, will be placed in a brick power house, which is now being built. A frame car house 50 feet by 80 feet is being erected. It is expected that the road will be in operation by the middle of June. The "Rae" system will be used. Two 40 h. p. equipments, and three 30 h. p. equipments, and one 65,000 watt generator will make up the electrical equipment.

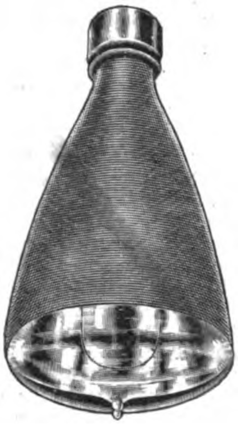
W. R. FLEMING & CO.

W. R. Fleming & Co., New York managers for the Foundry and Machine Dep't, of Harrisburg, Pa., have just put two of their engines into the H. C. F. Koch & Co. building, 125th street, New York city, which are to run four No. 2 dynamos. The engines are of the "Ideal" self-oiling type, which are meeting with great success in New York and vicinity. They run entirely in oil, a very novel feature in engines which engineers are beginning to appreciate. These engines were built to order on specifications furnished by the Koch Co. Like most of the engines furnished by the Fleming Co., these are 12" x 12" and 10½" x 10", neat and handsome in appearance, as well as heavy and serviceable for electric light duty. Koch & Co. will have no trouble with flickering lights. Fleming & Co. are building up a fine business in the installation of engines and complete steam plants and their success is mainly due to their experience, and that they let nothing but first-class work pass out of their hands. The Grand Central Depot plant is one of the first installed by them in New York, and is a very good sample of all their later work, being a perfect running plant. These engines, etc., are built at the factory at Harrisburg, Pa.

THE HALLETT LAMP.

THE demand for a first rate desk lamp that will throw its light where needed and not affect the user's eyes injuriously, seems to be filled very acceptably by an article being introduced by the Central Electric Co., of Chicago, and illustrated in the cut.

This lamp differs somewhat in shape from the ordinary incandescent lamp, its sides being almost straight, while the bottom, or large end, is as nearly flat as possible. These straight lines are necessary in order to obtain proper reflecting surfaces, and to prevent as much as possible, uneven intensities of light upon the object. The inside of the butt and the outside of the globe are silvered, and the incandescent filament is actually surrounded on three sides by a mirror reflecting all of the light downward. While the lamp may be placed on a level or a little above the level of the eye, no light strikes the eye directly from the lamp, as the silvering is covered and protected by an opaque substance. The lamp is made to fit any socket, and the new features are covered by strong patents.



THE HALLETT LAMP.

A NEW WASHBURN & MOEN ROLLING MILL.

The new rolling mill for the Washburn & Moen Mfg. Co., at Waukegan, Ill., will be quite extensive. The main building will be 140 ft. in width by 400 ft. in length, with a wing on one side 40 ft. in width and 160 ft. long, and one on the opposite side 40 ft. in width by 100 ft. long. The building will be entirely of steel, designed and built by The Berlin Iron Bridge Co., of East Berlin, Conn.

ELECTRIC LIGHT FRANCHISE IN SANTO DOMINGO.

The Government of Santo Domingo has granted a franchise for public and private lighting either by gas or electricity, for a period of 45 years, including rights of way on all the streets and highways of the capital of Santo Domingo. During the first ten years of this period the franchise is an exclusive one. The city of Santo Domingo has pledged itself to take 80 arc lights at $240 per annum, and to pay the same rate for all additional lights it may require. For each incandescent lamp it will pay $1.75.

It is estimated that over 1,000 incandescent lamps can be placed at once, and for private lighting the company is not restricted as to price. The suburb of San Carlos is also included in the franchise.

The owners of this franchise desire to open negotiations with parties, for the purpose of putting in an electric light plant, and offer liberal inducements to investors. Full information can be obtained by addressing the Editor of THE ELECTRICAL ENGINEER.

CLAY, PEPPER & REGISTER.

The above is the style of a new firm that has just been formed to do an electrical engineering and consulting business at 1,218–1,220 Filbert street, Philadelphia. They are also agents for the American Circular Loom Co. and the American Electric Elevator Co. The old firm of Clay & Pepper has carried on business in Philadelphia for nearly two years, and Mr. Register, who now joins it has been connected with the Railway Department of the Thomson-Houston Co. The new concern will make a specialty of wiring work.

OLD TIME TELEGRAPHERS.

About thirty old-time telegraphers assembled in the rooms of the Board of Trade, Washington, D. C., recently, to make preliminary arrangements for the entertainment, etc., of the members of the Old-Time Telegraphers' Society, which will meet in Washington next August.

THE SHAW ELECTRIC CRANE CO.

The removal of the Shaw Electric Crane Co. from Milwaukee to Muskegon, Mich., is announced, the contracts having been signed, and the company re-organized under Michigan laws. The shops are to be ready for occupancy early in August, and the company intend that they shall be the most completely equipped shops of their kind in the country. Business is very prosperous with the Shaw Company, and during the ensuing year they expect to more than double the output of last year. Among the orders received within two months are two cranes of ten tons capacity each, one for McIntosh, Seymour & Co., of Auburn, N. Y., and the other for the Whittier Machine Co., of Boston; one of five tons capacity for the Standard Elevator Co., of Chicago; and one for the Ball & Wood Co., of New York.

CLOWER, HARRIS & CO.

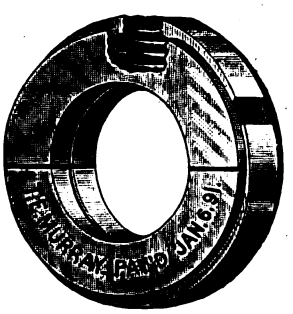
The old concern of Clower & Harris, of Dallas, Tex., has made a change of firm name and location. The new name, as given above, signifies the addition to the concern of Mr. E. T. Lewis, a well-known capitalist of Dallas. The new location is 289 Elm St., where they have fitted up the finest and largest electrical supply house west of the Mississippi river, with a large shop for repair work. The firm with its reorganization enters upon a career of greater activity and prosperity than ever.

THE GORDON SYSTEM OF ELECTRIC TRACTION.

The experiments carried out at Messrs. Merryweather & Sons, Tramway Works, Greenwich, England, on behalf of the Gordon Electric Car Syndicate, are said to have given encouraging preliminary results. The track has closed conduits, and the general idea of the system is a series of contacts actuated by means of an automatic magnet in a box placed in the ground every hundred yards or so—about 16 to a mile. The preliminary trials have been made in all sorts of weather, and with very severe tests, such as flooding the whole track of 70 yards with water, working in snow, fog, and so forth. The working pressure is 250 volts and the current 30 amperes.

METALLIC PISTON ROD PACKING.

THE accompanying illustration shows a novel metallic packing for piston rods, designed by Mr. T. E. Murray, of Albany, N. Y.



MURRAY METALLIC PISTON ROD PACKING.

The stuffing box is simply filled with the rings, the joints being broken by each ring, and then being screwed down tight. This packing is easily put in place, is automatic in its action, requires no attention, will not score the piston rod, and is extremely durable. It is manufactured by the Murray Metallic Packing Co. of Albany, N. Y.

THE JOHN SCOTT LEGACY MEDAL FOR INTERIOR CONDUITS.

Mr. E. H. Johnson, of this city, in a recent paper read before the Franklin Institute, gave an exhaustive description of the system in use by the Interior Conduit and Insulation Co., for house and underground wiring. His address, which was heard with much interest, appears in the journal of the Franklin Institute for March. In the same number is published the report of the sub-committee of the Committee on Science and the Arts, recommending the award of the John Scott Legacy Medal and Premium to the company. The recommendation was adopted by the committee. The sub-committee consists of the following: Carl Hering, chairman; T. Carpenter Smith, Richard W. Davis, E. A. Scott and Wm. McDevitt.

THE STANDARD ELECTRICAL WORKS, Cincinnati O., are enjoying an extensive and prosperous trade in electrical supplies of all descriptions. They are doing a large and growing street railway business, in which line they have many specialties. The present business in all departments is brisk, and the outlook very encouraging.

THE WHEELER BOILER AND WATER PIPE COVERING.

The great saving of fuel occasioned by the use of boiler and pipe covering has led to its almost universal adoption, even when, as is frequently the case, it is known to be inflammable, and is condemned by the insurance companies on that account, or when it has the property of eventually rusting the metal to which it is applied.

To overcome both these difficulties, Messrs. G. E. Wheeler & Co., of Piedmont, Ala., are manufacturing a material that, for the past six years, has enjoyed a constant and ever growing popularity. As a non-conductor and non-combustible covering it is claimed to have no equal. Being a fire-proof cement, applied directly to the boiler or pipes, it will not char or burn, and gives perfect safety from fire where pipes come in contact with beams or partitions. It dries in a few hours after applying, making a solid and cool surface, and has been used on boilers subject to all kinds of weather and exposed to both snow and rain, without any harm to the material.

The manufacturers are in receipt of the most flattering testimonials from steam users in all parts of the country.

NEW ENGLAND TRADE NOTES.

The Leach and Grant Co. has been organized in Boston with a capital of $50,000 to do a general contracting business. Mr. H. L. Grant is president, Mr. H. W. Leach, treasurer, and Mr. H. E. Grant, general manager. They will succeed to the business of H. W. Leach, & Co., and with the new capital will have facilities for largely increasing the business. The Leach and Grant Co. are masons, contractors and builders, and make a specialty of electric light and power plants. All three officers of the company have been for years connected with this class of work, and are well qualified to fulfil all work entrusted to them. Their headquarters will be, as before, at 243 Franklin street, Boston.

The Wainwright Manufacturing Company of Massachusetts have recently sold the following apparatus:—Two 300 h. p. compound engine heaters for the Municipal Electric Light Company, Brooklyn, N. Y.; two 120 h. p. surface condensers to the North Hudson County Railway, Hoboken, N. J.; one 300, one 200, and one 100 h. p. heaters to the Philadelphia branch office of the Ball engine company, for various electric light plants.

The Gould and Watson Co., of Boston, report that business this season is six weeks in advance of any heretofore. They have recently received some very large orders for insulators, and their factory is taxed to its utmost to get out the goods. They have just come into possession of one of their bell form of moulded mica line insulators which had been removed to make change in construction of line, from the overhead system of the West End Street Railway Company of Boston. This bell has been hanging for 2 years and 10 months, and was found on close examination to be as sound as ever, with no signs of disintegration. This particular insulator has been well tested in its position repeatedly and never showed any leakage.

The Standard Electric Co. of Vermont, have recently sold a 500 light and a 300 light dynamo to the Quincy Market Cold Storage Co. of Boston, and a 500 light dynamo to Messrs. Callender, McAustan and Troup, Providence, R. I. Their western agents, the Electrical Engineering Co., of Chicago, have just sold a 500 light dynamo to Underwood & Company, of Chicago.

WESTERN TRADE NOTES.

George Cutter, the electric specialist of the West, has just returned from a trip to Boston, where he arranged to act as Western agent for the Pettingell-Andrews Co. He will carry a full line of their K. W. cut-outs and rosettes, and also a good assortment of magnet wires. He has already received over six thousand of the incandescent lamps made by the Germania Electric Co., with which he expects to throw a light on his other good things.

Mr. C. B. Coon, the well known Chicago manager of the Hill Clutch Works, has just closed a large contract with the Valley City Street Railway Co., for the whole power transmission outfit, shafting, pulleys, rope sheaves, &c. The competition was keen, but Mr. Coon carried off the honors in spite of everything.

Wm. Baragwanath & Son, of West Division street, Chicago, are having built by the Hilles & Jones Co., some of their latest pattern heavy punching and shearing machines. They were compelled to contract for this machinery not only by the increase in their business, but by the general tendency to heavier and larger heaters in electrical and other branches. Where a few years since a 500 horse power heater was considered large, 800 to 1,500 are quite common now, and one turned out by the firm last year will heat to 216° F. the feed-water for 2,200 h. p. boilers.

Mr. Charles Jaeger, the manufacturer of mercury pumps for incandescent lamp work and delicate and intricate glass apparatus has removed from 200 E. Kinzie street, Chicago, to 48 Sand street, Brooklyn, N. Y.

Mr. Thomas G. Grier, managing engineer of the National Engineering Bureau, has recently been engaged in making investigations and tests of the various commercial incandescent lamps. He has made a study of this question and is well versed in lamp testing.

Mr. Geo. Cutter, the "electrical specialist" of the West, has recently issued a "novel" containing nine chapters of thrilling interest, which he, with true Western modesty, terms a "Folder," because it doubles you up. The peculiar feature of the production is that it reads backward and is, therefore, not in keeping with the progressiveness of Mr. Cutter. Among other interesting topics it deals with medicinal laboratory tests of Simplex wire, and in this connection we would suggest that the chloroform employed be administered to the trees along the circuit instead of to "Simplex," which has the reputation of amputating their limbs and being a mighty good "tree-cutter."

Mr. T. L. Townsend, representing the Partrick & Carter Co., is now in New Orleans and reports that the Partrick & Carter goods are very popular in the South. Mr. Townsend will come North via Memphis and St. Louis, ending his present trip in Canada about the middle of May.

NEW YORK TRADE NOTES.

The New Process Rawhide Co. was represented in town last week by Mr. T. W. Meachem, its president, who reports business very active, indeed, with every sign of its continuance. The demand is not only active for their electric railway rawhide gears but for their rawhide bound mallets, chisel-handles and other excellent specialties. Their gears are also now finding their way freely into machine shops.

The Werline Mfg. Co., of York, Pa., have just started up their foundry department and are now prepared to furnish tempered copper commutator bars and electrical castings of all kinds to the trade. The progress thus far made by this company is indicative of a brisk and successful business.

Mr. H. D. Wheatcroft, of the Independent Bung Co., of this city, left last week for Elizabeth, Wirt county, Va., where their mills are located, to make arrangements for the enlargement of their facilities for turning out electric light moldings, and also to make the final arrangements for making wooden cleats of all kinds and sizes, this being a new branch which has lately been added to their business.

The American Electric Exercise Machine Co., now located at 280 Broadway, this city, are making arrangements to move farther uptown. They will probably locate on 14th street, and take possession by the first of May.

The East River Lead Works, 523 east 19th street, this city make strip solder for electrical purposes, and the quantities which they sell to this industry is already enormous. They are supplying some of the largest concerns in the country.

The McCreary Electrical Specialty Co. of 18 Cortlandt street, this city, have completed arrangements whereby they are going to introduce the Almond Fexible bracket to the electrical trade, and have already secured numerous orders for this novelty. Their excellent small cut-out, which was described in The Electrical Engineer of Feb. 25th (in which their name was omitted in connection with it) is filling a long felt want, and their orders for it are becoming more numerous every day.

ST. LOUIS TRADE NOTES.

The St. Louis Car Company.—During the past five months, this company have built 318 cars, nearly all of which were for electric roads. With the additional buildings and machinery erected last year they now have a capacity for an output of 60 complete cars per month, but are compelled to work three hours overtime daily to keep pace with time orders. Their new combination elliptic and coil spring electric motor truck has been placed before their patrons and is meeting with excellent success wherever used. They have just finished 50 electric motor cars for the Davenport-Moline Railway Co. These cars are 16 feet long, elegantly upholstered seats and backs and finished in cherry and mahogany, with all modern improvements. They are now engaged on the following orders; 15 motor cars and 15 trail cars, for San Antonio, Texas; 25 34 ft. double truck cars for the Union Depot Railway Co., St. Louis; 6 motor cars and 6 trail cars for Windsor, Sandwich & Amherst Electric Railway Co.; 4 open motor cars for the Richmond City R. R. Co.; 2 motor cars for the Ft. Scott Rapid Transit Co.; 9 16 ft. cars for the Memphis Consolidated Street Railway Co.; 2 open motor cars for the National Electric Tramway and Lighting Co., Victoria, B. C.; 5 double truck 20 ft. motor cars for the Great Salt Lake and Hot Springs R. R. Co.; and 5 motor cars for the Davenport Central Railway Co.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XI. APRIL 22, 1891. No. 155.

THE DELANY CIRCUIT TRANSFER SYSTEM.

BY

Patrick B. Delany

THIS system has been designed to meet a comparatively new but promising demand for the use of private telephone and telegraph facilities, by subscribers whose business with their correspondents at distant points will not warrant the expense of a wire for their own use exclusively. The new system transfers a wire simultaneously at both ends from one pair of subscribers to another every five minutes, if desired.

It will be seen, in the accompanying diagram, that in the segment circles over which the trailing fingers travel, there are twelve segments, and reference to the controlling clocks, the trailing arms of which are mounted on the minute hand shafts, will show that the local circuits of the polarized switches are reversed at the end of each five minutes in the hour; therefore, the line is transferred from one segment to another every five minutes, and the apportionment of time among subscribers depends upon the disposal of the segments in the path of the trailing fingers.

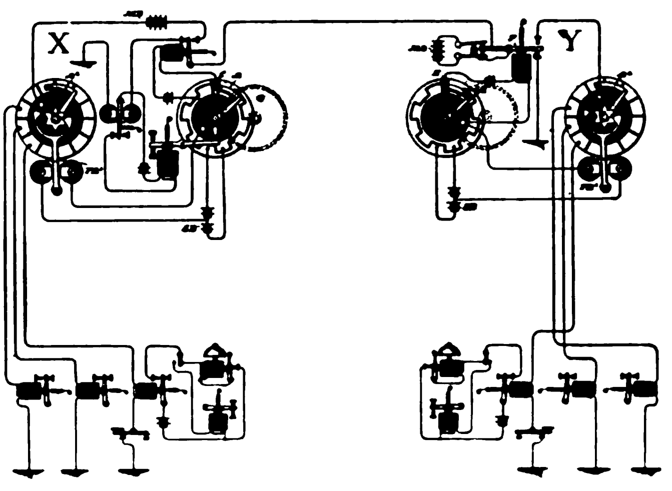
If a subscriber and his correspondent are connected to one segment they can communicate for five minutes each hour, paying the minimum fixed yearly rental for these facilities. Should they find that their business required ten minutes each hour, they could be connected to two adjoining segments, or, if preferred, to one segment on each side of the circle, which would enable them to communicate for five minutes every half hour. Other subscribers would have the line for whatever portion of time they arranged for, the object being to accommodate subscribers with whatever facilities they choose to pay for.

This class of business has not been encouraged to any great extent heretofore, because of the trouble and expense of making the transfer with uniformity and precision by hand. Now that the work may be done automatically, and with unerring reliability, there is no reason why a large subscriber business should not be secured, and at rates of rental which would, in the aggregate, amount to double the return from a wire rented exclusively to one party without making the rates to the individual subscriber burdensome. An important advantage of the system is the futility of the subscriber's disposition to cajole the switch into allowing him to have the circuit "just half a second longer." When his time is up he is unceremoniously cut off until the line comes round again. The arrival of the line is announced by an alarm bell, and the subscriber, knowing the arbitrary and unfeeling character of the automatic switchman, will naturally make the best use of his time.

The system covers several modifications of the plan shown in the illustration, which, however, is the preferred one, as the line circuit is not made up through any moving contacts, these being confined to the local circuits. The line contacts are always at rest, except at the instant of transfer, and are as perfect as though they were made through the ordinary switch.

The apparatus is regulated automatically every hour. If the clock at X gains or loses, not exceeding half a minute in the hour, an impulse will be sent from Y which will correct it, so that both clocks start off exactly on the second at the beginning of each hour. In practice, two ordinary clock movements will not vary more than a few seconds in an hour. By winding the clocks once a week, the switching system goes on night and day, requiring no further attention.

The connections in the diagram are interesting and easily followed. The main line is to earth at each end through the instrument of one subscriber or another. Main batteries M B are located at the central offices and looped into the line. Normally, the negative pole is to line at Y, and the positive pole at X. The drawing shows the apparatus setting itself at the end of the hour. The trailer, A at Y is on the thin blade E, which closes the local circuit of the pole changer F, the armature lever of which puts the positive pole of main battery M B to line. The trailer A^1 at X is on the small segment C which completes the local circuit of a neutral relay, the armature of which is connected to the line. When this armature lever goes to its front post the line is put to the polarized relay under it, and thence to earth. The tongue of this polarized relay is biased by a spring, but this bias is overcome by the positive current from Y, and the tongue is thrown to its left hand stop, where it closes the local circuit of the setting magnet. On the end of the armature lever of this magnet is a wedge-shaped piece which fits into the notch of the arm which forms a part of the trailing finger arm, and if the finger be fast or slow within the range of the relationship between the wedge and the notch, it will be set exactly at unison with the trailer A at Y. When this latter trailer passes off of the thin blade which represents three or four seconds, the local circuit of the pole changer is broken, the main battery is restored to its usual position, and the tongue of the polarized relay at X is drawn to its right hand stop by the spring, thus breaking the local circuit of the setting



THE DELANY CIRCUIT TRANSFER SYSTEM.

magnet, and releasing the trailing finger A. When this finger passes off of segment C, which takes thirty seconds, the local of the neutral relay is broken, the lever is drawn to its back stop, and the line connected to trailing finger A^1 at X, and to the subscriber connected to the first right hand segment at the top of the circle.

Two plates, each with six teeth lie in the path of the clock trailers A at X and A at Y. These plates are connected with the positive and negative poles of split local batteries S B so that when the trailing fingers pass from one segment or tooth to another, the local batteries S B are reversed and the tongues of polarized switches P R^1 are moved from one side of the trailing fingers A^1 A^1, which connected the line to the subscribers instruments, are moved from one segment to another every five minutes. One pair of subscribers is represented by a Morse outfit of relay, sounder and key—and an alarm bell. Normally the bell is switched into the local circuit of the sounder, so that when the line reaches the segment to which the subscriber is connected, the relay closes the bell circuit and notifies the subscriber that he has the line.

No temporary interruption to the line can disarrange the transferring apparatus. Should the line be broken, grounded or crossed, the clocks would go on, and the switches be operated just the same.

THE COLLINS DYNAMO.

The tendency in modern dynamo construction is decidedly towards a simplification of parts in the armature and field magnets. In the construction of alternating and multipolar continuous current machines especially, efforts are being made to reduce the energizing field magnets to their simplest form, and to dispense with a multiplicity of energizing coils. To that end recent constructors have adopted designs embodying a single magnet coil, energizing a number of pole pieces. The most recent form of this type is that due to Mr. W. Forman Collins, of Chicago, whose method will be readily understood from the accompanying engravings. As will be seen, the field magnet is confined entirely inside of a Gramme ring armature and consists of a single coil wound on a spool, the pole-pieces of which are extended radially across the head, and then again extended to form the working-poles which stand parallel to the axis of, and embracing the spool. In the multipolar machine the working-poles alternate with one another, forming a kind of cage, within which the spool is confined.

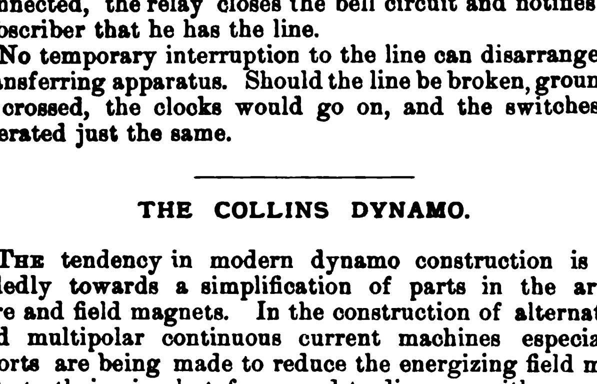


Fig. 1.—The Collins Dynamo.

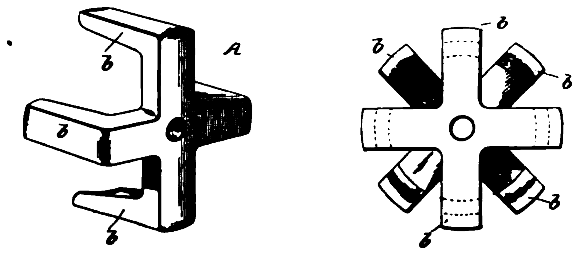
In the engravings, Fig. 2, shows one set of the pole-pieces of an eight-pole machine, and Fig. 3 the two sets of the pole-pieces together. The field magnet is composed of a core *a*, Fig. 1, wound with a single coil, and the extending pole-pieces, as shown.

In Fig. 1 the field magnet is shown keyed to the shaft, and, in consequence, rotates with it. The armature remains stationary, being maintained so by the spider C, which is fixed to one of the pillow-blocks. The commutator is loose upon the shaft, while the brush-holder is fixed upon the shaft so as to rotate with it. If the armature is to revolve, the spider is made separate from the pillow-block and connected to the shaft by a key (shown in dotted lines in Fig. 1); the opening through the core of the magnet is made large enough to allow the shaft to rotate freely, and the magnet is supported by making it a part of the frame of the machine.



Figs. 2 and 3.—Field Magnets of Collins Dynamo.

This form of field magnet may be used on the alternating current machine, in which case the number of pole-pieces is increased.

THE FLOW OF CURRENT THROUGH AN ELECTRIC ARC.

In a recent number of the *Repertorium der Physik* there is a paper by H. Luggin, which contains a minute descrip- of experiments made to determine the laws which govern the flow of current across an electric arc between carbon points. Referring to the anode, Luggin distinguishes two kinds of discharges, the one taking place from the crater with considerable current density, and the other from the surrounding rim with a smaller current density, and at lower temperature. The vertical variation of potential was investigated by means of test pencils inserted at different points. When the point of the test pencil (a carbon rod 1.3 millimetre diameter) was placed well within the crater, the mean potential difference between the luminous surface of the anode and the layer of hot gases immediately contiguous to it was found from a mean of five observations to be 33.7 volts. The corresponding value at the cathode was found from six observations as 8.78 volts, whereas Uppenborn had previously determined the potential differences as 32.5 and 5.2 volts. According to the author's estimate, that part of the potential differences between the electrodes, which is caused by the transition from the solid to the gaseous conductor, and is therefore independent of the length of arc, amounts to 42.5 volts, which is the sum of the values above given. The experiments were made with currents up to 20 amperes, and electrodes of sufficient size in each case to prevent the arc from hissing. A series of experiments was made to determine the hissing point, which the author found is reached when the current density exceeds about ½ ampere per square millimetre (3.23 amperes per square inch) of crater surface. For hissing arcs the potential difference between the anode surface and the layer of hot gases next to it is greater, but it does not increase in proportion with the current density, and it would therefore be incorrect to ascribe this potential difference to the existence of a constant resistance. Although this consideration would naturally lead to the assumption that the arc is the seat of a counter-electromotive force, the author has failed to detect the slightest polarization of the electrodes after the current was interrupted. By carefully contrived mechanism he was able to make connection between the electrodes and a delicate electrometer within the 0.005 part of a second after cutting off the current, and yet not a trace of charge could be detected in the electrometer needle. The author does not, therefore, believe it possible that the arc can be the seat of a counter-electromotive force of 40 volts, as suggested by Dub.

THE BUDA-PEST CONDUIT ELECTRIC RAILWAY.

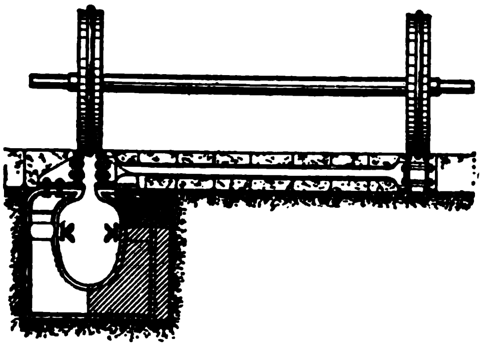


FIG. 1.—BUDA PEST ELECTRIC RAILWAY.

In a recent issue we made brief mention of the operation of the electric railway in Buda–Pest, in which a conduit system is employed and applied in a manner suggested some time ago in this country by Mr. Stephen D. Field. To the information already given we are able to add further details.[1]

As will be remembered, one of the wheels, Fig. 1, rests on a Haarmann rail, while the other rides upon the top of the conduit, which is built up of two angle irons, leaving a slot about 1⅝ inch wide. The conduit itself is oval in section, being about 11 inches wide and 13 inches deep. The cast iron frames to which the double rail is bolted are placed 48 inches apart. The conductors which are supported by insulators, consist of angle iron which has sufficient conductivity and is able to withstand the wear due to the friction of the contact plow. The motor employed, which is illustrated in Fig. 2, is constructed in a manner similar to the early Siemens dynamos with magnets of bar iron, which type was adopted in order to reduce as much as possible the weight of the machine. As will be noted, the motion is transmitted to the car axle through the medium of a sprocket chain. The E. M. F. employed is 300 volts.

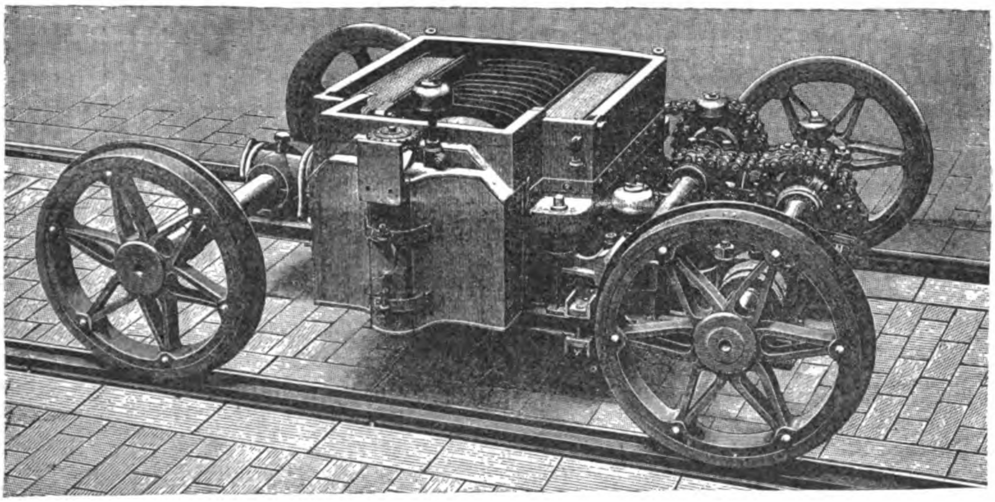

FIG. 2.—MOTOR TRUCK, BUDA PEST ELECTRIC RAILWAY.

At present there are three lines in operation in Buda-Pest, employing the conduit system; the first of these, started July 30, 1889, is a trifle over 1½ miles long, the heaviest grade is 15 per cent., and the sharpest curve has a radius of 155 feet. The second line is about 2¼ miles long, with the heaviest grade 16 per cent. combined with a curve of 140 feet radius. This line has been in operation since the 10th of September, 1889. The third line has been in operation since the 6th of March, 1890. In addition to these lines three more are in process of construction, and it is proposed to introduce the overhead system on at least one of them. During the operation of these roads the cars, up to the end of December, 1890, had covered 888,687 car kilometres, and carried 4,924,030 passengers, averaging 5$\frac{54}{100}$ passengers per car kilometre. The general speed of the cars within the city is limited to 9½ miles per hour, though beyond certain limits 11¼ miles is permitted; but in the narrower streets the speed is limited to 6, and at corners to 4 miles an hour. Each car makes 75 to 80 car miles per day of 16 hours.

THE ELECTRICAL PURIFICATION OF WINE.

FOR some time past, says *La Lumière Electrique*, M. de Meritens has been experimenting on the electrification of wine, and M. Martinotti on the application of electricity to vine diseases; and now F. Mengarini has just published a brochure extracted from the *Giornale delle Stagioni Sperimentali Agrari*, Vol. XVIII., entitled "The Reduction of Acetic Acid Present in Wine by Means of Nascent Hydrogen Generated by Electrolysis." If we take two jars filled with wine, connect them by a U tube filled with alcohol and divided at the middle by a parchment diaphragm, place platinum electrodes in the jars and pass a current, the acidity of the wine in the jar containing the kathode is diminished. It is this diminution of acidity due to hydrogenation that it has been sought to turn to practical account. The following are the results of some of the experiments. A 20.19 per cent. solution of acetic acid was converted into a 19.75 per cent. solution after four hours, and into a 16.72 per cent solution after 28 hours' electrolysis. Some sound red wine containing 7.208 per cent. of acid was exposed to the air for 24 hours, and turned sour when it contained 8.228 per cent. of acid. After eight hours of electrolysis the proportion of acid was reduced to 6.53 per cent. The current usually employed varied from 120 to 260 milliamperes, although currents of only 35 or 40 milliamperes were found to produce a beneficial effect. The apparatus intended for operations on a large scale is as follows:—A cylindrical vessel of 1 hectolitre (22 gallons) capacity, of enamelled earthenware, at the bottom of which rests a disc of compressed carbon 12 inches in diameter, which communicates with the negative pole by means of a carbon rod about ½ inch in diameter, encased in a glass tube containing paraffin. In the neck of the vessel slides a small earthenware cylinder, closed at the bottom by a sheet of parchment, on which rests a slab of carbon. The wine to be treated is poured into the larger vessel, the upper small cylinder containing alcohol and water.

EFFICIENCY TESTS.

BY

H. J. Williams

It is often desirable to obtain the efficiency of a dynamo or motor in cases where a suitable dynamometer for measuring the mechanical power is not available. That accurate results can be obtained, using only a voltmeter, ammeter and speed indicator, is well known to electrical engineers. But there are, doubtless, many to whom the problem seems difficult, if not impossible, and to them this article is addressed. The motor used in the following tests was of the consequent pole type, shunt wound for a potential of 110 volts and was rated at 3 h. p.

The method followed in calculating the efficiency is to measure the electrical energy absorbed by the motor, and subtracting the energy lost in the motor, to obtain the power available at the pulley. In a dynamo this loss should be added to the electrical energy developed in order to arrive at the power applied to the pulley. This loss consists of the wire loss in the armature and field coils, and the loss due to Foucault currents, hysteresis, and friction of the bearings, brushes, etc., to which must be added the loss of power in the rheostat, if the machine is running as a dynamo.

The wire loss is the product of the resistance by the square of the current flowing. Where the resistance is not known it may be computed by Ohm's law. Passing a current through the resistance, and measuring both the current and the drop of potential, we have at once, resistance equal potential, divided by current. In obtaining the armature resistances, we measure the current flowing through the armature, and the potential at the brushes. In this case, however, the armature must be fastened, so that it cannot revolve, or an error due to counter-electromotive force will be introduced.

We have now to account for loss due to Foucault currents, hysteresis and friction. These losses are generally considered together, although they could, if necessary, be separated. Once obtained, they may be considered practically constant for the same speed.

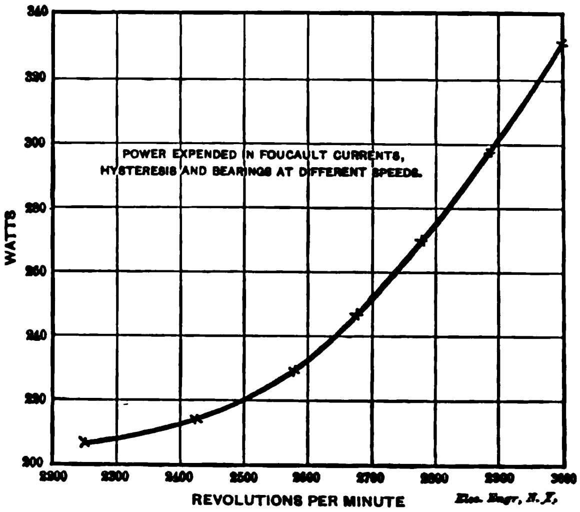
If now the belt is removed from the pulley, the motor is doing no work, and all the energy consumed is expended in wire loss and Foucault currents, hysteresis and friction. The wire loss is quickly calculated from the resistances and currents in the different parts, and the remainder charged to Foucault currents, hysteresis and friction.

Let us take an actual example. The potential at the mains is 112 volts; the total current flowing, with the belt removed, is 29 amperes; this gives us a total loss equal to 112 × 2.9 = 324.8 watts; the potential difference at the rheostat in the field circuit, 12.5 volts; the potential difference at the field terminals, 99.5 volts; speed, 2,250 rev. per min. By the method previously mentioned the resistance of the field was found to be 95 ohms, and that of the armature .29 ohm. The field current is $\frac{99.5}{95}$ = 1.047 ampere, and the loss in the field wire is 104.18 watts. As the rheostat is in series with the field, it has the same current, and the loss here is 13.09 watts. The armature current is 2.9 — 1.047 = 1.853 ampere, and the loss in the armature wire is .986 watt; making altogether 118.256 watts.

Now the total loss was 324.8 watts; having accounted for 118.256 watts as wire loss, the remaining 206.54 watts must be due to Foucault currents, hysteresis and friction. The resistance in the field circuit should be varied, and the loss due to Foucault currents, hysteresis and friction determined for each speed. The accompanying curve is thus plotted, showing the relation between these losses and the speeds at which they occur.

The belt was then replaced, and the motor loaded and the following readings taken: potential at mains, 112 volts; drop over field, 82 volts; main current, 25.3 amperes; speed, 2,500 rev. per min. The rheostat had not been removed from the field circuit when these readings were taken.

Now the field current is $\frac{82}{95}$ = .863 ampere, and the wire loss in the field is 70.77 watts. The drop over the rheostat must be 20 volts, and the loss here is therefore 17.26 watts. The armature current is 25.3 — .863 = 24.437 amperes, and the wire loss in the armature 59.55 watts. Looking at the curve we find the loss due to Foucault currents, hysteresis and friction for 2,510 rev. per min. is 220 watts. Adding these losses we have a total loss of 367.62 watts. The total power absorbed is 2,833.6 watts, giving 2,465.98 watts available at the pulley, or an efficiency of 87 per cent.



Curve of Efficiency at Various Speeds and Loads.

This method may also be applied to transformers, in which case the total loss consists of wire loss and loss due to Foucault currents and hysteresis, and the curve is plotted for the relation between the potential and the loss due to Foucault currents and hysteresis.

A WIRE-BOUND GODDESS OF LIBERTY.

During a performance in Laurenceburg, Ind., recently, in which the various industries of the town were represented by girls dressed in appropriate costume, the superintendent of the electric station produced a very pretty and novel effect. A young girl, dressed in white and the national colors, was wrapped in a network of wires, invisible from the audience, and twenty-five incandescent lamps were fastened in her dress and hair. One lamp rested on her head, and one was held in her hand as she stood in the attitude of the statue of Liberty. The house was darkened and the current turned on suddenly, producing a startling and beautiful tableau.

CENTRAL STATION MANAGEMENT AND FINANCE.—I.

(*Copyright, The Electrical Engineer.*)

BY

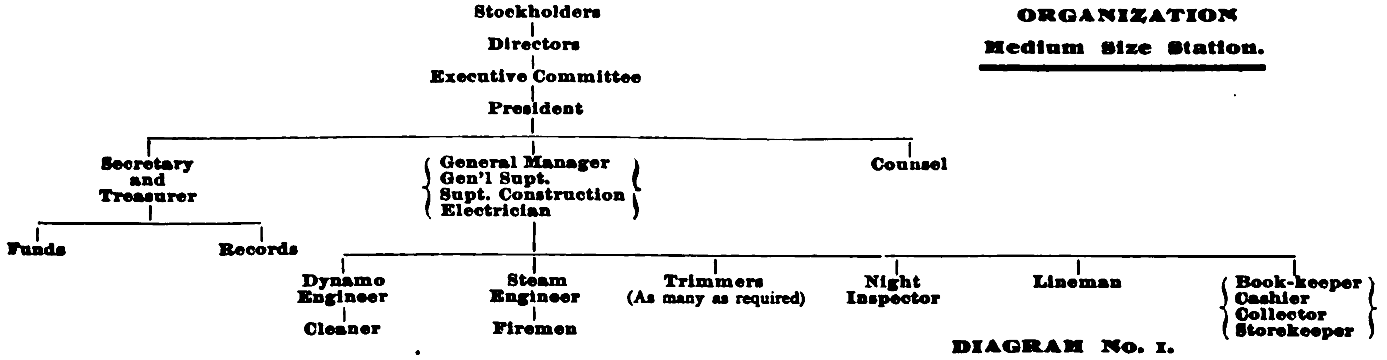
Horatio A. Foster

In the earlier days of electric lighting when prices ranged all the way from 70c. to $1.00 per arc lamp per night, and the incandescent lamp had but just started, central stations, which under ordinarily good management should have returned very large profits, were run in a most lavish manner as to expense, and too often on the contrary proved rank failures. This too, with machinery which has no very decided improvement to-day, and almost no change in the lamps used.

The central station business was so new that very few well established business men could be persuaded to take hold of its management, and it gradually fell into the hands of younger untried men, who too often were more prone to experiment with the business than to spend the necessary time in organizing it thoroughly on an economical basis. Again, the majority of those so placed had not the previous business experience to understand fully the necessity of systematic organization and strict discipline.

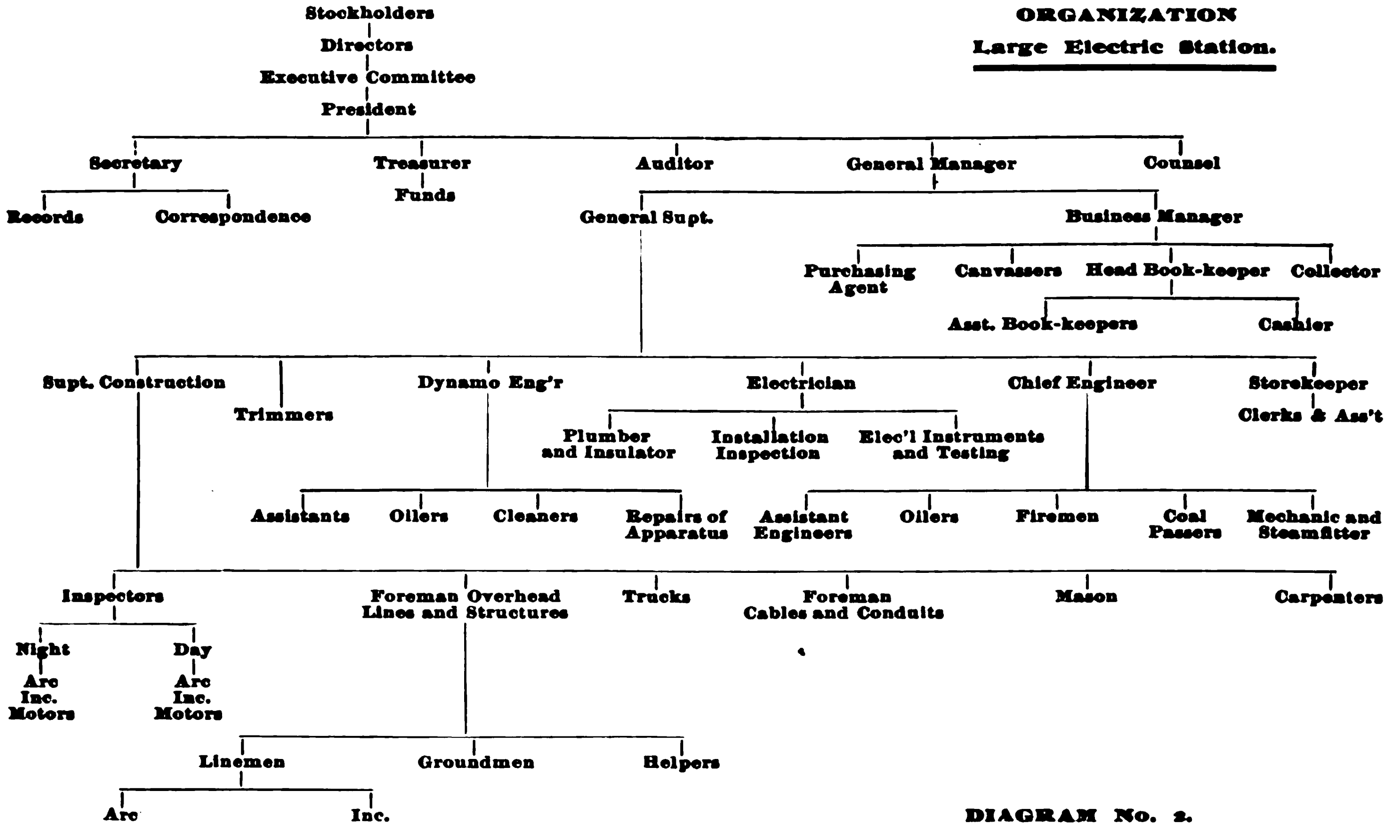
In the matter of labor, the various departments had not been gauged so as to determine what was a fair day's work and what would be the proper number of employees. Take the matter of carbon trimming alone; it was not so long ago that 40 lamps per day was considered the proper number for a man to clean and trim, when at the present time from 70 to 90 is considered a fair average; and in some places 100 is the standard, and stations have been known where 120 per man were crowded on. Other departments were similarly crowded, and many times men, recommended by some friendly official who had been influential in helping through city contracts, were given places when they were not needed. This, added to the extreme tenderness of the dynamo machine as then constructed, all helped to try the patience of the capitalist.

At the present time when prices have been pushed down to bed-rock by economically inclined Mayors and city officials, and sharp competition has set in, it is necessary to practice all the small economies which can only come from careful organization and strict discipline, and a most care.



ORGANIZATION
Medium Size Station.

DIAGRAM No. 1.



ORGANIZATION
Large Electric Station.

DIAGRAM No. 2.

Plans of Organization for Electric Light Stations.

ful system of accounts, both of financial and operating departments. To that end, the writer, together with the editors of this paper, has endeavored to outline a complete system of reports which shall embody all the points necessary to be kept in sight in order to show at any time the exact condition of any department, and, by recapitulation, to indicate the state of the business at regular periods, both financially and as to efficiency of operation.

The style of station taken as an example will be of that very large class which started originally with a small plant of arc lamps and gradually developed into large combined arc, incandescent and power stations. Circumstances will often govern the special method of organization; but the following has been found to meet the general requirements. For stations of the medium size, say 200 arcs and 1500 incandescents, Diagram No. 1. indicates a good scheme of organization. Larger stations, say from 600 to 2,000 arcs with from 5,000 to 20,000 incandescents would be better organized upon the plan of Diagram No. 2.

The organization naturally divides itself into the station or operating department, and office or financial department. As the latter is not materially different from any other counting room system we shall treat it with rather short mention, and that only at the end of the article.

All stations should be provided first, with a comfortable office for the officials, who necessarily have to be close at hand; and no man can be expected to make anything like accurate written reports without some place to do his writing. This should be provided for him in some convenient spot, generally under the eye of the superintendent or general foreman.

The next, and in the writer's opinion, the most important thing in the economy of the central station, is a well-constructed store-room, where everything of a portable nature, from office pens to cylinder oil, must be kept under lock and key, and only surrendered in quantities required by written orders from a foreman. The blanks necessary for use by the storekeeper will be referred to under the proper head.

Rule No. 1 and the most important regulation of all for the general superintendent, or any general foreman, is that no order for work of any nature be given other than in writing; this will be found to relieve all hands of responsibility by reason of bad memories, or otherwise; keeps a record of the time the order was given and finished, and the cost of executing the same. Blank No. 1, shown here slightly reduced, is a form which has been found to answer this purpose very well, and should be put up for use in books of 100 or 200 leaves.

The order number at the top must be placed on all requisitions for material from the store-room, and on all labor tickets used on the work indicated. When the job is finished and the slip is returned to the office, the value of all material recorded on the back, and of the labor shown on the labor tickets handed in under that order number, can be calculated and written in, and thus the cost of that particular job referred to at any time.

Where a system of this kind is adopted it is well to issue a few general orders, which should be framed or fastened permanently to some convenient bulletin and kept always in sight.

The orders would read somewhat as follows:

ORDER No. 1.

Issued.

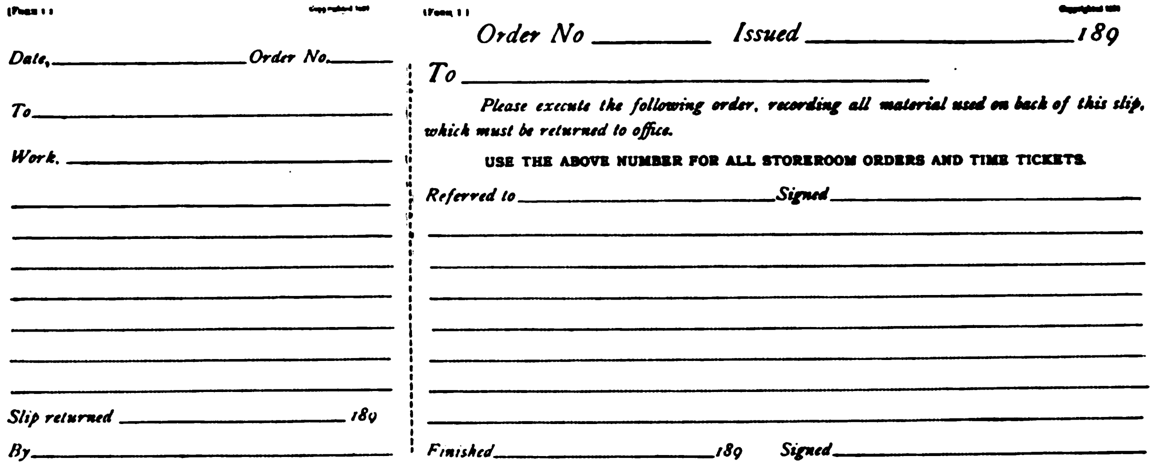
Signed.

All firemen or employees in the boiler room will put the above order number on their time tickets and store-room orders.

ORDER No. 2.

Signed.

All engineers or employees in the engine room will put the above order number on their time tickets and store-room orders.



Date, ______ *Order No.* ______

To ______

Work. ______

Slip returned ______ *189*

By ______

Order No ______ *Issued* ______ *189*

To ______

Please execute the following order, recording all material used on back of this slip, which must be returned to office.

USE THE ABOVE NUMBER FOR ALL STOREROOM ORDERS AND TIME TICKETS.

Referred to ______ *Signed* ______

Finished ______ *189* *Signed* ______

BLANK FORM OF DEPARTMENTAL ORDER.

And so on about as follows:

ORDER No. 3.

For Dynamo Room.

ORDER No. 4.

For Offices.

ORDER No. 5.

Repairs in Boiler Room.

ORDER No. 6.

Repairs on Engines.

ORDER No. 7.

Repairs on Electrical Apparatus.

ORDER No. 8.

Repairs on Pole Lines.

ORDER No. 9.

Repairs on Stations.

ORDER No. 10.

Repairs on Inside Wiring.

If motor work is done, or street car lines are run, additional orders can be issued to cover those departments.

In smaller stations it is perhaps unnecessary to make more than one order for general operating and one more for general repairs, although it is very convenient to know where the repairs were. Such orders will apply to all on the operating pay roll.

THE ACTION OF ELECTRIC CURRENTS ON THE HUMAN EYE.[1]

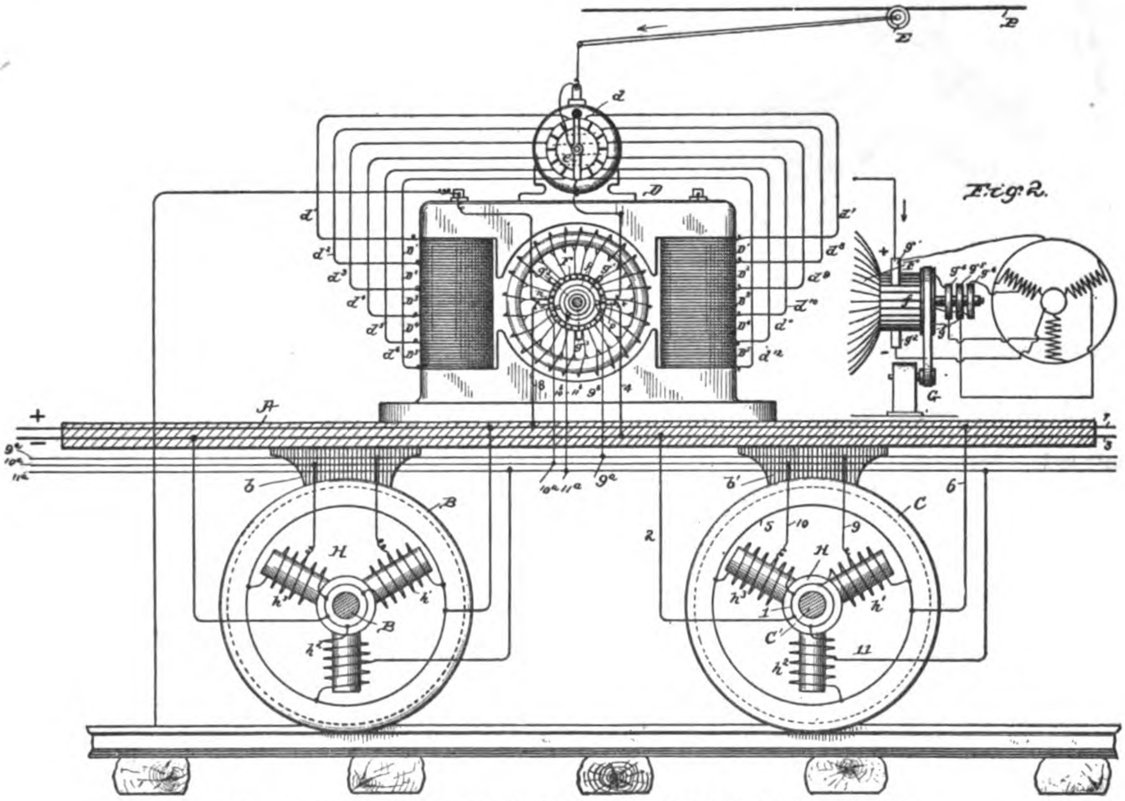
Prof. Dubois, of Berne, has been lately studying the physiological action of electric currents and discharges, and he has some interesting observations on the human eye, which, it is known, has luminous sensations under the action of galvanic currents. Sudden variations of current strength, especially at making and breaking the circuit, produce flashes. With a moistened plate at the nape of the neck, and a pad on the eye, a slight flash was distinctly perceived even with a Leclanché cell, giving about 1.20 volt and .04 milliampere. Raising the current to .5 milliampere, the observer could tell which pole was applied to the eye. On the other hand, the retina responds much less readily to discharges from condensers or induction coils. Not till a capacity of 0.037 microfarad and a pressure of 21 volts was reached, was a true retinal flash perceived; and not even with 10 microfarads were the durable sensations characteristic of the two poles produced.

VAN DEPOELE'S RECIPROCATING ELECTRIC RAILWAY MOTOR.

Our readers will remember the description of an electric power hammer in The Electrical Engineer of September 17, 1890, invented by Mr. Charles J. Van Depoele, of Lynn, Mass. The same reciprocating action of the bar of iron sliding in the solenoid, in connection with a current distributor has recently been applied by Mr. Van Depoele to motors for railway service. As will be seen in the accompanying engravings, Figs. 1 and 2, the machine is provided with sectional field magnet coils D^1, D^2, etc., connected by conductors d^1, d^2, etc., with separate sections of the commutator-switch d. This switch has a movable contact e, electrically connected through E with the conductor P. In addition to the main commutator brushes, P N, three equidistant brushes, g^1 g^2 g^3, are rotated about the periphery of the commutator by the small motor G. The speed of this motor is independently controlled, so that the rate of rotation of the brushes may be regulated as desired. In order to collect the current from these brushes, three insulated contact surfaces, g^4 g^5 g^6, are carried upon a sleeve on the armature shaft.

Upon the axles B′ C′ is mounted a triple reciprocating electric motor H, the magnetic pistons of which, moving within the actuating-coils are all three connected to a crank upon the axle by which the motors are carried.

Each one of the coils is in the form of a double solenoid, all the inner terminals of which are connected to a supply-conductor 1, connected to the positive brush of the machine by conductors, all the outer terminals of the coils being connected to a common return-conductor 5. This is connected to the negative brush of the machine and thence to the return conductor through conductors 6, 7, 8. The solenoids are therefore in multiple arc between the main brushes of the machine. The current is caused to rise and fall alternately in the motor engine coils by means of the triple moving brushes, one of which is electrically connected midway of each of the solenoids h^1 h^2 h^3 through conductors 9, 10, 11, which are connected with contacts engag-



Figs. 1 and 2.—Van Depoele's Reciprocating Railway Motor.

A FRENCH ELECTRICAL MINING PLANT.

The Compagnie Continentale Edison installed an electric haulage plant last year in the Mines de Marles, and it has given such satisfaction that the original plant is now about to be considerably enlarged. The generator is a 26 unit Edison machine, giving 400 volts at 900 revolutions. The pit is nearly 1,000 feet deep, and the line runs along a gallery 1¼ miles in length. The locomotive is 7ft. 8 in. long, 2 ft. 4 in. broad, 4 ft. 11 in. high, and weighs 2 tons, 6 cwt. The motor, a 10 unit machine, is arranged lengthwise and drives on to both axles through double helicoidal gearing. A speed of over 9 miles an hour is attained, and 10 b. h. p. is developed when hauling a train of 25 fully loaded skips, each weighing 14 cwt. The conductors in the gallery are two Vignole rails suspended from porcelain insulators fixed in the roof, and the current is taken off by traveling carriages fitted with brushes and connected to the locomotive by flexible conductors. The plant efficiency is stated to be 75 per cent.

---

[1] *Nature.*

ing the surfaces g^4 g^5 g^6. It follows, therefore, that as the three brushes g^1 g^2 g^3 and their contacts are moved about the commutator *f* they will successively approach and recede from the points of maximum and zero electromotive force, thereby causing a corresponding rise and fall of current in the motor coils of the triple engines in exact accordance with the movements of the brushes.

In Fig. 3 is shown a three-cylinder motor. The coils of the solenoids are inclosed in a continuous iron envelope *i*, which forms the outside casing and frame of the engine. Inside the coils k k^1 k^2 are placed diamagnetic tubes l l^1 l^2, which are securely fastened to the heavy rings O O^1 O^2 upon the outer ends of the cylinders, and to the casting D, which forms the central crank-chamber M, into which the plungers N N^1 N^2 are projected at the inner limit of their stroke. Upon the shaft S, is secured the crank K^3, upon the crank-pin of which are journaled the connecting-rods r r^1 r^2, which are pivoted to the plungers N N^1 N^2.

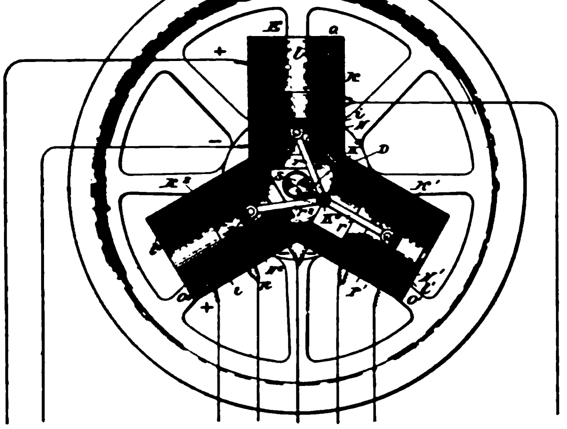


FIG. 3.—VAN DEPOELE'S RECIPROCATING RAILWAY MOTOR.

HYDROCHLORIC ACID IN BICHROMATE CELLS.

BY

Chas. Steinmetz.

WHEN small amounts of electric power are needed for closed-circuit work, as, for instance, for electro-plating, for medical use, etc., which cannot conveniently be derived from dynamos, the bichromate battery is generally called upon; that is, amalgamated zinc and carbon in a mixture of dilute sulphuric and chromic acid. This battery is used because it is simple and compact, combines high E. M. F. with low internal resistance, and has, for a single-liquid battery, a very low polarization.

Unfortunately, however, the usual bichromate cell has two great disadvantages. If too much sulphuric acid is used, then the internal resistance is low, and the E. M. F. high; but after a few minutes the liquid gets hot, begins to boil, the E. M. F. drops down, and, in spite of the best amalgamation, zinc and acid are consumed with frightful rapidity and the battery has to be taken apart at once. Or, if less sulphuric acid is used, crystals of the products of chemical action are formed on the zinc, the internal resistance increases greatly, and soon the current stops almost entirely.

A few days ago, in putting together my bichromate battery, I found myself short of sulphuric acid, and, remembering the suggestion made in one of the recent issues of THE ELECTRICAL ENGINEER, to use, instead of the usual compound, a mixture of bichromate, sulphuric acid and hydrochloric (muriatic) acid, I added a quantity of crude muriatic acid. The effect produced thereby seems to me remarkable enough to be of general interest. Only four cells were used, in multiple series. They were composed each of a thick arc-light carbon, and an amalgamated zinc rod of equal size. With a cold concentrated solution of bichromate of potash was mixed about as much sulphuric acid as necessary to set the chromic acid free, and then the rest of the hydrochloric acid added.

There were no instruments at hand to make exact readings; but from the work done by the battery I determined that, after over half a day's continuous use with a very low external resistance (cyanide of silver solution of large cross-section), neither the E. M. F. nor the internal resistance was perceptibly changed, and was about the same as in the ordinary bichromate cell with an equivalent surplus of sulphuric acid.

None of the four battery-cups got hot; neither could I perceive any boiling over, nor a formation of crystals on the zinc, but the battery ran steadily until the liquid showed the greenish-yellow color of approaching exhaustion. Only in one cup, where a smaller amount of hydrochloric acid was used, to see its effect, very few crystals were found on the zinc, but not enough to interfere with the working of the cell.

Therefore I can recommend all users of the bichromate cell to take only as much sulphuric acid as necessary for the dissociation of the bichromate of potash or bichromate of soda, and to add just about as much, or somewhat more, of hydrochloric acid. Even when the liquid shows signs of beginning exhaustion, it can be restored again, for a while. by a further addition of hydrochloric acid.

I need not remark that the name "chlorochromic acid" used in the notice referred to above, is wrong and misleading, because this chemical term means a chlorine-derivative of chromic acid, that is, the well-known chromyl-chloride, which is certainly not contained in the liquid, because it is dissociated by water into chromic acid and hydrochloric acid. The liquid contains nothing but a mixture of chromic, sulphuric and hydrochloric acid.

LAUNCH OF THE "ELECTRIC."

ON Tuesday, April 7, the electrically propelled pinnace "Electric" was launched from the Strand Electric Launch Works, Chiswick. This pinnace has been built by Messrs. Woodhouse and Rawson for the conveyance of troops between Her Majesty's dockyards at Chatham and Sheerness. The "Electric" has a tonnage of 4¾, is 48 ft. 6 in. long over all, by 8 ft. 9 in. beam, with an average draught of 2 ft. 3 in., her full complement being 40 fully-equipped soldiers. The battery consists of 70 Epstein cells, and the motor, which drives a two-bladed screw 22 in. in diameter, will develop 5½ b. h. p. at 750 revolutions. The anticipated speed is eight knots. It is the intention of the Royal Engineers to make some exhaustive trials with this type of boat.

FRANKFORT EXHIBITION.

IN order to show the application of electricity to aerial navigation, a captive balloon, capable of seating ten persons, will be exhibited by Captain Rodeck at the forthcoming Frankfort Exhibition. The pulley which controls the ascent and descent will be operated by an electric motor, and a telephone wire will enable conversation to be carried on between those in the balloon and the people at the starting point below. Experiments will be made with the view to the steering of the balloon by electricity, and in the filling of the balloon with electrically prepared water-gas. Messrs. Siemens and Halske will make the electrical apparatus.

PROFS. AYRTON AND PERRY'S STANDARD OF SELF INDUCTION.

As the intelligent study and design of apparatus involving the phenomena of self induction has proceeded, the necessity for some standard of self induction has become more and more apparent. This applies not only to dynamo electric apparatus such as alternating machines and converters or those employing pulsating continuous currents, but also that large class in which alternating or frequently interrupted currents of small volume are applied, such as are used in telephony and telegraphy.

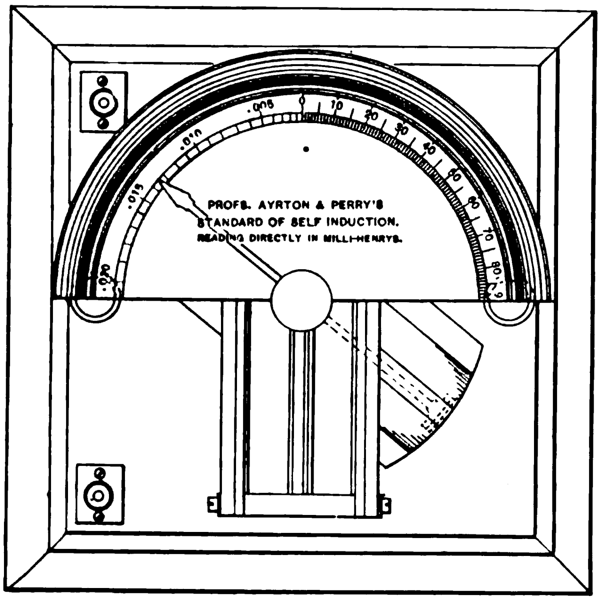

FIG. 1.—AYRTON AND PERRY'S STANDARD OF SELF INDUCTION.

It is evident that with some standard of self induction at hand, together with a secohmmeter and a Wheatstone bridge, the self induction of any apparatus can be quickly measured without much trouble or calculation.

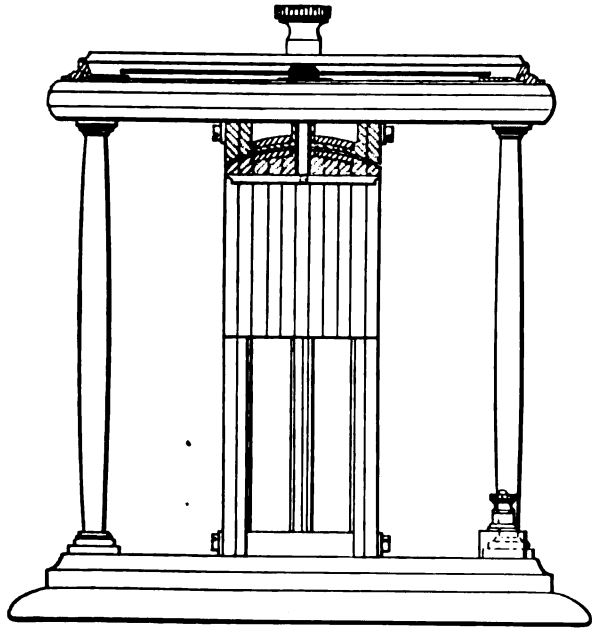

FIG. 2.—AYRTON AND PERRY'S STANDARD OF SELF INDUCTION.

Such a standard has been designed by Profs. Ayrton and Perry, and the instrument, as constructed by Messrs. Nalder Bros. & Co., of London, is shown in plan and side view in the accompanying engravings, Figs. 1 and 2.

The standard consists of three bobbins, two fixed and one movable, the latter so arranged as to be capable of moving through an angle of 180 degrees within the fixed ones. In order to get the maximum range and effect, the coils are wound upon a surface which is a zone of a sphere; this renders the use of two bobbins for the fixed coils a necessity. To get the maximum resistance to any change of form in the bobbins, they are built up most carefully with many pieces of the soundest Spanish mahogany.

This instrument in the stock form is wound so as to have self induction, varying from four millihenry's up to about thirty-six. The scale upon one side reads directly in millihenry's, and upon the other is provided with a degree scale, so as to be capable of use with a curve of calibration.

WIDTH OF SINGLE LEATHER BELTING.

BY

R. Grimshaw

THE following table, here published for the first time, gives the widths of 7/32 inch leather belting required to carry various horse powers at various speeds per minute; the belt being in good condition and wrapping half-way around cast iron pulleys, also in good condition. The tensions allowed for are such as to put no injurious strain on single leather lacings while permitting no slippage of the belt on the pulley.

The conditions and results are such as would be approved and desired by leather belting manufacturers for belts of their own make running in their own shops; in other words, where they wished, as consumers, to get the best life, drive, and money's worth out of the belts used.

WIDTHS OF SINGLE LEATHER BELT REQUIRED.

H.P.	Belt Speeds, Feet per Minute.								
	1,000	1,250	1,500	1,750	2,000	2,250	2,500	2,750	3,000

A NEAT TELEPHONE INDEX.

D. N. Coats, of Springfield, Mass., has just gotten up a device, that promises to be useful and not add to the vexations of telephone manipulations. The lists of subscribers are arranged in a portfolio which can be fixed against the wall, back of the instrument. A heavy cover holds the leaves in place, but can be dropped down or sprung back with a single movement of the hand. A metal guide slides along a bar across the top, controlling the indexed leaves. In looking for a telephone number one places the guide at the letter required, pulls down the cover and the leaves fall themselves, revealing the page wanted. The cover carries back the leaves automatically, when lifted, and holds them firmly in place once more. The index is made at the office of the Springfield Printing and Binding Company, and the pages can be renewed when enough numbers are changed to warrant printing a new list.

THE
ELECTRICAL ENGINEER.
[INCORPORATED.]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.
Telephone: 3860 Cortlandt. Cable Address: LENGINEER.

Geo. M. Phelps, President. F. R. Colvin, Treas. and Business Manager.

Edited by
T. Commerford Martin and Joseph Wetzler.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed*, Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

Vol. XI. NEW YORK, APRIL 22, 1891. No. 155.

The general mental qualification most necessary for scientific advancement is that which is usually denominated common sense.
—Joseph Henry.

THE MANAGEMENT OF CENTRAL STATIONS.

OCCASION was taken recently in these pages to review the report of the Massachusetts Gas and Electric Light Commissioners and to quote the statistics furnished therein as to the incomes and expenditures of the local companies. The information was not only valuable but much fuller than in any previous report, and we made, in passing, a mental note of the fact that the Commissioners made special reference to the great improvement in the methods adopted of keeping central station accounts. This improvement has kept step with that seen in central station construction, as evidenced by the valuable series of articles by Mr. A. C. Shaw that we have been publishing on modern New England stations.

It would, in truth, be difficult to dissociate the sound principles that apply to central station electrical engineering from those which apply to central station management and finance. A badly run station will owe its faults and failures to poor supervision and poor book-keeping in about equal proportion, while in a station that is properly conducted, the system of organization that is established in the dynamo room and engine room will run through to the last analysis of its accounts. It is needless to say that the hands of the superintendent and electrical engineer are immeasurably strengthened by the knowledge he enjoys of the manner in which his work is telling day by day in economy of operation and in the growing margin of profit.

With the object of assisting the many central station readers of The Electrical Engineer to a perfect plan of organization and a satisfactory basis of analysis and accounts, and carrying out a suggestion made to us some months ago by the president of a large parent company, we have begun in this issue a series of articles by Mr. Horatio A. Foster, who is well-known in electrical engineering and central station work, upon "Central Station Management and Finance." These articles will develop a practical plan applicable to the vast majority of stations in this country, and the advice and remarks of Mr. Foster will go to elucidate and explain many difficult points that come up in the conduct of a light and power plant. In order to make the plan adopted as simple and plain as possible, Mr. Foster has embodied in his text a large number of forms, blanks, sheets, registers, tickets, &c., such as are now actually in use by himself and others, and the regular employment of which adds so much to the efficiency and earning capacity of a plant. As to the advantages of each of these, Mr. Foster will have something pertinent and helpful to say, and we cannot but believe that the result of this endeavor will be seen in a higher standard of the art and industry.

WITH MORE ZEAL THAN DISCRETION.

An esteemed contemporary announces the discovery of three "weak points" in the patent laws of the United States. It has reached the conclusion that the establishment of "oppressive monopolies" under the protection of patents ought to be effectively prohibited; that the foreign inventor labors under almost insuperable disabilities in respect to the nature of proof required to establish his priority of invention in contested cases; and that patented inventions not put in public use within a reasonable time after the protection has been given, ought to be summarily deprived of it. We fear that the real source of our contemporary's disquietude is to be found in the fact that the American patent law has not been framed to meet the requirements of infringers. We may further remark that Congress appears to have no constitutional authority to change it to correspond more nearly to the views of this enterprising and industrious class of citizens. The Constitution of the United States, in express terms, empowers Congress "to promote the progress of science and the useful arts, by securing for limited times to authors and inventors, the exclusive right to their respective writings and discoveries." In view of the magnificent results achieved under its stimulus by the inventors of America, it is too late to question at this day, the wisdom of the fathers' provision; but whether wise or unwise, there it is, a part of our organic law, and likely to continue so. The patentee's right is *exclusive*, and though it may be limited in duration, it cannot be limited in scope. Congress has no power to step in between the patentee and his personal property, and undertake to dictate to him how, where and when he shall use it, or refrain from using it. We esteem it the one crowning merit of the American patent system, that the grant is unconditional and absolute, or without drawback or restriction in the nature of conditions subsequent. Two of our contemporary's points are therefore disposed by constitutional provision. As to the remaining one, it it is declared that while "it is already possible for American inventors to obtain valuable patent rights in foreign lands * * * * * * it is well-nigh impossible for a foreign inventor to secure a patent here if there can be found an American unscrupulous enough to claim the invention, naming a date prior to the foreigner's application in his own county." This is a gross mistatement of the provisions and practice of our patent law. Our rules of practice provide that he who, being an original inventor, first makes known to others within the realm (thus enabling its existence to be legally proven), the invention he has made, and perfects and seeks to patent the same with reasonable diligence, is entitled to the grant. It matters not in the least whether he be a foreigner or a native; the rule is the same. The benefit to the public, which is the consideration, and the sole consideration, for the grant, arises from the making known of the invention to the people of the United States. There is no conceivable reason why we should reward a foreigner, as of a matter of right, for something he has done in his own country and not elsewhere, unless he has, by publication or otherwise, constructively placed some person in this country in possession of a knowledge of it, and the very moment he has done this, he stands precisely on the same footing, in every particular, with his domestic competitor.

Suppose it is true that a certain proportion of the patents granted are never put to use. Suppose that some "successful" inventor has "found that progress along a certain line was barred by some old claim that has never been put to any service whatever, and neither benefits the public itself or permits any one else to do so." How large is the proportion? There are now in force about 300,000 patents. How many of these are obstructions in the way of progress because their owners will neither use nor permit them to be used? Not one-tenth of one per cent. Is it then worth while in attempting to guard against a limited and largely imaginary evil, not only to inflict incalculable injury and injustice upon the vast body of deserving inventors, but, by removing what is the principal incentive and stimulus to invention, the absolute security for a fixed term of years of patented property, to dry up, as it were, the spring of invention at its very source?

DELANY'S LINE TRANSFER SYSTEM.

ONE of the most noted developments of modern telegraphy is unquestionably that which is exhibited by the increase in the number of private lines that connect the offices of firms situated in different cities. These private lines, sometimes extending for hundreds, and even thousands of miles, have become a source of considerable income to the telegraph companies; and now the excellent work and service furnished by the Long Distance Telephone Company will, no doubt, see a large extension of this service, not only for telegraphic, but for telephonic purposes. The necessarily high cost of such a service makes it desirable to devise some means by which firms may enjoy its benefits without too serious a drain upon their resources, and hence a system by which the line can be "distributed" to a number of subscribers in succession during a fractional part of each hour must, we are convinced, prove of considerable value. It is true that this could be accomplished mechanically by an operator situated at the central office, but an automatic transfer of this nature will not only prove more economical to the company owning the lines, but will avoid all disputes as to time. Mr. P. B. Delany's system, which he describes in another column, seems well calculated to afford a proper system of transferring lines from one subscriber to another, and may, we hope, soon be seen applied in a practical way.

EFFICIENCY TESTS.

EVERY intelligent user of power is desirous of knowing the exact economy of the prime mover which drives his machinery. In the case of the steam engine, the indicator enables him to ascertain this point with tolerable accuracy and without any practical inconvenience. The user of electric power who is desirous of obtaining information as to the efficiency of his plant, and especially of the motor itself, is frequently prevented from ascertaining these facts by the supposition that a dynamometer is required for his purpose. But what the indicator is to the steam engine, the ammeter and voltmeter are to the electric motor, and by the aid of these and a few simple calculations, considerable accuracy can be obtained in testing electric motors, even without the use of the dynamometer. A simple method of applying these universal instruments is described in our columns this week, by Mr. Williams, and will, we hope, be applied by power users.

INCANDESCENT LAMP EFFICIENCY.

THE recent large reduction in the price of incandescent lamps has had the natural effect of again drawing attention to an important subject involving in the highest degree the success of the central incandescent lighting station. A simple analysis had early shown that certain relations existed by which the greatest economy in the operating expenses of the station could be ascertained, these conditions involving primarily the cost of the lamp and the cost of power; and in 1888 Mr. John W. Howell, in an admirable paper read before the American Institute of Electrical Engineers showed that between very wide limits of operation the greatest economy was obtainable when the cost of lamp renewals amounted to about 15 per cent. of the total operating expenses.

It was pointed out in our last issue by Mr. H. Ward Leonard, and is now shown by Mr. Thos. G. Grier, in his paper read before the Chicago Electric Club, that the reduced price of the lamp permits it to be run at a higher efficiency, and though the renewals are more frequent the total cost of operation is reduced. It seems difficult to understand these arguments readily, but their truth must sooner or later force itself upon general recognition.

A Standard of Self Induction.

WITH the advent of dynamo electric machinery, and more particularly of alternating apparatus came the necessity for exact methods of measurement of self and mutual induction, and among the workers in this field, who have earned the gratitude of all electricians, are Professors Ayrton and Perry. Their secohm-meter was a large step in advance, placing the measurement of inductance on an accurate basis, and this, together with the standard of self induction, which we describe in another column, will go far towards removing the calculation and design of many forms of apparatus from the realm of guess-work to that of intelligent predetermination.

THE EVANS HYDRAULIC CAR GEAR.

AMONG the large number of methods and devices applied to, or suggested for, transmitting the power of the motor armature to the axles of electric street cars, is one in which a liquid is applied as the medium of transmission. This method possesses the qualities of smooth action and great regularity, while at the same time it possesses the important advantage that it permits the motor to be operated continuously at its best speed, and hence with the highest electrical economy.

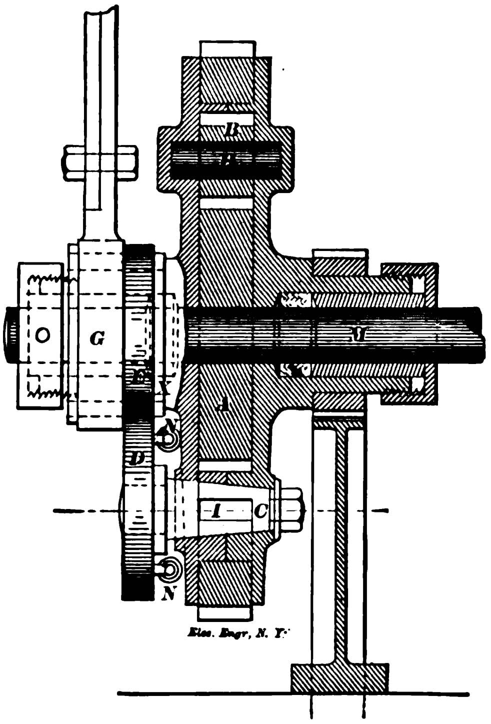

FIG. 1.—EVANS' HYDRAULIC CAR GEAR.

In applying this method to railway work, Mr. Geo. F. Evans, the inventor of the well-known Evans friction cone driving for dynamos, has designed the hydraulic gear illustrated in the accompanying engravings. As will be seen, A is a gear keyed fast on the shaft, M, which is kept in continuous revolution. The gear B being loose upon the stud, H, is free to revolve unless it is prevented by the flow of the oil through the channel, I, being cut off by closing the valve, C. This combination is arranged with a clamp, G, which grasps the loose sleeve, E, engaging the gear, D, and, when the pressure is sufficient, it closes the valve, C, automatically, for the purpose of cutting off the flow of the oil through channel I.

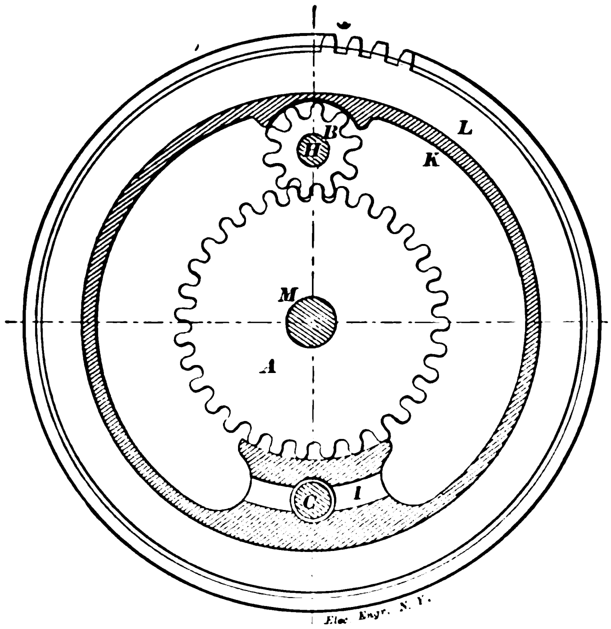

FIG. 2.—EVANS' HYDRAULIC CAR GEAR.

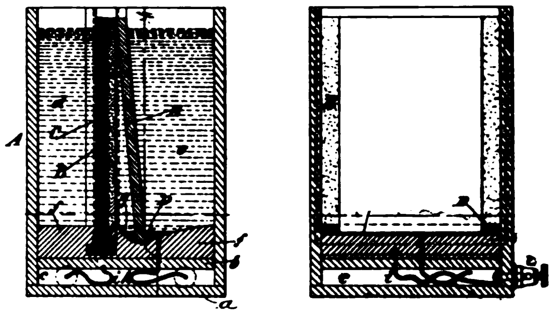
The gear L, which is clamped in place by the housing, K, must revolve because one chamber has been pumped full of liquid, and it will continue to run at the same speed as gear A until the pressure is released on clamp G to such an extent that the springs N N will force the valve C open, thus releasing the confined oil. Gear L will then stop, and the oil will continue to flow until the valve C is closed again for the purpose of starting gear L. With this arrangement any speed can be obtained and maintained, the combination acting equally well in either direction.

THE CROWDUS BATTERY.

WHEN connections between battery cells are made, as is customary, at the top of the cells, the charging with exciting fluid is often troublesome, and is liable to disarrange the connections. To overcome this objection, Mr. Walter A. Crowdus, of Memphis, Tenn., has invented a method by which the connections are made through the bottom of the cell to terminals on the exterior at one side or at the ends.



FIGS. 1 AND 2—THE CROWDUS PRIMARY BATTERY.

The accompanying engravings Figs. 1 and 2 illustrate the construction of the cell. The latter has a removable bottom *a* and a false bottom *b*, leaving the space *c* between them for the wire connections. Above the false bottom is a porous partition B dividing the cell into the two chambers *d* and *e*, in the former of which is the electrolyte for the negative plate, and in the latter, that for the positive.

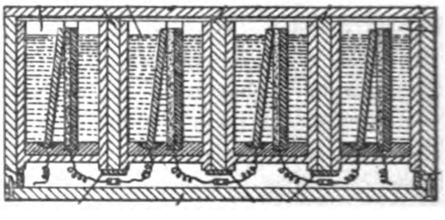


FIG. 3.—THE CROWDUS PRIMARY BATTERY.

The negative electrode C consists of a plate of porous carbon placed close to the partition, so as to assist the latter in preventing the mixing of the electrolytes, while the positive electrode, E, stands with its lower edge in a mercury bath D. The sides of both plates rest in grooves in the walls of the cell, and are held in place by a filling of wax. A wax coating is also applied to the bottom of the cell, extending under the plates as shown at *f*. The mercury trough is formed of metal and placed at the lowest point of the chamber, as shown at *g*, Fig. 1. The connecting wire *h* is soldered to the trough and drawn down through the false bottom.

The wire *i* similarly connects with the bottom of the negative plate by passing through the bottom *b*. If the plate be of carbon, its lower edge is electroplated with copper. A bar of metal is then soldered to one side of this copper rim and the wire *i* embedded in, or soldered to the bar. The wires *h* and *i* are carried through the bottom space to either side of the cell, and pass out through holes for connection with binding-posts, as shown in Fig. 2. The bottom *a* is made removable, so that the connections can be properly arranged before it is fastened on. This is the construction for single cells.

For batteries containing a number of cells connected in series as shown in Fig. 3, the cells are constructed without the bottom *a* and are arranged in a case, the wire of one cell being connected to the wire of the next at the bottom of the case.

Literature.

Hints to Power Users. By Robert Grimshaw, M. E., New York, 1891. *Cassell Publishing Co.* 6½x4¼, 160 pp. Cloth. Price, $1.

THIS is a quaint little book, written with all Mr. Grimshaw's well known force and piquancy of style. It is a series of thoughts and observations on the various questions that come up for settlement by power users, and it puts the pros and cons very clearly and effectively. The remarks, for instance, on the desirability of get-at-able boilers and on the merits of big fly wheels are pointed and pithy; and it is just such reflections as these that will help a superintendent to save many a dollar. The work discusses in this shrewd, commonsense manner about 900 different subjects, and while on some of them so little is said as to make one wish for more, it is impossible not to derive benefit and instruction from every single page. The form of the book is handy, enabling it to be slipped into the pocket; the type is large, and the index is admirable.

Aerial Navigation. By O. Chanute, C. E.: *Railroad and Engineering Journal.* N. Y. 1891. Paper, 36 pp. Price, 25 cents.

This pamphlet contains a most interesting lecture delivered by Mr. Chanute before the students at Cornell. It is a fitting resume of the work done up to the present time in the navigation of the ambient air. Mr. Chanute inclines to the opinion that great results cannot be expected of balloons, which have reached a speed of 14 miles an hour and even now could make 25 or more. Besides, balloons are unwieldy, and as they grow in size becomes unmanageable. Much greater speeds, he says, can perhaps be attained eventually with aeroplanes, imitating the action of flight, and dispensing entirely with the gas bag.

The question of the motive power is vital, and Mr. Chanute gives the results obtained with electricity by the Tissandiers, and by Renard and Krebs. Assuming that the weight of 50 lbs. per h. p. is all that could be allowed in successful aerial navigation, he shows that primary batteries and storage are alike, still too heavy. Renard's primary battery weighed 66 lbs. per h. p. per hour, to which must be added the motor, weighing, if of the Trouvé make, 26 lbs. per h. p. with accumulators. The combined weight of cells and motor ran up to 130 lbs. per h. p. Mr. Chanute gives M. Trouvé credit for a small motor of aluminum, weighing only 7.7 lbs. per h. p., and adds that he is now building one for the Portuguese Government that is of 10 h. p. capacity and weighs only 220 lbs. The 7½ lb. motor strikes us as rather visionary, and we find no reference to it in the life of Trouvé recently issued.

We recommend this little pamphlet cordially to our inventive readers. It is full of data and highly suggestive.

PERIODICALS.

IN the March and April numbers of the *New England Magazine*, George H. Stockbridge has two illustrated articles, entitled respectively "The Early" and "The Later History of Electricity in America." While it might perhaps be truthfully affirmed that Mr. Stockbridge has given rather a history of the electricians than of electricity, yet the best part of his work by far is not the history at all, but rather his appreciative, and in the main just estimate of the relative importance of the contributions of different inventors and discoverers to the magnificent results which the world is just beginning to realize. He deals mainly with the work of Franklin, Henry, Morse, Vail, Page, Farmer, Davenport, Thomson, Edison and Weston, with necessarily brief reference to many others. Although Mr. Stockbridge has not undertaken to add to the historical or biographical material in our possession, he has marshalled familiar facts in a way which at times, gives them a new and important significance. The author's sense of historical perspective is excellent, but his work is unfortunately marred by many minor inaccuracies of statement, which a little care might easily have avoided. For example, he locates Morse's original experiments at Columbia College instead of the University; he gives us the International telegraphic code in place of the one devised by Vail, known and used all over America as the "Morse code;" he tells us that Edison "employed Hughes' discoveries regarding certain qualities of carbon to the production of the Edison telephonic transmitter," the fact being that Hughes' discovery, although unquestionably of independent originality, was not known in America until nearly two months after Edison's carbon telephone had been successfully used in conversation between New York and Philadelphia. Nor can the implied assertion be admitted that the duplex telegraph of Joseph B. Stearns owes anything to Edison, or the quadruplex telegraph of Edison anything to Dr. H. C. Nicholson of Kentucky. We mention these instances because some of them are liable to perpetuate historical error in matters not wholly unimportant, and because it is by his accuracy in small things that a censorious world is prone to pass judjment upon the reliability of a historian. An article descriptive of the Thomson-Houston factory at Lynn is promised for the next number of the *New England*.

BOOKS RECEIVED.

Histoire d' un Inventeur. Exposé des Descouvertes et des Travaux de Gustave Trouvé dans le Domaine de l' Electricité. By Georges Barral. Paris: 1891. *Georges Carré.* Paper; 610 pp.; 6½x10 in. Illustrated.

Die Elektrischen Verbrauchsmesser. By Etienne de Fodor. Vienna: 1891. *A. Hartleben.* Paper; 219 pp.; 5x7 in. Illustrated. Price, $1.25.

Die Glühlampe. Ihre Herstellung und Anwendung in der Praxis. By J. Zacharias. Vienna: 1891. *A. Hartleben.* Paper; 195 pp.; 5x7 in. Illustrated. Price, $1.25.

Die Zeittelegraphen und die Elektrischen Uhren vom Praktischen Standpunkt. By Ladislaus Fiedler. Vienna: 1891. *A. Hartleben.* Paper; 207 pp.; 5x7 in. Illustrated. Price, $1.25.

THE LARGEST ELECTRIC MINING PLANT IN THE WORLD.

The Cœur d' Alene Silver-Lead Mining Company have contracted with the Edison General Electric company for an electric power transmission plant, to operate all the machinery and furnish light for their mill and mine at Burke, Idaho. The plant consists of two 225 horse-power Edison generators, to be located about one and one-half miles from the mill, and driven by water power from the falls of Canyon Creek, using Pelton wheels under about 690 feet head. The mill machinery will be driven by an 80 horse-power motor belted direct to the main shaft of the mill. The Ingersoll steam drill compressor now in use will be operated by a 60 horse-power motor belted to the fly wheels of the compressor. The Lidgerwood steam hoist now being used will be operated by a 50 horse-power motor geared direct to the present driving shaft. The pump, located on the 500 foot level will be driven by an 80 horse-power motor geared direct.

The entire plant is at present being operated by steam, and the application of electricity will be so arranged that all the machinery, or any portion of it, can be operated by either steam or electric power at any time. The entire electric plant will make about eight car loads, and will probably be the most extensive electric mining plant in the world. The contract was made through Mr. S. Z. Mitchell, Edison District Agent, at Portland, Ore.

ELECTRIC LIGHT IN THE SUEZ CANAL.

Thanks mainly to the electric light, the average time of transit through the Suez Canal goes on diminishing steadily from year to year. Last year it was 24 hours 6 minutes, whereas in 1889 it was 25 hours 50 minutes; in 1888, 31 hours 15 minutes; in 1887, 33 hours 58 minutes, and in 1886 not less than 36 hours. In the preceding year the average time for the transit of vessels traveling at night with electric light was 22 hours 30 minutes, and in 1890 it has reached the short and quick passage of 22 hours 9 minutes. The shortest passage through the canal by a steamer using electric light was made last year. The time was 14 hours 15 minutes, or as much as 30 minutes faster than the fastest in 1889.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER *150 Broadway, New York city.*

DISCUSSION OF THE PHENOMENA OF CURRENTS OF HIGH FREQUENCY.

It is not from any desire to have the last word that I have answered Mr. Tesla's statements as they appeared; it has simply been to correct misunderstandings. In regard to the experiment which I mention, as performed by immersing in water a lamp bulb in which a single strip of carbon had been mounted and connecting the water and the filament to a source of high potential alternating current at high frequency, and whereby the strip of carbon was brought to bright incandescence, I simply said that conduction through the glass could not have had any effect in this experiment. I made no general denial that a slight conduction occurred with even the best dielectrics. The glass in my experiment being immersed in water, the assumption of high temperature which Mr. Tesla makes as increasing the conductivity of the glass, is not to be considered in this case. The glass was only heating where it was not so immersed, and where, therefore, no connection with the circuit existed.

Mr. Tesla bases a long statement about dielectrics, insulation, resistance, perfect conductors, degrees of conductivity, etc., on the statement I made in relation to the experiment and the phenomenon it presented; and he even asks whether I have "then never measured insulation resistance" and "by a conduction current." Similar irrelevant questions follow this typical one. I have said that "if conduction through the glass were a possibility (in the experiment and accounted for the phenomenon presented) this action (of charging a lamp bulb as a Leyden jar and receiving a charge therefrom,) could not occur." Mr. Tesla does me the injustice of applying a statement which related to a particular experiment and phenomenon to classes and conditions of phenomena which any one at all familiar with the circumstances would rule out. Mr. Tesla says: "My statement that conduction is concerned to some, *though perhaps negligible,* extent in the experiment above described was, however, made not only on account of the fact that all bodies conduct more or less, but principally on account of the *heating of the glass* during the experiment." The italics are mine. In the experiment the glass was immersed in cold water, and only that portion not immersed and not in contact with the current conductor or the surrounding water, was warmed. This disposes of the paragraph of contentions of Mr. Tesla based on heated glass in the experiment.

In regard to the estimate of the number of complete waves of sound corresponding to a given number of alternations, I freely confess that I was in error, and that the number given by Mr. Tesla is correct. The number of complete sound waves does, as Mr. Tesla points out, correspond to the number of alternations, as the expansion and the contraction of the arc stream, corresponding to wave condensation and rarefaction, occurs with each alternation. This is a point which I had missed in the former consideration of the matter, but, of course, if the limit of audition is above any of the rates considered, it would not affect the argument except as it relates to the degree of approximation to that limit.

Without calling upon Mr. Tesla to state how far "Earth is from Heaven" in his view, I will simply state that my experiment of five or six years ago, which called forth his remark, certainly did teach me something then, and added somewhat to my information in certain directions.

I was perfectly well aware of the effects of self-induction, including impedance, pointed out by Mr. Tesla, when I spoke of the insertion of a coil of large self-induction into a circuit of arc lights as steadying the current and lessening its undulations. In regard to the effects of self-induction I may state that the property of impedance I have always regarded as one of those effects.

It is not true, as stated by Mr. Tesla, that self-induction "renders the undulations more pronounced." Whether it will do so or not depends on the shape of the wave of undulation. Not all shapes of wave have the greatest rate of change when the current has a small value. What is true is that [illegible] of a sine curve would not be true of a sawtooth wave. [illegible] was the effect of a large self-induction [illegible] the current was of a fluctuating character. [illegible] may be considered in this case as made up of a steady current of average current value, [illegible] which has been superimposed an alternating current value, or it may be considered as made up of a steady current of less than the average value with a pulsating current of small value superimposed. These assumptions, to be exact, of course, are made on the basis that in the fluctuations the strength of the current does not change very greatly, or that the minimum current and the maximum current values are not far removed from the average value. Now the effect of self-induction introduced into such a circuit with arc lights is, by its impedance, to diminish the value of that portion of the current which is, so to speak, alternating or fluctuating; and whether the waves of alternating or pulsating currents, so greatly diminished in amplitude, will be sharpened or smoothed out by self-induction will depend upon their original form. It is the effect of self-induction in producing impedance, and therefore restricting the value of the fluctuating or alternating current strength, superimposed on the much larger constant or steady current, to which I referred in speaking of the smoothing action. Mr. Tesla was right in his general statements of principle, but wrong in his application of them to the case in point. He was not right, however, in separating the effect of impedance from self-induction in the case under discussion.

I have no desire to prolong this discussion and will leave out of consideration any reference to effects on clutch or clockwork lamps, or to the physiological effects of currents. I have in the above comments confined myself strictly to those matters which it seemed necessary to have cleared up in some way. I hope that in stating my position in relation to the matter I have made myself clear so as to avoid further misunderstandings.

ELIHU THOMSON.

LYNN, MASS.

IMMERSING CONVERTERS IN OIL.

I have read a recent article by C. E. L. Brown on the "Uses of Oil in Insulators and Transformers." Mr. Brown states: "The application of oil as insulating material for transformers carrying a very high potential was first proposed by me," meaning Mr. Brown himself. In your journal of April 15th, Prof. Elihu Thompson writes: "It may be interesting to your readers to learn that the use of oil in converters, was the subject of a patent applied for by me on May 9th, 1887, or about four years ago, the number of the U. S. Patent being No. 428,648."

I received a patent dated Oct. 25, 1878, No. 210,987, in which the following claim was allowed: "The within-described method of insulating induction coils or bobbins of wire of electrical instruments, that is to say, by immersing said bobbins or coils in a liquid insulating substance, as set forth."

Professor Thomson's patent is titled "A casing for induction coils," and although in his specifications he speaks of the value of oil, in his claims he steers very clear of that one claim of mine. He has six claims all commencing with the words "A combination" of different things, but having little or no reference to the fundamental principle of oil being used in induction coils or converters or transformers. He doesn't make use of the words "converters" or "transformers."

DAVID BROOKS.

PHILADELPHIA, PA., April 17, 1891.

ELECTRICAL ENTERPRISE IN MANITOBA.

Mr. W. Bathgate, of the Manitoba Gas and Electric Light Company, recently invited the members of the city council to the works of the company in Winnipeg.

The boiler house is [illegible] feet long by 40 feet wide. There are nine steel boilers of [illegible] h. p. One hundred pounds of steam is carried. The smokestack is [illegible] feet high, and five feet in diameter. The engine and dynamo house is 50 feet square and contains two pairs of compound surface condensing Brown automatic engines of 300 and 400 h. p. respectively. The driving wheel of the 400 h. p. engine weighs 26½ tons, and is 18 feet in diameter and [illegible] inches face, and drives the largest belt that has been made in Canada—three ply 3 feet 4 inches wide and 85 feet long. The shafting with which it is connected is fitted up with friction clutch pulleys made by the Vulcan Iron Company, from which are run two Thomson-Houston arc machines for city lighting and one 1,000-light incandescent dynamo, with space for two more large incandescent dynamos. Three incandescent dynamos of 2,000 light capacity are run from the shafting, driven by the 200 h. p. engine as well as the arc dynamos which are used for private lighting. The total capacity of arc plant is 135 lights, 2,000 c. p.; the total capacity of incandescent plant is 3,000 lights, 16 c. p., with capacity for two more incandescent machines of 2,500 lights to be installed this fall. The pumps in connection with each engine consist of one Blake air pump, one circulating pump, one [illegible] boiler feed pump, and one large Northey auxiliary pump fitted up with [illegible] feet of 3-inch hose for fire protection purposes [illegible] steam. The workshop contains a 7 h. p. Otto gas engine furnishing power for blacksmith and machinery shops, which are fitted with two lathes, one 15 foot and one 14 foot bed, screw cutting machines, emery wheel, grindstone, drills and punching machines, all the necessary repairs for both gas and electricity being done in these shops.

Reports of Companies.

MEXICAN TELEPHONE COMPANY.

The Mexican Telephone Company, at its annual meeting in New York, on April 15, elected the following directors :—President, Robert Colgate, New York; secretary, W. H. Harrington, Boston; treasurer, W. French Smith, Boston; Orlando P. Dexter, New York; John D. Sargeant and Robert Bacon, Boston, and James H. Dawes of Kingston, Mass. The directors are the same as last year, with the exception of the last two.

ANNUAL REPORT OF THE THOMSON-HOUSTON ELECTRIC CO.

The annual report of the Thomson-Houston Co. was presented and adopted April 13. It showed an aggregate business of $10,617,661 for the year, although this total includes only the transactions of the Boston office, it being stated that the returns from the branch offices would increase the operations about 25 per cent. The growth of the business is seen as follows :

1883	$ 426,987 97
1884	700,470 46
1885	983,996 05
1886	1,405,041 74
1887	2,335,594 80
1888	4.435,902 23
1889	8,222,789 12
1890	10,617,661 67

The following is a table of the Thomson-Houston local companies :

	No. of Companies.	No. of Arc Lamps.
January 1, 1883	5	365
January 1, 1884	31	2,878
January 1, 1885	59	5,767
January 1, 1886	100	13.227
January 1, 1887	171	21,840
January 1, 1888	303	36,966
January 1, 1889	419	51,621
January 1, 1890	587	68,203
January 1, 1891	755	87,131

There are companies operating this system in England, Ireland, Sweden, South and Central America, Finland, France, Germany, Italy, Spain, Russia, Japan, West Indies, Australia; in fact, in nearly every civilized country in the world not included in the above.

Of the above, about 500 companies operate both arc and incandescent, employing between 600,000 to 700,000 incandescent lights of the Thomson-Houston manufacture.

There are also many hundreds of isolated plants in factories, hotels, etc., the number of which is rapidly increasing.

There are more than 150 lines of electric railways under contract and in operation, aggregating over 2,000 cars, as a result of less than three years' operation of this department.

It is stated that in spite of the general depression of trade, the orders received during the last 90 days are much in excess of those for the same period in any previous year. The company now has 11 large factory buildings at Lynn, and has 2,400 active customers on its books.

The balance sheet is as follows :

BALANCE SHEET, JANUARY 31, 1891.

ASSETS.

Acc'ts receivable, mdse	$6,505,117 74	
Less deductions	650,511 77	$5,854,685 97
Notes receivable	$1,752,799 25	
Less deductions	87.639 95	1,665,159 30
Cash		632,055 18
Real Estate, about 70 per cent of cost		350,000 00
Machinery and tools, about 70 per cent. of cost		400,000 00
Patterns and models		135,000 00
Patents (1.000)	$438,354 29	
Less deductions, in addition to previous deductions	100,000 00	338,354 29
Local Co.s' stock, 40 per cent. of par		346,430 00
Local Co.s' bonds, 70 per cent. of par		1,646,120 00
Manufacturing Co.s' stock, at cost		3,821,017 50
Construction Co.s' stock, at cost		1,022,500 00
United Securities Co.s' stock, at cost		487,425 00
Consignments		14,095 63
Merchandise inventory		1,476,589 15
Supply department inventory		53,554 68
Common stock, sold but not delivered		331,100 00
Premium on common stock, sold but not delivered		331,100 00
		$18,905 106 70

LIABILITIES.

Capital stock, common		$6,000,000 00
Capi'al stock, preferred		4,000,000 00
Accounts payable, merchandise		374,340 60
Notes payable, collateral		1,587,356 97
Notes payable, unsecured.		765,550 64
Mortgage		1,200 00
Accrued wages		4,124 78
Guarantee account (from accrued surplus)		200,000 00
Surplus February 1, 1890		1,685,415 92
Profits for the year,	$3,091,883 67	
Premium on common stock sold,	1,500,000 00	
Total,	$4,591,883 67	
Less dividends paid on preferred stock,	254,765 88	4,337,117 79
		$18,905,106 70

STATEMENT OF SURPLUS ACCOUNT.

Surplus February 1, 1890	$1,685,415 92	
Increase for year ending January 31, 1891,	4,337,117 79	
Surplus January 31, 1891,		$6,022,533 71

C. A. COFFIN, *Treasurer.*

The subjoined is the statement of the

PROFITS AND SURPLUS ACCOUNT.

	Added to Surplus from Profits.	Total Surplus.
January 1, 1883	$ 17,237 85	....
January 1, 1884	93,696 74	$ 110,934 59
January 1, 1885	96,187 10	207,111 69
January 1, 1886	106,687 50	313,809 19
January 1, 1887	123,006 05	426,815 23
February 1, 1888	313,596 67	750,411 91
February 1, 1889	660,828 82	1.411,240 73
February 1, 1890	1,309.175 19	1,685,515 62
February 2, 1891	4,337,117 79	6,022,533 71

The surplus account, February 1, 1889, was $1,411,240.73 *from which* there was divided among the shareholders $1,000,000 as stock dividend and a cash dividend of $35,000 on preferred stock. There was *added* from the profits of the year 1889, $1,309,175.19 making a surplus February 1, 1890, $1,685,415.92.

In explanation of the small increase in the surplus of 1890 over that of 1889, it should be stated that there were delivered to trustees of Thomson-Houston trust securities "Series D" as a dividend to holders of the common stock, securities and claims amounting at face value to $2,410,289.13.

It is further remarked with regard to the division of profits : "It may be proper, in view of the policy recently adopted of paying cash dividends to the holders of the common stock, to refer to the dividends which have heretofore been received by the stockholders of the company in other than cash payments."

"The profits received from the different 'series' of trust securities, together with dividend of 40,000 shares of common stock computed at $25 per share, have been equivalent to an average annual dividend to the holders of the common stock of a little more than $14 per share during the eight years of the present management of the company. This has no reference to, and does not include the large amounts paid from time to time for rights to subscribe to new issues of the common stock of the company. In addition to these dividends there is an accrued surplus derived from the profits of the company, exclusive of premium received from the sale of common stock of $4,522,533.71."

DIVIDENDS.

SOUTH PITTSBURGH, TENN.—The South Pittsburgh Electric Light & Power Co. has declared a dividend of 5 per cent.

ELECTIONS.

SOMERVILLE, MASS.—At a meeting of the directors of the Somerville Electric Light Co., held March 30, F. Ellwood Smith was elected treasurer and business manager, vice, F. S. Pearson, resigned. After May 1st, the Boston office will be discontinued and all business will be transacted in Somerville.

FALL RIVER, MASS.—The organizers and incorporators of the Fall River Electric Freight Road held a meeting recently and elected the following board of directors : F. L. Ames, Thos. S. Stevens, Jr., Wm. S. Greene, Spencer Borden, Philip L. Saltonstall and Joseph F. Jackson. The following day the directors met and elected Philip L. Saltonstall treasurer, and Joseph F. Jackson clerk of the company.

LANCASTER, N. H.—At the annual meeting of the Lancaster Electric Company, the following officers were elected ; President, H. W. Burgett; secretary and treasurer, W. E. Bullard ; directors, H. W. Burgett, Frank Smith, Lewis H. Rogers.

THE JAMAICA AND BROOKLYN ROAD CO., announces the issue of first mortgage gold bonds to the amount of $500,000, at 99 and accrued interest, payable Jan. 1st, 1930. Subscriptions will be received by the Brooklyn Trust Co.

Society and Club Notes.

NEW YORK ELECTRIC CLUB.

The following ticket was elected at the annual meeting of the club on April 16:—*President*, Samuel Insull; *Vice-Presidents*, Charles W. Price, Erastus Wiman, W. L. Candee, Edward Weston; *Secretary*, S. L. Coles; *Treasurer*, Geo. M. Phelps; *Board of Managers*, H. L. Shippey, P. H. Alexander, T. C. Martin, C. E. Stump, E. F. Peck, E. E. Bartlett, Dr. J. B. DeLery, H. D. Cheever, Chas. D. Shain, Joseph Barré, C. O. Baker, Jr., H. D. Stanley, J. H. Herrick; *Committee on Membership*. Charles Dutton, C. H. Barney, Geo. T. Manson, S. S. Wheeler, Joseph Wetzler.

An exhaustive report and balance sheet prepared for the members by Gen. O. E. Madden, and verified by an expert accountant, showed the club to have a surplus of $3,677, and a membership of 308, not including 19 recently elected.

After the declaration of the result, a vote of thanks was tendered to the tellers. Messrs. Bishop and Colby and to the retiring board of officers. It is proposed to celebrate the fifth anniversary of the club with a dinner on May 5.

THOMSON SCIENTIFIC CLUB.

At the last regular meeting of the Club, the members were entertained by Mr. Howard S. Rodgers, who gave a very interesting talk about the Electric Street Railway systems in Cincinnati, O., telling many amusing anecdotes about the struggles of the pioneers in the business in that city.

Much interesting discussion following regarding the comparative efficiency of single and double trolley systems. The experiment of inviting the ladies to the lectures has proved to be a very pleasant success and of great pleasure to all.

CHICAGO ELECTRIC CLUB.

On Thursday evening, April 16th, the annual election of officers was held. As there were several tickets in the field, the interest evoked was very great, and after a hotly contested election the following ticket was elected:—

President, B. E. Sunny; *Vice-Presidents*, F. B. Badt, Alex. Kempt, D. P. Perry, Geo. C. Bailey; *Secretary*, W. A. Kreidler; *Treasurer*, F. S. Terry; *Managers*, F. E. Degenhardt, chairman, E. Baggot, J. P. Barrett, F. G. Beach, W. H. McKinlock, E. R. Gilman, M. A. Knapp, F. W. Parker, W. B. Pearson, C. H. Wilmerding; *Membership Committee*, C. C. Haskins, Geo. Cutter, G. A. E. Kohler.

Legal Notes.

A QUESTION OF OWNERSHIP.

The Essex Electric Railroad Company directors have been subpoenaed to appear in the United States Circuit Court, May 5, to answer in a bill in equity brought by the Johnson Steel Rail Company to restrain the Essex Company from using the Essex interlocking chair, an invention of Mr. David N. Cook, of Salem. The Johnson Company claim that the Cook chair is an infringement upon its patent and demand damages from the Essex Company. The respondents deny that the Essex or Cook chair is an infringement, the application of its principle to the rail being entirely different from that of the Johnson. The Essex Electric Company is using the Essex chair.

THE NEW ENGLAND PRINTING AND TELEGRAPH CO.

The New England Printing and Telegraph Co. have followed up their petition for a mandamus against the Boston board of aldermen, by a petition of the same sort against H. H. Carter, superintendent of streets. The court is asked to grant a mandamus against Carter to compel him to issue permits to the company to allow them to dig up the streets in which the board of aldermen of 1890 gave the company a right to erect poles.

LYNN, MASS.—The marriage is announced of Mr. A. L. Rohrer, chief electrician of the Thomson-Houston Electric Co at Lynn, to Miss Carrie L. Gould, of that city.

Appointments, Etc.

MR. FRANK PIERCE of St. Paul has been appointed electrician of the Electric Light and Street Railway works at Great Falls, Montana.

MR. GEORGE M. BROWN, for the past five years manager of the Southern New England Telephone Co. in Rockville, Conn., and local operator for the Postal Telegraph Company, has closed his engagement, to accept an excellent position in the central office at Hartford.

MR. E. A. SWEET has concluded his services as electrician for the Electric Light & Power Co., of Milford, Mass. He has been in the employ of the local company about two years.

MR. R. W. GRAY has been appointed to fill the office of city electrician at Waco, Tex., recently created by the city council.

MR. R. W. ROLLINS, district engineer of the Westinghouse Electric Co.'s New England department, will sever his connection with that company on May 1st, to take the position of assistant superintendent of the Hartford (Conn.) Electric Light Co.

MR. GEORGE E. BLISS, electrician at the Malden, Mass., electric light station, has accepted the position of permanent manager of the electric works at Harrison, N. J., and has removed there with his family.

MR. G. W. KÜCHLER has been placed in charge of the electrical department of the Roessler & Hasslacher Chemical Co., of this city, who have been introducing the new insulating material "Isolatine."

MR. THOMAS H. HEALEY, who of late has held a responsible position in the Southern New England telephone office in New Haven, has been promoted to the position of assistant operator of the Hartford Telephone Exchange.

CAPT. J. C. WILSON, who has been the efficient superintendent of the Northwest Electric Company for the past year, goes from Winnipeg to Toronto to re-enter the service of the Edison Company.

MR. HENRY C. EDDY has resigned as Western manager of *The Electrical World*, which position he had gracefully retained for a period of nearly six months.

MR. A. H. CHADBOURNE, lately of Chadbourne Hazelton & Co, has joined the forces of the Westinghouse Electric & Manufacturing Co., and will represent the Company's railway department at their Philadelphia office in the Provident Life Building.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of April 18, 1891, from New York, Boston and Washington.

THE INCANDESCENT LAMP.[1]

BY THOS. G. GRIER.

INCANDESCENT lighting is now merging into a second decade of commercial life, and any neglect on the part of the electrical fraternity to fully understand the importance which the incandescent lamp plays in this growing industry is suicidal to their interests.

The limited knowledge and the absence of any reliable data on incandescent lamps led the Franklin Institute, in 1884, to invite the manufacturers of incandescent lamps to place samples of their lamps in the hands of an impartial committee of experts for a comparitive test. These results were published in September, 1885, and from the official report a few results have been compiled.

Five different manufacturers submitted their lamps, some submitting several batches of different voltages. The lamps were tested for duration or life, aud before placing on test their initial efficiency per spherical candle-power was determined.

The results of the tests showed that the greatest depreciation in candle-power was 50 per cent. and the least 33 per cent. This, however. can not be taken for any comparison as the life of the lamps showed such a great disparity. The depreciation of the Edison lamps, which proved the superior in the test was 35 per cent. These results are looked upon to-day as of little practical value except as historical record, but they have taught us that lamps are a delicate matter to handle, and whether a lamp is a lamp of value depends on many circumstances.

Since 1884 many other makes of lamps have come on the market, and knowledge gained by experience has both improved the quality of the lamps and cheapened the process of manufacturing. In 1884, lamps were advertised for 16 c. p., $3.00; to-day from 40 cents to 60 cents may be taken as an average price.

Six years now have passed since the Franklin Institute experiments, and we are almost as much in the dark as in the earlier days of the industry. The question of life seems to be the most important factor to be considered from the central station point of view, and to meet this desire various manufacturers frequently guarantee the average life of their lamps. Those guaranteeing the longest life and at the same time proving their guarantee usually get the majority of the business.

There is not the least trouble in making an incandescent lamp for any desired life, as the life of a lamp depends upon the efficiency at which it is burned. John W. Howell, in 1888, published a statement based upon the experiment of the Edison Company, which covered five years of time, and the use of thousands of lamps. In this statement he says the life of a lamp burned at two watts efficiency was practically zero; at three watts per candle it was 1,000 hours; at four and three-fourths watts per candle power it was 16,000 hours. This at once shows that the question of life is merely a question of circumstances and may, or may not be, advantageous.

The object of an incandescent lighting station is to produce light. It is necessary to develop electrical energy, but it is the lamp that transforms this electrical energy into light. The electrical energy represents the dollars of the investor and operators of the station, and it is most important that it should be used with the greatest economy to obtain proper reward for the investor. This, of necessity, brings into the question the lamp used; the life, the cost, and the efficiency being the three considerations.

To bring the matter to a point at once we will assume conditions which are perfectly feasible and within the bounds of possibility. First, we will consider that a lamp burning at 4½ watts efficiency will depreciate but a minimum for the first 1,000 hours. We will consider this lamp and the cost of operating it. A lamp at 4½ watts efficiency and 16 c. p., burning for 1,000 hours, would require a total expenditure of electrical energy of 72,000 watt hours. This, at one cent for 50 watt hours would be $14.40, for the current, and, adding 50 cents for the cost of the lamp, would make a total cost of $14.90, for burning this lamp 1,000 hours. The efficiency of another lamp is 3½ watts per c. p. We will not say how many lamps will have to be replaced in the 1,000 hours, but just assume that the efficiency of 3½ watts per c. p. is maintained throughout the 1,000 hours. The total expenditure of energy on this basis will be 56,000 watt hours, which will cost at the rate of one cent for 50 watt hours, $11.20. Adding 50 cents to this for the cost of the first lamp, makes it $11.70, eaving a difference in favor of the 3½ watt lamp of $3.20, which, of course, will have to be used to a certain extent in replacing the amps; but allowing that a 3½ watt lamp will maintain its efficiency for 333 hours, we will merely have to pay $1.00 additional or replacing lamps and have a net saving of $2.20. This, though n assumption, is not distorted, for lamps from 3½ to 4½ watts efficiency are on the market. And yet, many a station is being perated with lamps of a lower efficiency than 4½ watts, and they wonder why it is that their dividends are smaller than those of ther plants. It is the incandescent lamp that will make or break he dividend-paying record of the central station and it should be onsidered with the utmost care. The assumption has been made and the question been analyzed. The lack of actual data makes it necessary to assume and analyze the question as it has just been done. However, the London *Electrical Review* has published some facts which will be analyzed, as this assumption has been, and will show immediately the advisability of maintaining efficient lamps on a circuit, even though their life be short.

The London *Electrical Review* published an account of a test on Edison-Swan lamps and the results were presented in tabulated form, giving the initial candle power, the initial efficiency and the total watts used on the lamp. A test of 1,000 hours duration was started, and at the end of each 100 hours observations were made as to the candle power and the total energy, the efficiency of the lamps being computed and placed in the table. The first four columns of the data are furnished by the *Electrical Review*, the other columns are deductions drawn from the first four columns.

Hrs.	c. p.	Watts per c. p.	Total watts.	Average of each 100 hours.		Cost figured on the basis of 1 cent for 50 watt hours.	
1	2	3	4	5	6	7	8
				Average c. p.	Average total watts.	Cost for each 100 hours.	Cost of 16 c. p. at each 100 hours.

Column 7 shows what the customer pays each 100 hours for the lamp he is using. Column 8 shows what he pays for each 16 c. p. of light he gets for each of the 100 hours. These figures are computed upon the average of the observations; that is, for the first 100 hours the average candle power produced is taken, and so on, for each succeeding 100 hours. The cost of the electrical energy used in the estimate is one cent per 50 watt hours, the prevailing price at the present day.

The potential in these experiments was constant, the same as any ordinary central station endeavors to maintain. The resistance of the filament increases as the lamp continues to burn and the total energy used, when the potential is constant, decreases, and the lamp takes less current to a small extent than when it starts to burn. The relation of the candle power to the total energy shows, that, though less energy is used as the life continues, the economy of the lamp is greatly lessened because the light produced decreases (due to the depreciation of the filament and the discoloration of the glass), in a much greater proportion than the total energy

The financial results in the above table are very clear and plain, and any one would say at a glance, allowing that a 16 candle power lamp costs 50 cents, that it would not cost the consumer a cent more for light if he bought a new lamp at the end of 900 hours, for the saving in current would pay for the lamp; that much is apparent.

Tables were submitted showing that for this grade of lamp at the price of current and price of lamp assumed, though the lamp will last 1,000 hours, it is better to throw the lamp away at the end of 400 hours and use new ones. Seventy-five cents per lamp will be saved every 1,000 hours by replacing the lamps every 400 hours instead of keeping one lamp in 1,000 hours.

If the lamps were cheaper and the currents the same or dearer, it would be cheaper to replace the lamps still oftener than 400 hours. If the current was but half of what is assumed, that is, if the current cost but one cent for 100 watt hours, it would be cheaper to replace the lamps every 700 hours, cheaper by about 17 cents, for every 1,000 hours.

It is not a question of the life of a lamp alone that should determine what lamps should be used, but also the efficiency of the lamp, cost of current and price of lamp. A mathematical equation should be formed taking all these factors into consideration before the matter should be decided by the central station. Reliable data on the majority of the makes of lamps is not obtainable, and it has been necessary to treat the matter from assumption and from analyzing such data as have been published; but even from mere assumption it is without doubt an assured fact, except when the current is extremely cheap that an efficient, short lived lamp is preferable to an inefficient long lived lamp.

In making this mathematical equation, the end in view is to determine the efficiency at which the sum of the costs of power and lamps is a minimum, and in order to do this the rate of variation of life of a lamp with its efficiency should be known. This variation would have to be given by the manufacturer. To give this equation in the shape of a formula we will assume symbols to represent the various factors.

---

[1] Abstract of a paper read before the Chicago Electric Club.

Let A = the number of watt hours required by a 16 c. p. lamp
$A \div 16$ would represent the efficiency per c. p.
" B = the life of the lamp at $A \div 16$ efficiency.
" Y = the cost of a 16 c. p. lamp.
" X = the cost of a watt hour delivered at the lamp.

The value of A and B must be ascertained from the manufacturer.

To obtain the cost of a watt hour, or X, delivered at the lamp, the mean current at the station must be determined. The wires and devices have been figured for a certain loss for maximum current. The energy in transmitting the mean current would bear the same ratio to the percentage, figured for the maximum load, as the mean current does to the maximum current. This amount of energy must be subtracted from the total energy developed and the remainder will give the amount of energy used in the lamps. The total operating expenses, less the cost of the lamps, divided by the total watt hours delivered at the lamps will give the cost of one watt hour.

The cost of operating a 16 c. p. lamp for an hour would be the cost of a watt hour multiplied by the number of watts required by the 16 c. p. lamp, or $X \times A$.

The proportion of cost for replacing lamps would be the price of the lamps divided by the life or $Y \div B$.

The most economical point to run the station would be when the sum of the renewals and the cost of the energy is a minimum or expressed in a formula when $(Y \div B) + (X \times A) =$ a minimum.

To give an example of this we will assume the following conditions. Let cost of lamp = \$0.50 cents; efficiency, $A \div 16 = 4$ watts, or $A = 64$ watts, let X = \$.00016, an average cost of electrical energy, (being .8 of a cent for 50 watt hours); and the life of lamp 1,000 hours and substituting these values in the formula we have, $.501{,}000 + .00016 \times 64 = .0005 + .01024 =$ \$.01074.

Another lamp costs 60 cents, its efficiency is 3 watts or $A = 48$ watts. X = the same as in previous case, \$.00016, and the life of lamp 300 hours, substituting these values in the formula, we have $.60 \div 300 +$ \$$.00016 \times 48 = .002 +$ \$.00768 = \$.00968.

The result shows that a lamp costing 60 cents, and having a life of only 300 hours with 3 watts efficiency, makes the operating expenses of the station less than if the lamp was only 50 cents and had a life of 1,000 hours with 4 watts efficiency, in fact, the 3-watt lamp is cheaper even though the 4-watt lamp cost but one cent and had a life of 10,000 hours, for the cost of the energy alone for the 4-watt lamp is in excess of the sum of the cost of lamp and energy in the case of the 3-watt lamp. The question is governed very much by the cost of the energy.

The success or failure of electric light central stations as a dividend earning investment, is of the utmost moment to the agents, manufacturers of electric light apparatus and others who desire to promote the business. It is necessary for the success of those desiring to promote the electric light business that the electric light central stations make money. For the electric light central stations to be financially successful, those operating them should be convinced of the importance of using efficient lamps and of renewing them as soon as their efficiency materially depreciates.

ELECTRICITY AS APPLIED TO RAILROADING.

In a recent address delivered before the Young Men's Christian Association of the Delaware, Lackawanna and Western R. R., Mr. P. H. Brangs, electrician of the railroad, gave a very complete account of the various ways in which electricity is applied to the operation of railways. He traced the history and nature of the railway telegraph, and showed how it led to the development of railroad signals in which the electric current plays a prominent part. Under this head Mr. Brangs gave the following interesting details:

When the railroads of this country had grown to such proportions that the trains had to be run under short headway, it was found essential to adopt some plan whereby the safety of travelers might be made to depend upon something better than the caution of the engineer, and out of that necessity was developed the block signal.

The first railroad signal that was operated in this country was tested on the old Camden and Amboy railroad, now a part of the Pennsylvania railroad system. It was in the summer of 1863 that the midnight train from Philadelphia was filled with wounded soldiers returning home to Eastern hospitals. The train was delayed by a hot journal at Bristol. One hour later the Washington express from Richmond Junction following it, not knowing of the delay of the preceding train, crashed into it, causing one of the most frightful railroad accidents on record. Mr. Robert Stewart was at that time employed on that road as telegraph superintendent, and was the first man to construct and experiment with railroad signals in this country. Very crude signals were used at first, which were changed from time to time until the present form of semaphores was adopted. In 1870 to 1878 the "block signal" system came into general use throughout the country. The Pennsylvania Railroad Company equipped their entire line from New York to Philadelphia, and during the Centennial year a thorough test of its practicability was made. Not a single accident can now be recalled due to the improper or inefficient operation of this system. The different systems now in use in this country are the Sykes or English block, the Union Switch and Signal Company's electro pneumatic system, the Union Switch and Signal Company's, clockwork system, the Black automatic mechanical block system, the Hall automatic electric system, and numerous others.

In the Switch and Signal Co.'s pneumatic electric block system, in operation for eight miles on the New Jersey Central Railroad, the New York Central, West Shore and others, the blocks vary in length from 1,000 to 1,800 feet, and are operated on four parallel tracks. At the commencement of each block, signal posts are erected, one for each track. Each post carries two semaphores; the upper or home semaphore has a square end and is painted red, the lower or distance signal, being fishtailed in shape and painted green. At night powerful lamps are used. When the upper semaphore projects at right angles from the post, it indicates that a train is on the next block. Whenever it projects at an angle of 30 degrees, the lower one is also set at danger or caution. As the train leaves the block thus protected the upper signal falls, but the fishtail signal remains at caution until the next block is reached and the train is two blocks distant. Each semaphore is connected with a counterweight, so that when left to itself the counterpoise drops by gravity and sets it at danger. Directly below each post is a pneumatic cylinder with a single acting piston, which is connected by means of a balance lever and connecting rod to the semaphore arms. As arranged, the piston which works with the cylinder is pressed upwards to its highest position when the semaphore is set at danger, this, therefore, being the natural position of the whole apparatus.

At the top of the cylinder a valve is arranged which can be opened electrically, and which closes automatically by a spring. To this valve a pipe is connected which communicates with a supply of compressed air. Above the valve is an electro-magnet, the armature of which is connected to the valve stem. If a current of electricity is sent through the magnet, the valve will be opened, compressed air will be admitted above the piston, which will be depressed, and as it goes down will force the semaphore, in opposition to the counterpoise weight, into the "safety" position. The object to be obtained, therefore, is that when a train is on the block in advance of a set of signals, it must, automatically, cut off the current from both, so that they will be drawn into the "danger" position. When the train is on the next block the current must again be permitted to pass through the upper semaphore magnet, forcing it into the "safety" position, but no current must be admitted to the lower semaphore magnet until the second block has been passed.

Another block system, which has been quite extensively introduced on the roads of this country is known as the "Hall system." It was first used on the Eastern Railroad (now Boston and Maine) in 1871. In this system the signal is now operated on a closed circuit, running from the battery through the block track instrument, through the magnet of the signal instrument, through the points of the relay, through the relay magnets and back to the battery, thus completing a circuit which holds the signal to safety simply by the action of the current. By the momentary breaking of the circuit caused by the passage of a train over the closed spring track instrument, the magnets of the relay are demagnetized, the points are separated and the signal falls to "danger" by gravity from lack of force to sustain it in the "safety" position. It will also be seen that any disturbing cause, such as the breaking or crossing of the line wire, the failure of the battery or any of the mechanical parts, the signal will immediately go to danger by the interruption of the circuit. After a signal has been set at danger it can not be restored until the train shall have operated the clear (open) track instrument at the end of the section. The clearing circuit runs from the battery through the open spring instrument, then through the relay magnets, back to the battery. On completing the circuit through the "clear track" instrument, the relay magnets are magnetized, the points of the relay are again brought in contact, the former circuit is therefore completed and the signal again goes to "clear." If a switch on the main line is misplaced, a circuit is broken in a switch machine attached to the switch, which also causes the signal to fall to "danger." The signal instrument is certainly most simple in construction, consisting of a pair of electro-magnets, between the prolonged coils of which revolves an armature. To one wing of this armature is attached the disc, and to the other its counterweight rod, which being lighter than the signal, allows of a gravity movement of the signal whenever the force holding it is withdrawn. In the "Hall Track Instrument" the piston, on being thrown up by depressing the lever, breaks or makes a circuit on the top plate. The piston is operated in an air chamber, which cushions the upward blow and also retards its fall, thus saving all wear to the apparatus.

Mr. Brangs also described the modern system of electric railways and the various applications of lighting, heating, etc., of railroad cars.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED APRIL 14, 1891.

Alarms and Signals :—

Light Signal System, B. J. Noyes and H. F. Eaton, 450,182. Filed April 5, 1889.

A system of light-signals specially adapted for police service.

Non-Interference Signal Box, W. H. Kirnan, 450,239. Filed Aug. 18, 1890.

Relates to the mechanical and electro-magnetic disabling or retaining devices.

Fire Alarm and Telephone System, S. W. Ludlow, 450,245. Filed July 12, 1890.

Combines a fire alarm and telephone system, in which an alarm of fire may be communicated automatically to a telephone exchange over the ordinary telephone circuits.

Thermostat, W. F. Singer. 450,260. Filed July 29, 1890.

Contact-points carried by spring arms ; two independent bottoms of the thermostat box are each held normally in position by fusible plugs.

Electric Time Call, R. Varley, Jr., 450,390. Filed Nov. 18, 1890.

Adapted especially to use in hotels, for calling guests at specified hours.

Heat Annunciator, A. Reinemann, 450,425. Filed May 31, 1890.

A thermostat. A yielding vessel contains two or more chemicals or substances separated by an easily fusible partition. When the partition melts the chemicals combine and evolve gases that expand the yielding vessel, which operation actuates electrical contacts.

Electric Signal, R. H. Gruschow, 450,458. Filed Nov. 21, 1890.

An electric signal system for steamboats for establishing communication between the officer in command and the engineer.

Fire Alarm and Telephone System, S. W. Ludlow, 450,466. Filed Oct. 25, 1890.

Same in purpose as No. 450,245 above.

Electric Call Bell and Indicator, W. Cox, 450,558. Filed April 11, 1890.

Mechanical details for an electric house-call system.

Conductors, Conduits and Insulators :—

Mechanism for Carrying Wires through Conduits, F. A. Wessel, 450,206. Filed Sept. 24, 1890.

A contrivance for sending a wire or cable through a conduit, and operated from the end of the conduit where the wire or cable is inserted. Consists of two self-clamping carriages one of which carries the wire or cable, and which, operated by a rope at the end of a conduit, can be made alternately to clamp themselves against the wall of the conduit and draw one another forward.

Insulator, C. A. Lieb & E. Lavens, 450,294. Filed Dec. 8, 1890.

A "bell" insulator especially adapted for railway conductors.

Electric Wire Insulator, D. A. Bertolette. 450,384. Filed Dec. 12, 1890.

A cylindrical insulator with peculiarly designed water-sheds.

Electric Wire Connection, E. J. Gatley, 450,581. Filed Feb. 7, 1891.

Intended especially for electric arc-light circuits, and adapted for use in connecting lamps to their conducting wires.

Holder for Electric Cables, J. W. Marsh, 450,589. Filed Sept. 12, 1890.

For securing electric cables upon the reels on which they are wound for shipment or storage ; especially intended to protect the cables from moisture and injury.

Distribution :—

System of Electrical Distribution, C. J. Van Depoele, 450,511. Filed Sept. 19, 1890.

Is in part an amplification of the invention patented to the same inventor Sept. 9, 1890, No. 436,275. Consists, chiefly, in employing electro-chemical counter-electromotive force devices as a means for regulating the current supplied to reciprocating electro engines.

Dynamos and Motors :—

Dynamo Electric Machine, W. F. Collins, 450,219. Filed Feb. 18, 1890.

Relates to the construction of the field-magnets.

Insulation of Armatures for Dynamo Electric Machines. R. Eickemeyer, 450,367. Filed Aug. 28, 1890.

The armature drum or core is clothed on its face with an inner layer of narrow insulating material laid diagonally from end to end, and an outer layer of the same laid diagonally but reversely to the inner layer ; the whole being then well charged with liquified or adhesive insulation.

Automatic Switch for Electric Motors, F. E. Whipple, 450,441. Filed Oct. 13, 1890.

A rheostatic switch of the class adapted to apply current to a motor in gradually increasing amount.

Electro-Magnetic Reciprocating Engine, C. J. Van Depoele, 450,543. Filed Dec. 29, 1890.

Comprises a magnetic shield or envelope, motor coils within the envelope, a magnetic system adapted to be reciprocated within the motor coils, and magnetic extensions from the envelope toward the interior of the coils.

Pulsating Current Electric Motor, C. J. Van Depoele, 450,544. Filed May, 26, 1890.

Combines, with a source of continuous and pulsating currents, a motor having a closed circuit armature encompassed by an inducing coil in circuit with the source of pulsating current, and field-magnets of constant polarity reacting upon the poles induced in the armature.

Armature, Lam. C. Atwood, 450,552. Filed Oct. 28, 1890.

Design and details of construction for a ring armature.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, W. A. Crowdus, 450,285. Filed Oct. 8, 1890.

Battery cell has a metallic trough in its bottom and a conductor leading from the trough to the exterior ; a bath of mercury is placed in the metal trough and the lower end of an electrode is immersed in the bath of mercury, whereby the mercury forms connection between the electrode and the metallic trough.

Porous Cells for Galvanic Batteries, W. Burnley, 450,354. Filed Oct. 21, 1890.

Consists of a shell of pasteboard or wood veneer.

Lamps and Appurtenances :—

Art of Making Filaments for Electric Lighting, S. F. Van Choate, 450,304. Filed May 31, 1890.

Consists of a filament or base built up and composed of aluminum and iodine ; the filament is built up by electroplating from a liquid solution composed of alcohol, iodine and aluminum ; the liquid solution is composed substantially in the proportion of one pound of alcohol, three grains of crystalized iodine and two grains of aluminum.

Measurement :—

Instrument for Measuring Electric Currents, H. H. Cunynghame, F. L. Rawson and O. E. Woodhouse, 450,121. Filed April 1, 1887.

An electro-magnet has oppositly arranged poles, an armature is mounted on a vertical axis between said poles, the horizontal axis of which corresponds to that of the electro-magnet, a torsional spring is connected to the armature.

Medical and Surgical :—

Regulator for Electro Therapeutic Apparatus, J. H, Davis, 450,577. Filed May 12, 1890.

A rheostatic regulator for medical batteries.

Miscellaneous :—

Multiple-Fuse Cut-out, A. W. Jones, 450,159. Filed Dec. 6, 1890.

Relates to a multiple fuse cut-out in which a series of fusible strips are so arranged and combined in relation to movable and fixed contacts that the fusible strips may be successively brought into circuit as required.

Circuit Closer, W. C. Johnston, Jr., 450,292. Filed December 17, 1888.

A circuit closer in which the contact surfaces slide over each other especially designed to prevent the accumulation of foreign matter between the contacts and to keep them polished.

Rheotome, G. E. Pragnell, 450 319, Filed April 12, 1890.

An automatic circuit breaker especially adapted to electric bells.

Electric Switch, F. Adam & J. Knapik, 450,551. Filed Nov. 18, 1890.

A "snap" switch for incandescent light circuits.

Railways and Appliances :—

Trolley for Electric Railways, A. S. Hickley, 450,153. Filed Apr. 14, 1890.

So constructed that upon encountering an obstruction the trolley and its immediate support will be separated from the supporting arm without breaking ; the invention also includes lubricating devices for the trolley wheel.

Non-Sparking Clamp for Trolley Wires, C. A. Lieb, 450,163. Filed Nov. 28, 1890.

Combines with a holder for trolley wires a flexible current conveying device adjacent to the holder and in electrical connection with the wire. The flexible or yielding metallic current conveyer engages with the trolley wheel during the entire time that it is adjacent to the hanger, thus preventing sparking in case of "jumping" between the trolley wheel and the trolley wire.

Electric Railway Wire Support, C. A. Lieb, 450,164. Filed Dec. 10, 1890.

A strain equalizer to neutralize the effects of expansion and contraction.

Electric Switch for Electric Railways, F. Mansfield, 450,172. Filed Nov. 18, 1890.

For connecting and disconnecting branch conductors of an electric railway with the main conductor ; adapted for use with the electric railway system patented to the same inventor July 22, 1890, Nos. 432,673, 432,674, and 432,675.

Electric Switch for Electric Railways, F. Mansfield, 450,173. Filed Nov. 18, 1890.

For making and breaking the circuit of electric railways and adapted to the system shown in the patents enumerated in the entry next above.

Trolley Device, A. Palmros, 450,184. Filed Jan. 8, 1891.

Trolley designed and constructed to adjust itself automatically to the circuit wire upon curves, switches, etc.

Rail-Connection with Supplemental Wire, C. A. Robinson, 450,198. Filed Sept. 22, 1890.

Claim 1 follows :

The combination, in an electric railway system, of the rails, a parallel copper rod connecting the sections of the same, a supplemental return circuit wire running longitudinally between the rails, and a copper strap connecting said rod and supplemental wire.

Trolley-Wire Support, C. A. Lieb, 450,242. Filed Nov. 14, 1890.

Comprises a cross-bolt, a threaded metallic piece through which the cross bolt passes, and insulating material between them.

Trolley Guide, W. E. Jackson, Jr., 450,489. Filed Nov. 14, 1890.

Has a guide or finder pivoted to the trolley pole below the wheel, and actuated by an electro-magnet on the upper end of the pole, the guide or finder being normally held depressed, but adapted to be thrown upward upon occasion.

Reciprocating Electric Railway Motor System, C. J. Van Depoele, 450,542 Filed Sept. 19, 1890.

Claim 1 follows :

A reciprocating electric railway motor system, the combination, with the vehicle to be driven, of a source of defined rising and falling current moving therewith, a reciprocating motor concentric with the axle thereof and having a plurality of motor coils, each provided with a movable magnetic piston directly connected thereto, and means for supplying the defined currents to the motor coils in succession.

Electric Railway, R. M. Hunter, 450,586. Filed June 4, 1889.

Claim 2 follows :

In a branching electric railway, a main line conductor and a branch line conductor extending along the main line and branch tracks, respectively, and electrically connected, in combination with two distinctly located generators, one connected to the main line conductor and the other connected to the branch line conductor.

Electric Wire Supporter, C. A. Lieb and E. Lavens, 450,587. Filed Dec. 8, 1890.

A supporter of the "bell insulator" type, especially adapted to railway conductors.

Telegraphs :—

Printing Telegraph, P. H. Fisk, 450,228. Filed Oct. 17, 1890.

A system for connecting electrically a series of any number of typewriters at distant points.

Telegraph Relay, R. O. Wickes, 450,272. Filed Dec. 8, 1890.

A relay designed and constructed with special reference to facility of adjustment.

Telephones and Apparatus :—

Auxiliary Mouth-Piece for Telephones, W. N. Marcus, 450,858. Filed Feb. 10, 1891.

An adjustable tube and mouth-piece.

Receiving Telephone Support, W. N. Marcus, 450,359. Filed Feb. 10, 1891.

A bracket support for telephone receivers.

Electrical Apparatus for Reproducing Sounds, J. E. Roulez, 450,426. Filed Oct. 9, 1890.

A microphone.

Consists of a membrane or diaphragm of semi-conducting material, having one terminal conductor connected to it, in combination with one or more insulated blocks, to which the other conductor is connected, these blocks being also of semi-conducting material and secured to and supported solely by the membrane or diaphragm.

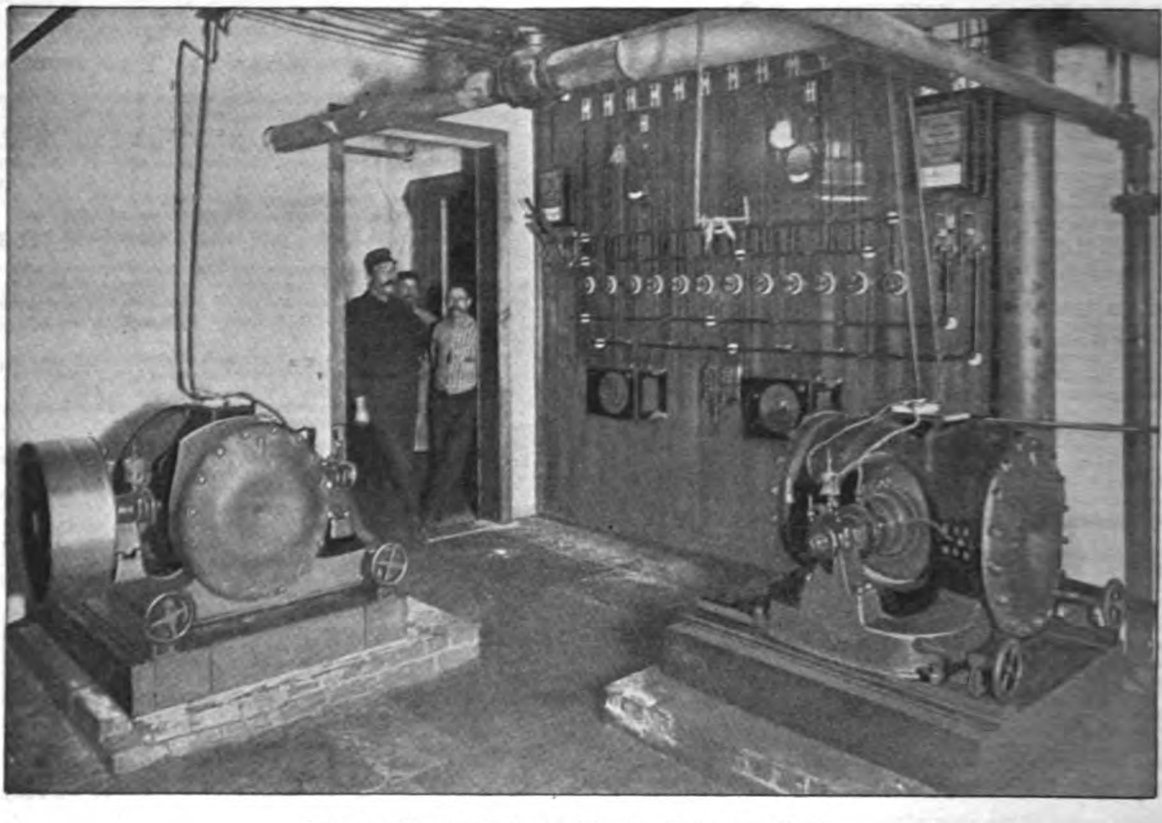
THE ELECTRIC LIGHT PLANT IN THE GENESEE HOTEL AT BUFFALO, N. Y.

It is a noticeable feature, and becoming more and more common every day, that all hotels and large buildings are utilizing electric light with its numerous advantages of cleanliness, better diffusion of light, and ease of manipulation.

One of the finest incandescent light plants recently installed in northwestern New York is that in the Genesee Hotel at Buffalo. This plant is especially noteworthy for its successful and efficient operation, the very thorough manner in which the whole plant has been put in, and the artistic distribution of the lights.

The plant was installed by Messrs. F. P. Little & Co., the well-known constructing and consulting electrical engineers of Buffalo, the contract for the engines and dynamos having been awarded to Mr. P. P. Beals, the New York State agent of the Wenstrom Consolidated Dynamo & Motor Co., of Baltimore, Md., whose electrical apparatus is used.

The generating plant in the Genesee Hotel, which is shown in the accompanying engraving, comprises two Wenstrom, 110 volt, shunt wound dynamos, of 250 lights capacity each, which are belted direct to Rice automatic high speed engines, built by the John T. Noye Mfg. Co., of Buffalo, one of which is 26 h. p., and the other 40 h. p., the latter engine being also used to operate other machinery. Steam for running the engines is supplied by three boilers, placed in a spacious boiler room adjacent to the dynamo room, one of 55 h. p., one of 45, and one of 30, two, only, of which are in general use, the other being a reserve. The elevator, pumps, and steam heat, in addition to the electric plant, are supplied from these boilers.



DYNAMO ROOM, GENESEE HOTEL, BUFFALO, N. Y.

The principal features of the Wenstrom dynamo, it will be remembered, are the iron clad field magnets, where the magnetizing coils are surrounded by iron, preventing loss of the magnetic lines, reducing the amount of wire required to a minimum, and effecting a saving of power; and the embedding of the armature conductors in the core, this permitting of the least interpolar space between the armature and pole pieces, and reducing the amount of magnetization required for any given electro-motive force. The noticeable qualities of these machines, due to the above construction are, quiet running and slow speed. The machines, in fact, make only 570 revolutions per minute, one of the engines running at 280, and the other at 260 revolutions per minute.

The switch-board, which is placed in the dynamo room, is a most thorough and complete piece of work, and is equipped with ammeters, voltmeters, cut-outs and switches. There are twelve circuits at present running to the board, including arc lamp circuits, two "Universal" arc lamps for running on incandescent circuits being employed, the operation of which is highly satisfactory; the lamps give a brilliant and steady light without flickering, hissing or flaming. Each circuit is fitted with double pole switches, and the lights are so arranged that those on any floor can be cut out in the dynamo room at the switch-board Three large, double pole main switches are employed, enabling the dynamo machines to be coupled in multiple, or either one of them placed on one or any number of the circuits.

The circuits are connected to two sets of bus bars, allowing of running in multiple, or dividing the circuits as desired, between the two machines. The well-known tubes of the Interior Conduit system are used for covering the bus bars and wires on the switch-board, making a very neat and effective method of insulating these parts of the system from damages or injury that might occur if run uninsulated. The wiring is most complete, and has been carried out in a most thorough and workman-like manner. The drop in voltage from the centre of distribution is 2 per cent.

The work on the first, second and third floors, and the front portions of the fourth and fifth, is all concealed, "Grimshaw" wire being used throughout, and in the other parts of the plant, where open cleat work has been installed, "Shield Brand" weather proof wire is used. There are also three large and handsome stores in connection with the building which are very attractively and well lighted. On all the circuits and on each floor are placed cut-outs, and the usual safety devices. The two Universal arc lamps which are used for exterior lighting, are run in series between the incandescent mains, and absorb about eight amperes of current, giving a very clear, white, and thoroughly reliable light. "Edison" incandescent lamps are used throughout. This plant is one of the many recent improvements made in the Genesee Hotel, and adds much to its appearance, comfort and attractiveness.

The hotel is at present wired for 700 lights, but it is not unlikely that this number will be increased within the near future. The lighting in the café, bar and rotunda of the hotel, has been especially well carried out, and the lamps are most tastefully and artistically arranged, giving a very beautiful effect and delicate diffusion of the light.

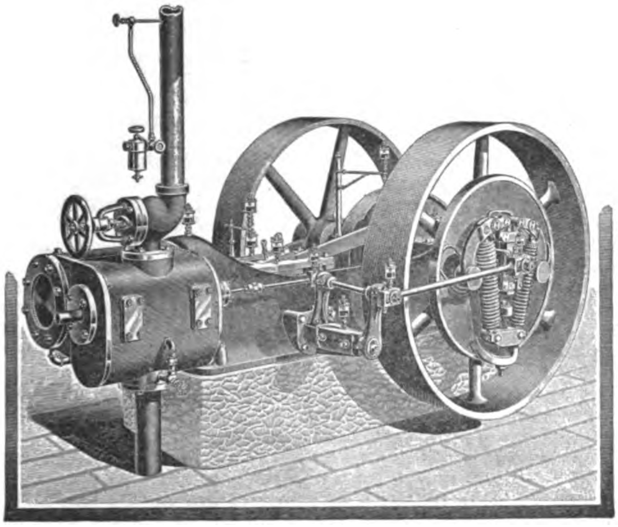
This is but one of the many fine plants which have been installed by F. P. Little & Co. Among others recently put in may be mentioned a 1,000 incandescent light plant for Shea & Co., and a National alternating plant in the John T. Noye Mfg. Co.'s factory. Also a "Wood" 80 light arc machine in the city plant at Penn Yan, N. Y., which has just been started and is giving most excellent satisfaction. The city lighting plant using the Western Electric Co.'s system at New Castle, Pa., was also installed by them, as well as the electric street railway plant there, of the Thomson-Houston system. A 1,000 incandescent National alternating plant of their construction exists at Clyde, N. Y., where they are also building a city arc lighting plant.

TRADE NOTES AND NOVELTIES
AND MECHANICAL DEPARTMENT.

No matter how quickly an industry grows, the persistent advertiser is always in touch with it and he is known to every new consumer.

THE ERIE CITY AUTOMATIC ENGINE.

The Erie City, Pa., Iron Works automatic cut-off engines, illustrated herewith, are made from entirely new designs and patterns. The beds are well proportioned and very strong, and are provided with new patent pillow blocks or main bearings, which have square surfaces with an improved form of gib, to allow for taking up the wear. The gib is adjusted by a set screw tapped through the solid bed, and provided on its inner end by ball and socket joint, to allow for perfect adjustment.



Erie City Automatic Engine.

The steam chest is made detachable from the cylinder. The valve is large and simple in its construction, is provided with water grooves for packing, is accurately fitted, and perfectly balanced. The water packing avoids the use of packing rings or springs, which are more or less liable to get out of order and cause trouble. besides taking a great deal of power to move, and putting unnecessary strain on the governor.

The governor plate is strong and heavily ribbed on the back, and the springs are arranged close to the plate, to avoid undue vibration. The adjusting screw is placed on the same side of the plates as the weights, which brings all the strains in one plane, with the result that the governor is very sensitive and insures close regulation. The eccentric rod is driven from an eccentric pin instead of eccentric and strap. The piston rods are fitted by screwing them into the crosshead with U. S. standard threads, having jam nut to check up behind. This obviates the keying of the eccentric rod and crosshead, which not infrequently causes trouble, when the key is driven too far down. The piston is also secured on the rod by U. S. standard threads, and the ends of the rod are riveted over. The rocker is made with a take-up gib on one side, and has two strong arms through which a steel shaft is passed.

The engine is well built and well proportioned throughout, and careful tests prove it to be one of the best high speed engines now on the market.

B. F. STURTEVANT & CO.

The rapidly increasing business of the Chicago Branch House of the B. F. Sturtevant Co., of Boston, has necessitated its removal to new and much larger quarters at 16 South Canal street, Chicago, where an entire new building furnishes ample accomodations for the large stock of blowers, exhausters, heating and ventilating apparatus, portable forges and steam engines. This branch will remain under the control of Foss & Noble, and will form the headquarters for the trade of the Middle and Western States. The stock will be greatly increased in order to provide for immediate shipment in all cases, and a corps of experienced engineers will be maintained for estimating upon and installing plants for heating, drying, ventilating, etc.

B. & S. INSULATING MATERIALS.

The B. & S. Electric Equipment Co. have recently placed on the market a line of elastic insulating paints, compounds, and waxes suitable for covering line wires, making splices or filling junction boxes and tubes. The pole and cross-arm paints are manufactured solely for this purpose, and are unsurpassed for durability and appearance by any in the market. These paints and compounds embody the results of many years experience of an expert manufacturing chemist in this special line of work.

The favor with which they are being received by telegraph and electric light companies, shows that really good articles of this kind at a moderate price are needed. A list of the material kept on hand is given below, but any special paint or compound to meet special conditions will be manufactured. B. & S. Elastic Hard Black Wax; B. &. S. Black Elastic Insulating Compound; B. & S. Elastic Black Weatherproof Compound; B. & S. Elastic Black Insulating Compound, No. 2; B. & S. Elastic Black Weatherproof Insulating Compound; B. & S. Elastic "White Core" Compound; B. & S. Elastic "White Core" Paste; B. & S. Elastic Clear Varnish; B. & S. Elastic Black Hard Finish, or air drying Elastic Japan; B. & S. Acid and Alkali Proof Varnish; B. & S. Black Telegraph Cross-arm Paint; B. & S. Bright Red Telegraph Cross-arm Paint; B. & S. Quick Drying Telegraph Pole Paint; Black, Dark Bronze, Green, and Medium Bronze Green; B. & S. Linseed Oil Black Priming Paint.

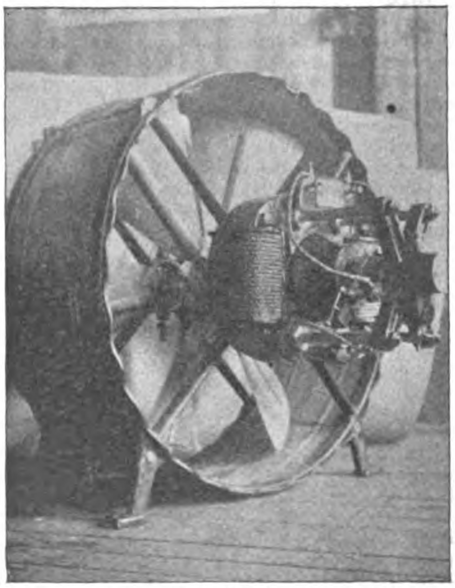
SILICON BRONZE TROLLEY WIRE.

The Aluminum Brass and Bronze Co. of Bridgeport, Conn. have issued a very artistic little pamphlet containing testimonials from electric railways all over the country in praise of their silicon bronze trolley wire. This wire seems to be giving the best of satisfaction wherever used, and is daily growing in popularity.

WING FAN AND RIKER ELECTRIC MOTOR COMBINATION.

The accompanying illustration shows the combined Wing fan and Riker electric motor, now being introduced by the L. J. Wing Co., of 126 Liberty St., N. Y.

All users of machinery concede that in any machine requiring power it is desirable, when possible, to obtain a motive power which will be compact, self-contained, and form a part of the machine to be operated. Especially is this a requisite where the machine to be operated is more or less isolated, as is generally the case with a fan. All these conditions are completely filled by this outfit. Being an electric motor, it is necessary only to wire to the motor. This saves the expense of, and attention demanded by, steam pipes, shafting, belting, and many other objectionable features under the old conditions.



Combined Wing Fan and Riker Motor.

The electric fans may be arranged to run at different speeds, are clean, perfectly rigid and moisture proof, and are constructed throughout in the best manner. They attain, in the smaller sizes, a commercial efficiency of 85 per cent., which increases in proportion to the size of the fan. These outfits have been in use for two seasons with excellent results, and are now about to enter on their third season with important improvements.

THE TAPER SLEEVE FRICTION CLUTCH PULLEYS.

THE subject of friction clutches has become within a comparatively brief period a very important one, and is to-day attracting the attention of all progressive builders and users of machinery; and no mill, factory, or manufacturing establishment is now complete without its friction-clutch pulleys and friction-clutch couplings to connect and disconnect its machines and lines of shafting without stopping or slacking the speed of the engine.

The accompanying illustrations, Figs. 1 and 2, represent the friction-clutch made by the Taper Sleeve Pulley Works, of Erie, Pa.

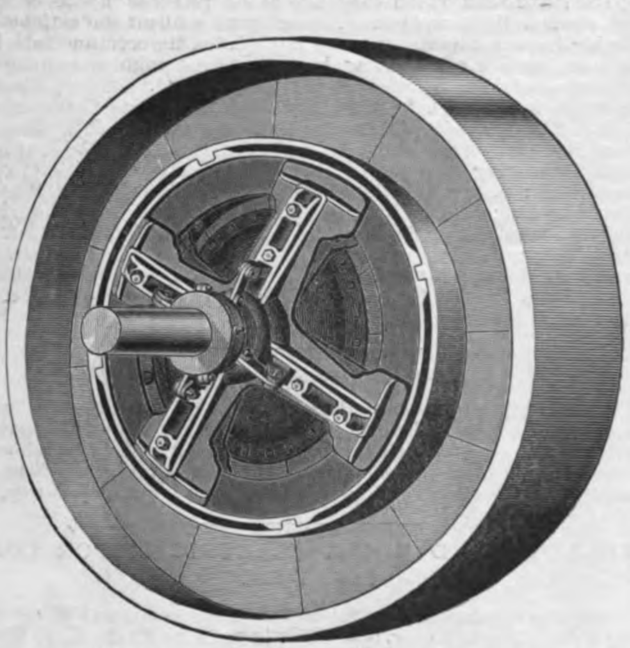


FIG. 1.—TAPER SLEEVE PULLEY CLUTCH.

The web of the pulley is constructed of several segmental pieces, as shown in Fig. 1, in each of which the grain of the wood is in a radial line from centre to circumference, and the rim or face is constructed by building up a series of rings on either side of the outer edge of the web.

As wood does not shrink or swell perceptibly in the line of the length of the grain, and as the grain of the web is disposed radially from the centre and confined by the rim from circumferential displacement—it is impossible for the pulley to get out of shape. These pulleys average from one-quarter to one-third the weight of iron pulleys of similar dimensions.

As shown in Fig. 2, the clutch pulley has a long hub fitted with lubricators, in which the shaft turns when the clutch is disengaged, leaving the pulley, belt and machine at rest. The clutch, which is keyed to the shaft and revolves with it, consists of a vise-like arrangement of iron jaws, the gripping parts of which are shod with maple blocks, which are brought together or closed by compound levers, operated by a toggle-joint cone, and which are so pivoted as to open by centrifugal action, aided by powerful springs, when the cone is thrown out. The action of these jaws may be as gradual as desired, being adjustable at will, and is sure, strong and noiseless.

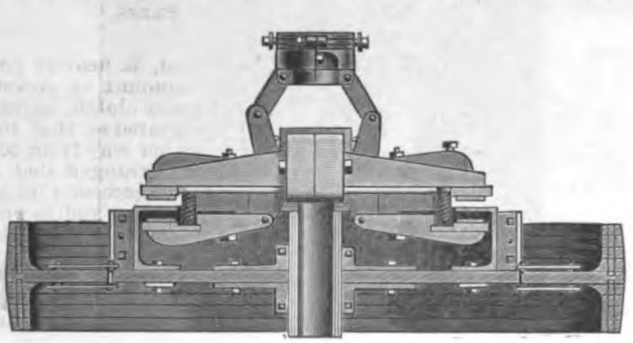

FIG. 2.—TAPER SLEEVE PULLEY CLUTCH.

When it is desired to start the pulley, the cone, which is operated by a shifting lever, is gradually pushed in, and these maple-faced jaws grip the outer and inner faces of the polished friction ring, which is bolted to the web of the pulley, at first slipping and moving the pulley but slightly, and taking hold more and more as the operator pushes home the cone, until a positive hold is attained and the pulley has reached the full speed of the shaft.

A NOTEWORTHY ELECTRIC LIGHT PLANT.

An opportunity was given to electrical engineers recently to inspect the electric lighting plant at the new dry goods store of Messrs. H. C. F. Koch & Co., on 125th street, this city, which is deserving of special mention, on account of the thorough manner in which every detail of the work has been carried out.

The current is generated in the basement, from two Thomson-Houston compound wound dynamos, one of 800 light, and one of 400 light capacity. Each machine is driven by an independent high speed "Ideal" engine of 80 and 40 horse-power, respectively, which, with a separate circuit to every floor, insures light to the building at all times.

Heavy foundations have been provided for this machinery, effectually preventing vibration from being transmitted to any part of the building. The belt centres have been made exceptionally long, with light, noiseless running as a result.

The main switchboard is located in the dynamo room, and is so arranged as to allow the machines to operate together or alone on any or all circuits. It is made of enameled slate and has voltmeters, ammeters, rheostats, switches, and all necessary controlling devices upon it.

The basement has 136 lights—on fixtures in the china and toy department, elsewhere suspended from silk cords. The first floor is lighted by 246 ground glass lamps, placed on beautiful fixtures arranged in seven long rows the length of the store. The show window deserves special mention, being lighted as is no other window of its kind in New York. The lights here are placed against the ceiling, with 12-inch, double glass, reflectors for each light. There are ten lights to each window, making forty in all. These reflectors are the feature of the show window lighting, being made of glass, front and back, the space between filled with a mercury compound, and hermetically sealed. They never tarnish, are extremely bright, and with ground glass lamps reflect a powerful but soft light. These reflectors are manufactured by the Thackara Manufacturing Co., of Philadelphia.

The second floor is lighted by 216 lamps, all on fixtures, as on the floor below, except for a few reflectors in dark places. The lamps on the third floor, 200 in number, are mostly on fixtures, while on the fourth floor 200 silk drops are used, the wiring being on insulators and all exposed.

A good idea of the lighting is given when we state that there are 172 ceiling fixtures, 265 silk cord drops, 41 receptacles, 57 reflector lights, 4 newel fixtures, 3 bracket fixtures; or a total of 542 outlets and 1,007 16-candle power lights.

There are 100 switches, giving absolute and convenient control of all lights. Grimshaw White Core wire has been used, it being placed in mouldings run on the stringers in the air spaces between the floors and iron ceiling. The mains from the basement are run in mouldings placed in position by plugging walls and screwing thereto. They are finished to conform with the surrounding woodwork. All concealed moulding is painted inside and out with P. & B. waterproof paint. All lights are controlled by switches located in the main pocket, one for each floor, where all fuses are also placed.

This plant is simple in its design and construction, and is especially flexible in its control. The work was designed by, and executed under the direct supervision of, the consulting engineer, Charles H. Davis, C. E. The contractors were: Electric plant and wiring, Thomson-Houston Electric Co.; fixtures, The Mitchell-Vance Co.; and engines, W. R. Fleming & Co.

The following summary of apparatus and material will be of interest: One 62,000 watt Thomson-Houston dynamo; 500 amperes at 125 volts, capacity 800 16 c. p. lamps, weight, 10,000 pounds, 900 revolutions per minute. One 30,000 watt Thomson-Houston dynamo; 240 amperes at 125 volts, capacity 400 16 c. p. lamps, weight, 5,000 pounds, 1,174 revolutions a minute. Five miles of "Grimshaw" wire; 74 Thomson-Houston vertical switches; 10 Thomson-Houston knife switches; main switchboard of enameled slate 6 feet by 4 feet; five panel boards of enameled slate with all local switches placed thereon; 1,007 16 c. p. lamps and 542 outlets; 172 ceiling fixture pendants; four newel fixtures; three bracket fixtures; 41 receptacles; 265 silk cord drops; 57 reflectors. The total cost was about $13,000.

CHARGING STATIONS FOR ELECTRIC LAUNCHES ON THE THAMES.

Woodhouse & Rawson United Limited, have arranged for the erection of a permanent charging station on the banks of the river at Chertsey, under the management of Mr. J. Taylor. The station is now in course of erection, and will be quite ready to undertake the charging of all sizes of electric launches by the beginning of the river season. Why would not such a scheme work in New York, in Central Park; and in Brooklyn, in Prospect Park; or even on the Harlem?

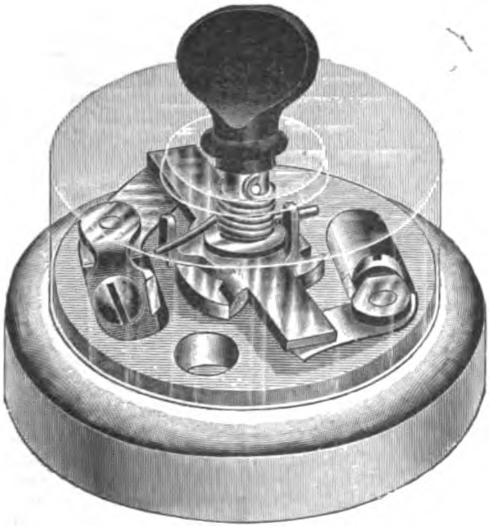
THE BARR CO.'S ELECTRIC CIGAR LIGHTER.

The accompanying illustration shows a form of electric cigar lighter, now being manufactured and handled by the Barr Electric Mfg. Co., of 19 Broadway, New York. The demand for a cheap, reliable and decorative cigar lighter for office or residence use, has given rise to this form of apparatus which seems to "fill the bill" in every particular. The lighter being of the primary battery type, needs no connection with power or light circuits, and therefore has the advantage of being portable. The ornamental case has a glass lining containing the ordinary bichromate of potash battery solution with carbon and zinc elements. When not actually in use the zinc is kept clear of the solution by a spiral spring, the compression of which dips the zinc in the solution, heating to incandescence a platinum strip. While this idea is not entirely new, there is one thing about the device which is new and of the greatest value; heretofore the difficulty has been that the pressure of the cigar or material to be lighted has borne directly, or almost directly, against the incandescent platinum strip, the result being that the strip is soon broken or impaired.

The device shown above is provided with an orifice into which a little alcohol soaked sponge is pressed that does not allow the lighter even to touch the platinum strip, ignition taking place promptly on account of proximity to the fuse of the alcohol. Taken all in all, the device is a happy combination of usefulness and safety with the æsthetic requirements of ornate bric-a-brac. One charge of the battery should last between 30 and 60 days and should cost only about 10 cents.

THE SPERRY SPECIAL SNAP SWITCH, THE "4S."

Mr. Elmer A. Sperry, while supposedly spending all his time in building mining machinery or in engineering problems of like magnitude, seems to find time to develop other inventions, which, though not so pretentious, are quite as useful in their way. His very latest, and one which has not in any manner been referred to before is the "4S" or "Sperry special snap switch," shown in the accompanying illustration. The action of this very novel incandescent switch is different from anything that has hitherto been made. It does away entirely with the dogs or other small parts, the working parts consisting of but two pieces, both of which can be easily seen in the drawing, viz., the spring and lever. The ratchet which controls the movement of the lever forms part of the base of the switch. The double break made by this switch measures more than 1¾ inches, and will break several times the voltage ordinarily used. The action of the lever upon the terminal contact always keeps the contact surfaces clean and bright, and friction, or any other than positive mechanical movements, is entirely dispensed with in the working of this switch.



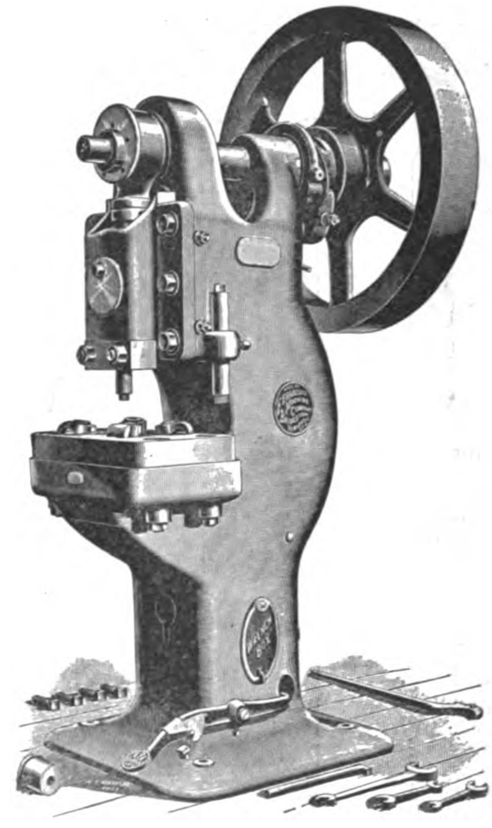
The Sperry 4s Switch.

The handle is so arranged as to unscrew when turned backward for removing the cover, thus giving easy access to the interior. A number of new and special features of construction have been utilized, among them the method of making connection. The terminal is depressed below the surface at an angle so that the screw driver can easily reach it from the top, requiring no extra perforation for the admission of the wires, which are always open to inspection upon simply removing the cover.

This switch is extremely neat in appearance, the base for the 10 ampere size measuring less than three inches over all, and some very remarkable feats have been accomplished by it in breaking large currents at high potentials. On the whole it is one of the most novel and thoroughly practical of the recent developments in the field of electrical supplies. It is manufactured and sold by the Sperry Electric Mining Machine Co., of Chicago.

A NEW PUNCHING PRESS.

The accompanying illustration shows a new style of punching press lately built by the Ferracute Machine Co., of Bridgeton, New Jersey. This press is of new design and has a number of features not embodied in other presses for the same kind of work.



The New Ferracute Punching Press.

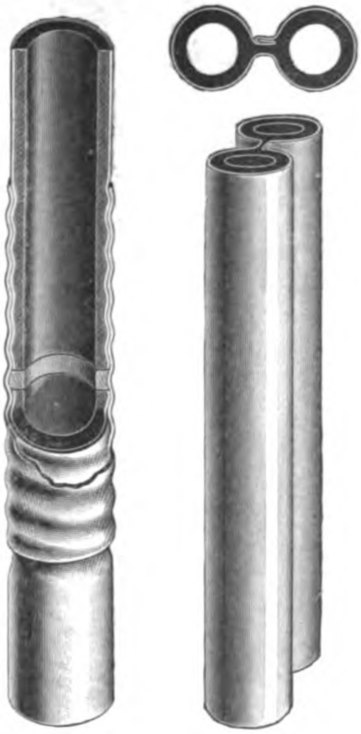
The frame is much higher with more bed-room, is heavier and has a larger fly-wheel, thus giving a greater amount of power. It also has a new form of improved automatic clutch, adjustable for different speeds, and adjustable when geared so that the press may be stopped either up or 30 degrees either way from top of stroke for special work. This clutch is so arranged that it does away with nearly all the friction usually necessary in an automatic clutch, is very durable in its construction, and is provided with a safety-pin, so that it is not necessary to remove the belt when setting dies. It is connected with the treadle, which has a lock arrangement, so that the press can either be run continuously or stopped at each stroke if desired. The fly-wheel has a steel disc with four recesses so that the clutch-slide will engage every fourth of a revolution.

The slide-bar adjustment is of new form so as to vary the height of the ram or slide-bar very considerably, and can be adjusted and locked in a moment. It is graduated so that each degree indicates $\frac{1}{100}$ in height, which is a very convenient feature in setting and recording dies. It can also be used in giving a series of blows with gradually increasing pressure. It has a special form of bolster-plate with sliding-clamps so that almost any dies can be held in it. It also has a new form of stripper-clamps and many other features which are a great convenience and which are not generally embodied in other makes of presses.

These presses are of excellent design and finish and already large numbers of them are in use. There are five sizes. There are also five sizes of corresponding presses with a gear wheel on the main shaft instead of a fly-wheel, and with pinion and fast and loose pulley on the lower shaft, thus giving a slower motion, which is desirable for various kinds of work, and these have about 80 per cent. or 40 per cent. more power. There are a number of attachments which can be used to advantage in these presses, such as pans, shelf, etc., and also shearing and punching apparatus of various kinds. These presses can be used not only for ordinary shearing and punching, but for cutting out blanks, forming them up, and a great variety of other work. They are especially adapted for a great variety of electrical work, such as cutting out and forming up various parts of telegraph instruments, punching and shearing heavy work for dynamos, etc. The general dimensions of the press 53 shown are as follows: Weight without extra appliances, about 3,500 lbs.; height from floor to top of fly-wheel, 83″; hole through bed front to back, 8″; hole through bed, right to left, 10″; stroke of slide-bar, 1½″; weight of fly-wheel, 735 lbs. Other dimensions are given for this press and other sizes in a handsomely illustrated price list issued by the Ferracute Machine Co.

NEW FORMS OF "INTERIOR CONDUIT" TUBING.

We illustrate herewith a new article of manufacture, designed and placed upon the market by the enterprising and energetic Interior Conduit & Insulation Company. The Company has been frequently called upon to furnish a metal covered tube for decorative purposes, extra protection against mechanical injury, absolute fire proofing and protection against deleterious elements of cement. Fig. 1 illustrates the perfection of the metal covered tube. Their well-known interior tube is drawn through a die and an outer covering of either brass, steel or iron drawn upon it, fastened and securely sealed by an ingenious lapping of the seam. The tubes are joined together by their familiar screw couplings. In order to guard against any liability of moisture or condensation, providing a leak to the outer covering of the tube, a pliable washer is inserted between the two abutting ends of the tube. Fig. 2 shows two separate tubes covered with one piece of metal drawn on as the one above described. This double tube will be made in sizes one-quarter and five-sixteenths inch inside diameter, and will be found very useful as a substitute for moulding, and will be used largely for exposed work. It is needless to say that both of the above tubes may be highly polished or finished in any color metal.



FIGS. 1 AND 2.—NEW INTERIOR CONDUITS.

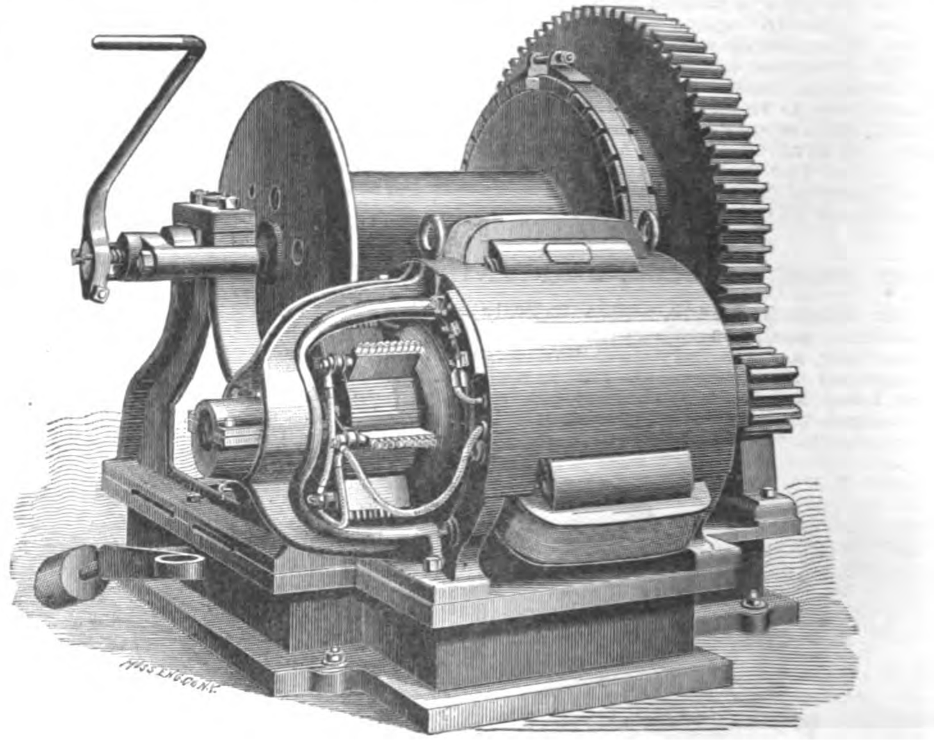
MULTIPLE ELECTRIC GAS LIGHTING APPARATUS.

Mr. A. L. Bogart, 22 Union Square, New York, has just published a pamphlet containing full and explicit instructions for the installation and mode of operating multiple electric gas lighting apparatus. Copies will be mailed to applicants on receipt of twenty-five cents each; in lots of 25 or over, 15 cents each. This pamphlet will interest the most experienced adept, and an amateur can successfully install, and practically operate a multiple electric gas-lighting plant by strictly following the directions contained therein.

PERRET SINGLE REDUCTION ELECTRIC HOIST.

WE illustrate below an Electric Dock Hoist brought out several months since by the Elektron Mfg. Co. This is a piece of machinery where the single reduction and slow speed with which Mr. Perret has been so successful a pioneer, are particularly desirable, on account of the saving in space, noise, friction and consumption of current. The motor is a 15 h. p. Perret multipolar, making 450 revolutions per minute, geared by a gun-metal pinion to a 38 inch gear on the drum shaft of hoist. The drum is 1 ft. in diameter, giving a speed on hoisting rope of a little over 200 ft. per minute.

The motor is shunt wound, and drives the gear wheel at a constant speed, which may be increased, if desired, by the introduction of resistance in the field circuit. By depressing the hand lever the hoisting drum is forced against a friction device revolving with the gear wheel and lifts the load, its speed varying with the pressure on the lever. To lower the load the foot lever is depressed and the hand lever raised. The whole machine is very compact and simple, and is built to stand rough dock usage. The motor is water-proof and has all the latest improvements.



THE ELEKTRON HOIST.

THE HEISLER ELECTRIC LIGHT SYSTEM.

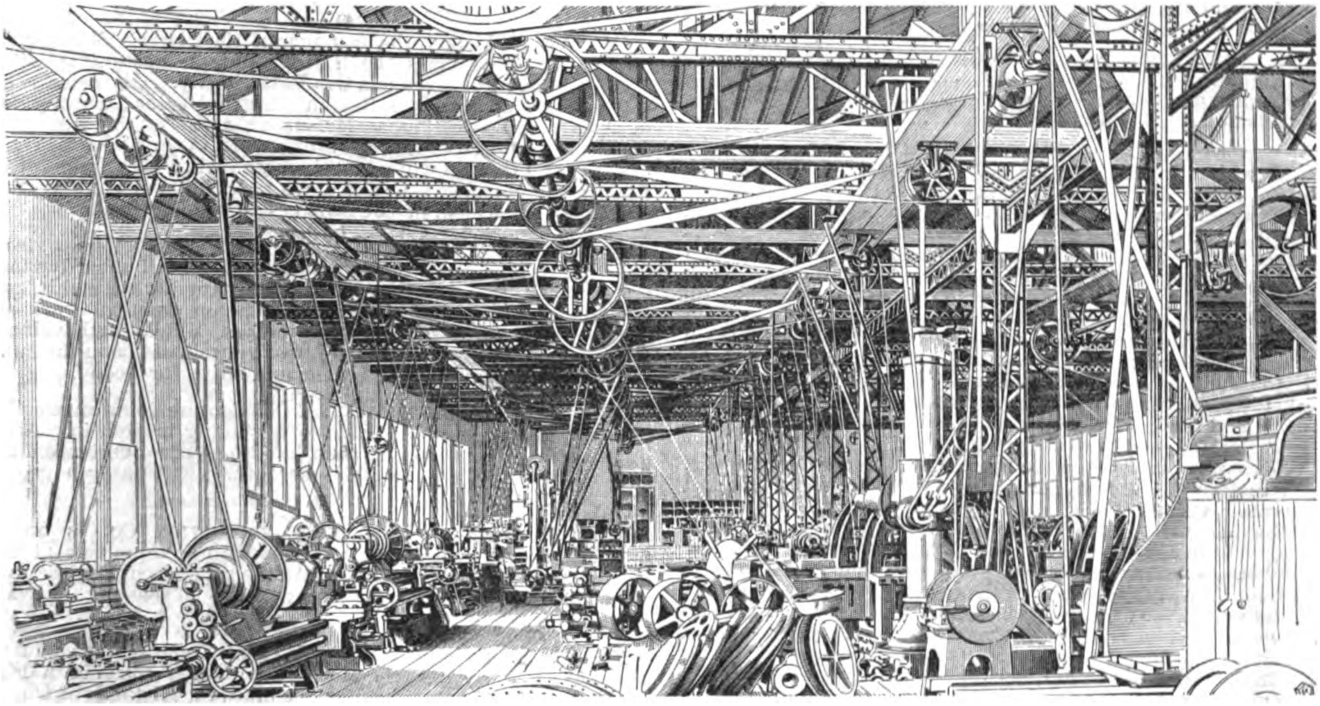
The Heisler Electric Light Co., of Philadelphia, have consummated arrangements with the Interstate Complete Electric Construction Co., of St. Louis, to act as their agents for the State of Missouri and adjacent territory, and also to carry in stock a full line of material and repairs. Practically speaking, they will maintain an establishment to take care of all wants of the Heisler system in their territory. The Heisler Co. have also consummated similar arrangements with Messrs. M. V. Smith & Son, of Belton, Texas, for the State of Texas and a portion of Mexico. These people will conduct an establishment, equipped similar to the Interstate Complete Electric Construction Co. Thus the Heisler Co. are gradually establishing their business at various points in such a manner that users of their apparatus will be thoroughly protected from any unnecessary delay in the receipt of supplies or repairs. They have lately closed contracts for several installations, among them, Bellevue, O.; Marine City, Mich.; Colorado, Texas; Montgomery, Ala.; and extension of plant at Lampasas, Texas; Belton, Texas; and Wauseon, O.; and the outlook for business is very brilliant. As yet they have not completed arrangements for carrying out their lamp shop extension, principally because of their being so driven on their regular line of work.

THE ARMINGTON & SIMS' ENGINE CO.

A very neat and tasteful little folder has been issued by the above company, of Providence, R. I., in which they call attention to a further reduction in the price of their engines, following up the revision of the price list made a year ago. They are now building over 100 different sizes of standard engines from 10 to 500 h. p. They build heavy engines from 70 h. p. to 500 h. p., and compound engines from 100 h. p. to 1,000 h. p. The demand is large and growing for their three cylinder engines for rolling mills and electric power stations, where the sudden and extreme fluctuations of load are very trying to all but the best engines. The last page of this folder gives the names of the various concerns now representing these engines in the different sections of the country.

MACHINE SHOP AT TITUSVILLE, PA.

In the newer central stations it is becoming the practice to use iron largely in the roof construction, and the method has many obvious advantages. The reasons are practically the same as those which bear on the construction of machine shops. As the matter is one of importance to those engaged in electric light and power work, the accompanying view of a new machine shop just put up by the Berlin Iron Bridge Co., for the Titusville, Pa., Iron Co. will be found of interest.



Machine Shop of the Titusville Iron Company.

The building is 70 feet in width by 205 feet in length inside of walls. The roof trusses are made of iron and so arranged as to carry shafting. Along the central portion of the building is a row of iron columns. The trusses are placed 10 feet apart. Where large amounts of shafting are to be carried from the roof, iron trusses are better adapted for the work than wood, as they are stronger and stiffer and there is no danger of their shrinking and swelling from the action of the weather. An iron truss, when placed in position, will stand firmly and carry its load without vibration or deflection.

THE NATIONAL TELEPHONE CO.

The National Telephone Manufacturing Co. is the name of a corporation in Boston, that has been patiently at work, during the past few months, improving its telephones, besides selling to the public its service for short distance lines between house and stable, office and mills, etc. It has just completed the installation of 12 telephones, or stations, in the immense factory of the Portsmouth Shoe Co., at Portsmouth, N. H., connecting directly with the office, all of the different floors and departments. The building is nearly 400 feet long—six stories high. The service enables the superintendent to communicate or talk with every floor, without disturbing any but the station signalled. In one room alone, there are 300 sewing machines operated. Only a personal visit can enable one to realize the difficulties and obstructions that have been surmounted.

THE ALBRECHT ELECTRIC GOVERNOR.

An Albrecht electric governor has been ordered by the Bangor Electric Light & Power Company to be placed in the plant at Veazie. The machine is so constructed that it governs water wheels, dispensing with all labor.

THE ELECTRIC SIGNAL CLOCK CO.

The Electric Signal Clock Co., Harrisburg, Pa., with a capital of $50,000 has been granted a charter. There are 1,000 shares, held by Dr. H. W. Fishel, Dillsburg, York County; John L. McCaskey, Waynesboro, Franklin County; and R. Willis Fair, of Saltsburg, Indiana County. The directors are H. W. Fishel, R. Willis Fair, H. C. Brenneman, York; John W. Holtzinger, Dr. J. W. Ellenberger, Harrisburg; Dr. Walter Pearce, John L. McCaskey, Waynesboro.

A NEW GAS COMPANY.

Recently a movement has been on foot in New Bedford, Mass., to organize a new company for handling and manufacturing the non-explosive and sanitary gas patented by Gen. Eugene de Beauharnais, and now arrangements have nearly reached completion. A new company has been formed between Gen. Beauharnais and the promoters of the proposed Co-operative Electric Company, and in a few days the organization will be complete.

THE MILLER ELECTRIC DANGER SIGNAL CO.

The Miller Electric Danger Signal Company has been formed in Portland, Me., with the following officers: President, William Y. Ober; treasurer, Horace A. Roberts; clerk, Benjamin G. Ward. Directors: William Y. Ober, Horace A. Roberts, Eugene E. Hill, Alonzo H. Whitten, Stephen S. Marsh, Mial W. Chase, George E. Miller. The capital stock is $1,000,000.

UNIVERSAL ARC LAMPS.

The Universal Arc Lamp Co., 16 and 18 Broad street, have received an order for 14 of their lamps to run on the incandescent circuits of the New Jersey Central Railroad terminus in Jersey City. The order was awarded on the merit of the lamps after sharp competition.

Lowell, Mass.—The Bradbury Storage Battery Company has been organized by the election of the following officers: President, E. W. Lovejoy; vice-president, F. W. Puffer; secretary, F. J. Stone; treasurer, P. B. Randlett; directors to act with the above officers, S. K. Dexter, E. S. Moss, J. Y. Bradbury.

THE LOOMIS PLANT, TAMPA BAY HOTEL, TAMPA, FLORIDA.

The electrical plant in the Tampa Bay Hotel was recently installed by the Eureka Electric Company, of 18 Broadwaw, New York, and every care has been taken to make this a model hotel plant in all respects. A number of novelties in electric lighting have been introduced, and a special feature in connection with this plant, is an incandescent night-lamp; one being placed in each of the principal bed-rooms, and so arranged that the occupant can keep it burning all night at such a degree of brilliancy as desired, making it more convenient than gas, and especially desirable in case of sickness, when pure air is of such importance.

All ceiling lights are placed as high as possible, in order to give a better distribution and a more subdued light. The fixtures are arranged for clusters of electric lights, set within a few inches of the plaster, and backed by mirror reflectors. These clusters are controlled by switches set on the casings of the doors, so that a guest may both enter and leave a room while it is lighted. The music room, diningroom, and ladies' parlor are very brilliantly lighted. On the ceiling at one end of the music room is a five point star composed of 50 lamps; at the other end of this room is a large dome, around which there are two circles of lights, thirty in one and twenty in the other, while on the wall, back of the stage, hangs a thirty light crescent, the emblem of the hotel.

The total hotel plant consists of 2,500 lights of sixteen candle power each, distributed as follows:—

Main Building	1,700	Lights
Dining Room	500	"
Kitchen and Servants' Quarters	200	"
Outside Lights and Power House	100	"

The power house is a separate building about 300 feet from the hotel, in which are located the boilers, engines and dynamos. There are three Babcock & Wilcox boilers of 105 h. p. capacity each, and two Logan boilers with a capacity of 60 h. p. each; three 110 h. p. high speed engines made by the Taylor Manufacturing Co., cylinders 18" x 15", and revolutions 270; steam pressure 90 lbs.; five Loomis automatic incandescent dynamos of 500 lights capacity each; and the switch board controlling the entire plant. The foundations for engines and dynamos are laid on a substantial sub-base of concrete, and built of hard burned brick, and Portland cement. The durability and firmness of the foundations will be appreciated when it is known that on a test, a nickel was balanced on edge on each of the three engine cylinders, and the vibration occasioned by throwing on and off a full load was not enough to disturb it.

The dynamos are arranged to run either in multiple or singly, using a method invented by Mr. Osborn P. Loomis, and covered by patents. On the top of each dynamo, is placed a transfer switch having three contact points, to run the dynamo in multiple, singly, or to cut it out altogether. The arrangement of "bus" bars and cables is such that when running machines in multiple, the output of one machine passes through the series coil of the next, and by the use of the switches, on top of the dynamos, any two or more machines may be run in multiple. Any dynamo can be cut either in or out of multiple, without, in any way, changing the voltage. No rheostats or other regulating devices are used by the Loomis system, as the dynamos are absolutely automatic and require no hand-regulation. The connections from dynamos to switch-board are made by soft-drawn bare copper bars run through porcelain insulators.

The switch-board, which is made of mahogany, contains five Loomis ampere meters, one Loomis automatic ground detector, one direct-reading Weston voltmeter, one seven-point voltmeter switch, and 12 plug circuit switches. The cables from the switch-board to the hotel are run underground in a special conduit, and consist of six circuits of 4/0 cable. The "drop" between dynamos and the farthest lamp, with full load, is 8%, and the difference in potential between any two lamps does not exceed one volt.

Besides the lighting plant, the Eureka Electric Company has installed all the electric bells; furnishing a 400 drop annunciator, made of mahogany and beautifully carved. The wiring has been done in such a manner that at any future time, telephones can be substituted for call bells.

Grimshaw "white core" wire has been used throughout for electric lighting, and, including the bell work, over 60 miles of wire have been used in the installation of this plant.

The Tampa Bay Hotel is the only fire-proof hotel built for the Southern season or tourist travel in the United States, and is most sumptuous and liberal in its appointments, accommodations and furnishings. It was designed by J. A. Wood, of New York, architect of several other season resort hotels, both North and South.

HABIRSHAW WIRES AND CABLES.

The Engineering Equipment Company have become Eastern agents for the well-known Habirshaw wires, cables and cores. The Habirshaw flame-proof wire is attracting considerable attention, especially as the new Underwriter rules require its use. Now that the India Rubber and Gutta Percha Insulating Company, who manufacture exclusively the Habirshaw wires, have secured a new and fine factory at Yonkers, the output of this wire will be increased materially by the facilities afforded by the new works.

As the Engineering Equipment Company advertise in this issue, their offices will be found, from about May 1st, in the "Central Building," No. 143 Liberty street, N. Y. City, but the stock room for Habirshaw wire and Underwood belts will be continued at 78 Cortlandt street, which has been the temporary office of this new company.

THE STANLEY TRANSFORMERS.

An extremely tasteful and pretty pamphlet descriptive and illustrative of their transformers has just been issued by the Stanley Electric Mfg. Co., of Pittsfield, Mass. These transformers were lately brought to notice in our pages, and are already in active demand. At present they are made in six sizes, varying from 5 to 100 lamps, and larger sizes can be had if inquired for. The converter is shown in a couple of excellent woodcuts, which, like the pamphlet itself, are the production of Bartlett & Co., the engravers, of this city.

WESTERN TRADE NOTES.

Mr. W. R. Mason, the manager of the Electric Merchandise Co., of Chicago, reports the Spring trade as opening up with a rush. He expects to make a trip East shortly. His recent election as president of the Burton Electric Heater Company, is a most excellent selection, as Mr. Mason is one of the most wide-awake, shrewd and energetic business men in the electrical trade, but it is said that he will meet his match when Mr. Mason, of the Electric Merchandise Co. goes down to Richmond, Va., to make a deal with Mr. Mason, of the Burton Electric Heater Co.

The Bain Electric Mfg. Co., of 47 and 49 S. Jefferson street, Chicago, have issued a very complete catalogue of their dynamos and motors; in fact, it goes considerably further than this, as it contains a vast amount of information on practical work and the operation of dynamos and motors, simple and valuable formula and highly useful tables. A copy should be in the hands of every electrical man, and all should write for a copy.

The Electrical Supply Co., of Chicago, are doing an excellent business, and the Spring trade is beginning to pour in. About June 1st they will remove to their handsome new quarters on Randolph and Michigan avenue, where they will carry a greater stock than ever.

The Continental Electric Construction Co. is one of Chicago's new electrical organizations with headquarters at 1118 Chamber of Commerce building. As their name implies, they will pay special attention to the constructing of electric railways, light and power plants.

Mr. G. A. E. Kohler, the Western representative of the well-known Eddy Electric Motor Company, is placing a large number of their highly popular machines for all kinds of work.

The Central Electric Co., with their usual enterprise, have just secured the General Western Agency for the New York and Ohio Company's lamp, made at Warren, Ohio. This is the celebrated Packard lamp that is so favorably known among consumers, and is considered by practical men to be one of the very best incandescent lamps yet produced. The new American ammeters and voltmeters, lately described in these columns as among the Central Electric Company's new specialties, are now ready for delivery. They are put up in a handsome box with a handy carrying strap and present an elegant appearance. The published price list shows the instruments to be so low in cost that every one connected with an electric plant of any importance can have one.

Mr. J. W. Freeman, of Joplin, Mo. is manufacturing dynamos and motors in his foundry in that city. The system is one invented by a Mr. Lowe, who is associated with Mr. Freeman, and the machines thus far produced by them have given entire satisfaction.

Mr. W. L. Browne, of Plattsmouth, Neb., is making a tour of inspection of the towns bordering Puget Sound, with a view to starting an electric equipment factory.

THE
Electrical Engineer.

Vol. XI. APRIL 29, 1891. No. 156.

COST OF ELECTRIC POWER.—COMPARATIVE EFFICIENCY OF LARGE AND SMALL MOTORS.

BY

S. S. Wheeler.

THE comparison of efficiencies for motors of different sizes has not been given much prominence, the demonstration of the advantages of power transmission of electricity over any other means having so far absorbed much of the spare time of engineers. The subject of the comparison of sizes is nevertheless of great and growing importance, since in practice it determines some important points, among them, the varying rates of charge for large and small power, the best size of machine for use, etc.

Amperes Required to Give Different Powers on The Various Constant Potential Circuits, Allowing For The Ordinary Efficiency of Each Size of Motor.

The accompanying tables, prepared by Prof. F. B. Crocker and the writer, show at a glance the average practical commercial efficiency of motors of all sizes, and the amounts of current required by each when running at full load upon any of the standard circuits.

As a preliminary to all calculations of current consumed it is, of course, necessary to fix upon a definite efficiency for each size of motor, and the efficiencies here given are a general average, based upon the opinions of the leading experts of several motor companies, obtained by us from time to time with a view to preparing an honest table. The efficiencies will undoubtedly seem low to a great many. They certainly are much lower than the results claimed by nearly every manufacturer of electrical motors, but in placing them at the figures given, we have intended to allow for the performances of machinery under the average conditions of long continued use, taking into consideration the effects of overload and underload, abuse, dirt, etc. As the power consumed is subject to constant variation in most cases, motors in operation are seldom working at that rate at which they are most economical. Hence the efficiencies should be placed a little low in a table which aims to hit the results most frequently obtained in actual practice.

The efficiencies of arc circuit motors, are placed lower than those on constant potential circuits for several reasons. Arc motors are usually run with a regulator, which cannot be quite as economical as the regulation of the constant potential machine. The current of the arc motor, being always at the maximum, the loss by resistance (C^2R) is always at a maximum, even when the motor is running with light load. Again, the disturbances due to considerable fluctuations of the current (not found in constant potential circuits) cause slight losses.

In the tables the number of amperes given for incandescent or constant potential motors shows the current required to give the stated mechanical horse power in each case, and the number of volts given in the table of arc circuit or constant current motors, represent the E. M. F. required at the terminals of the motors to give the same power. Both sets of figures are obtained by calculation from the electrical horse power, allowing for the average of efficiency of each size of motor. The formula used in both tables is as follows;

$$\frac{746}{\begin{array}{c}\text{Amperes of an "arc" circuit}\\ \text{or}\\ \text{volts of an incandescent circuit.}\end{array} \times \begin{array}{l}\text{Efficiency of the motor,}\\ \text{expressed as a decimal}\\ \text{fraction.}\end{array}} = \begin{array}{c}\text{the amount given}\\ \text{in table.}\end{array}$$

An examination of the table shows that the efficiencies range from 40 to 90 per cent., which, compared with the steam engine, shows considerable superiority. The consumption of coal in steam engines of various sizes and types, varies from 2 to 10 lbs. per horse power hour, a variation of 1 to 5 against 1 to 2 with electric motors. Further consideration shows that the amount of energy required to produce a given amount of power is not affected by the size of the motor, within moderate limits; the gain in efficiency, if an unnecessarily large motor is used, being about offset by the losses due to its not being fully loaded. For instance, if 1 h. p. is obtained from a 2 h. p. motor, the motor itself, being larger, will be of slightly greater efficiency; but not being run at its best load the result will be only about the same as if a 1 h. p. machine were used.

In other words, for any given amount of power consumed, the amount of energy required, and, therefore, the cost of running, is practically constant and independent of the size of the motor used, within the ordinary limits of selection. This, however, refers merely to the cost of current and is not to be understood as lessening the imperative importance, for mechanical reasons, of choosing a motor with a considerable margin of capacity.

VOLTS REQUIRED TO GIVE DIFFERENT POWERS ON VARIOUS ARC CIRCUITS, ALLOWING FOR THE ORDINARY EFFICIENCY OF EACH SIZE OF MOTOR.

TESTING STEEL AND IRON.

A SWEDISH engineer has recently applied electricity to testing steel and iron for its hardness. It is well known that an electric current of sufficient strength will fuse a thin slip of metal or wire when passed through it. By making a number of experiments the engineer has founnd the strengths of current required to fuse test pieces of iron and steel of different degrees of hardness, and has formed a scale of currents corresponding to a scale of hardness. In order to find the hardness of a particular test piece of the metal it is only necessary to find the current required to fuse it, and this can easily be done by means of an amperemeter. The corresponding figure on the scale gives the hardness of the piece.

THE NEW EDISON DIRECT CONNECTED TRIPLE EXPANSION ENGINE AND GENERATOR.

THE inauguration of the first Edison central station in Pearl street, New York, in 1882 may be said to have firmly established the system of electrical distribution from a centre, which has now grown to be one of the greatest industries in the world. This station embodied not only many original ideas in the generation and distribution of the electric current, but, in more than one way, embraced principles of mechanical operation which have since been proved by experience to be correct and conducive to the highest economy in operation. Mindful of the fact that every step in the transmission of the power of the engine to the shaft of the dynamo must necessarily involve some loss, Mr. Edison at that early date appreciated the benefits to be derived from the direct connection of the engine to the shaft of the armature. To this must be added the consideration of the space occupied by, and money invested in, counter shafting, belting, etc., which in large stations will readily be recognized as involving a large outlay in capital, in addition to the fixed charges required for their maintenance. These considerations, with many others, led Mr. Edison to the construction of his historical "Jumbo" machines driven direct by the Armington & Sims and also the Porter-Allen steam engines. Although these machines might be crude in the light of the present day, the solidity of the design was even then such that not a few of these early machines were until quite recently in successful operation in this city in their original position, and a number of them are still successfully at work in the large Edison station in Milan, Italy. Although this original practice of direct connection was departed from later on, the fact has, within recent years, again forced itself upon engineers that central station practice, in order to obtain the highest commercial efficiency, requires thorough economy in every detail and especially in the generating plant. Indeed, we may divide every system of distribution under practically four heads: the engine, including the boiler; the dynamo; the conductors; and the lamp or motor. As the efficiency of the lamps, conductors and dynamos, may be said to be a fixed quantity which can be well calculated out beforehand, it is evident that the success of the plant must be largely dependent upon the engine as the prime source of power and the method of its connection with the dynamo. If, with direct connection, therefore, an engine be employed giving the greatest output with the least consumption of fuel under the boiler, the ideal conditions of economical distribution will have been reached.

The recent advances which have been made in engine building, therefore, ought to find one of their principal applications in the generation and distribution of electricity, and it is with this in view that the Edison General Electric Company have applied the most improved form of engine in a manner calculated, we believe, to have a most marked influence on the future central station practice of this country. Briefly stated, the Edison Company propose to build their compound triple expansion engine not only for generators of the largest type, but also for those of the smallest capacity practicable with this type of engine, thus making each type a unit with engine and dynamo directly connected. In employing the direct method of driving it is evident that the machine must be designed for the speeds practically obtainable under these conditions, and for this purpose evidently the multipolar dynamo is the most suitable. The general design for the larger type of this combination is shown in the accompanying engravings, Figs. 2 and 3, which show a front and side elevation of what is known as the 2-75 kilo-watt type, in which two 6-pole generators are employed, attached to either end of the main crank shaft, driven by a three-cylinder triple expansion condensing engine. Another type of this combination is illustrated in Fig. 1, which gives a view of the machine now erected in the central power station at the Schenectady works of the Edison General Electric Com-

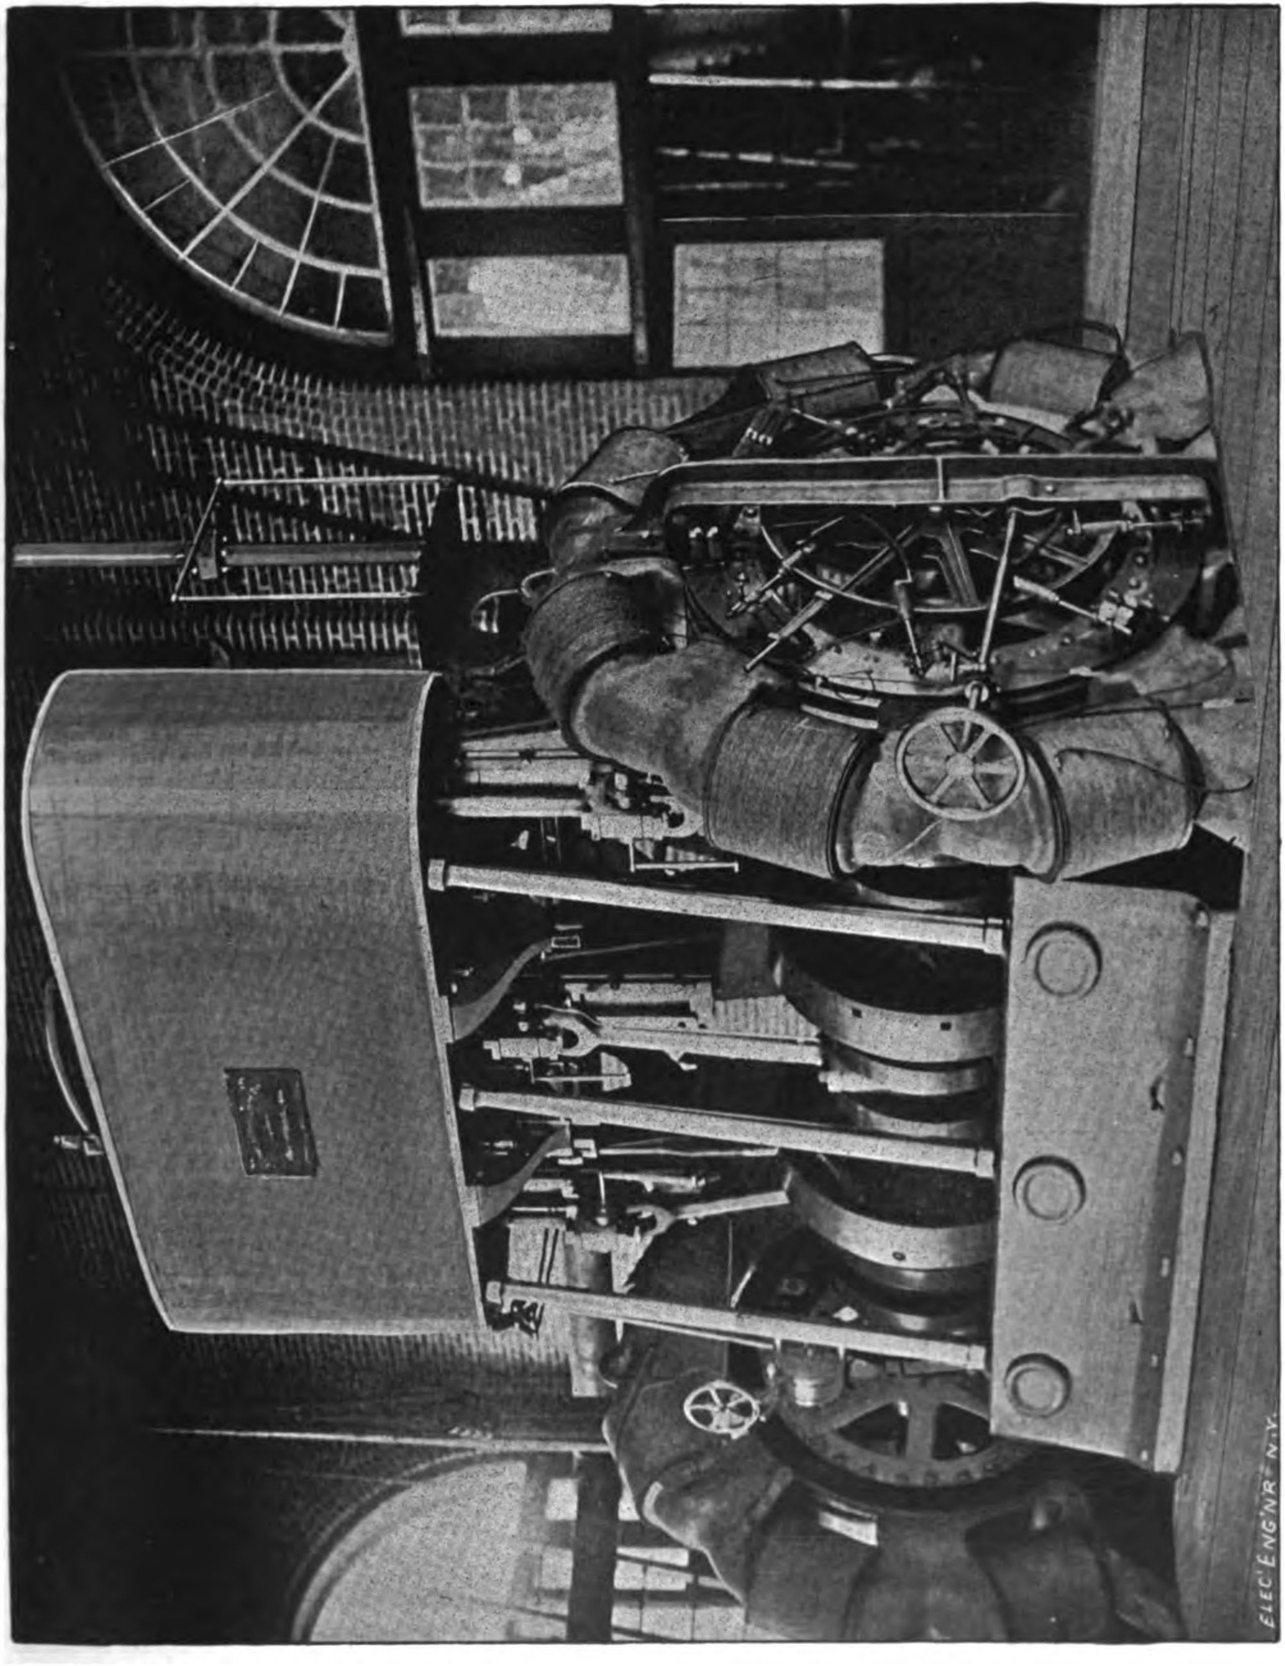

FIG. 1.—COMBINATION OF EDISON GENERAL ELECTRIC CO.'S NEW TRIPLE EXPANSION VERTICAL ENGINE AND NEW EDISON MULTIPOLAR GENERATORS:—OVER 300 H. P. CAPACITY.

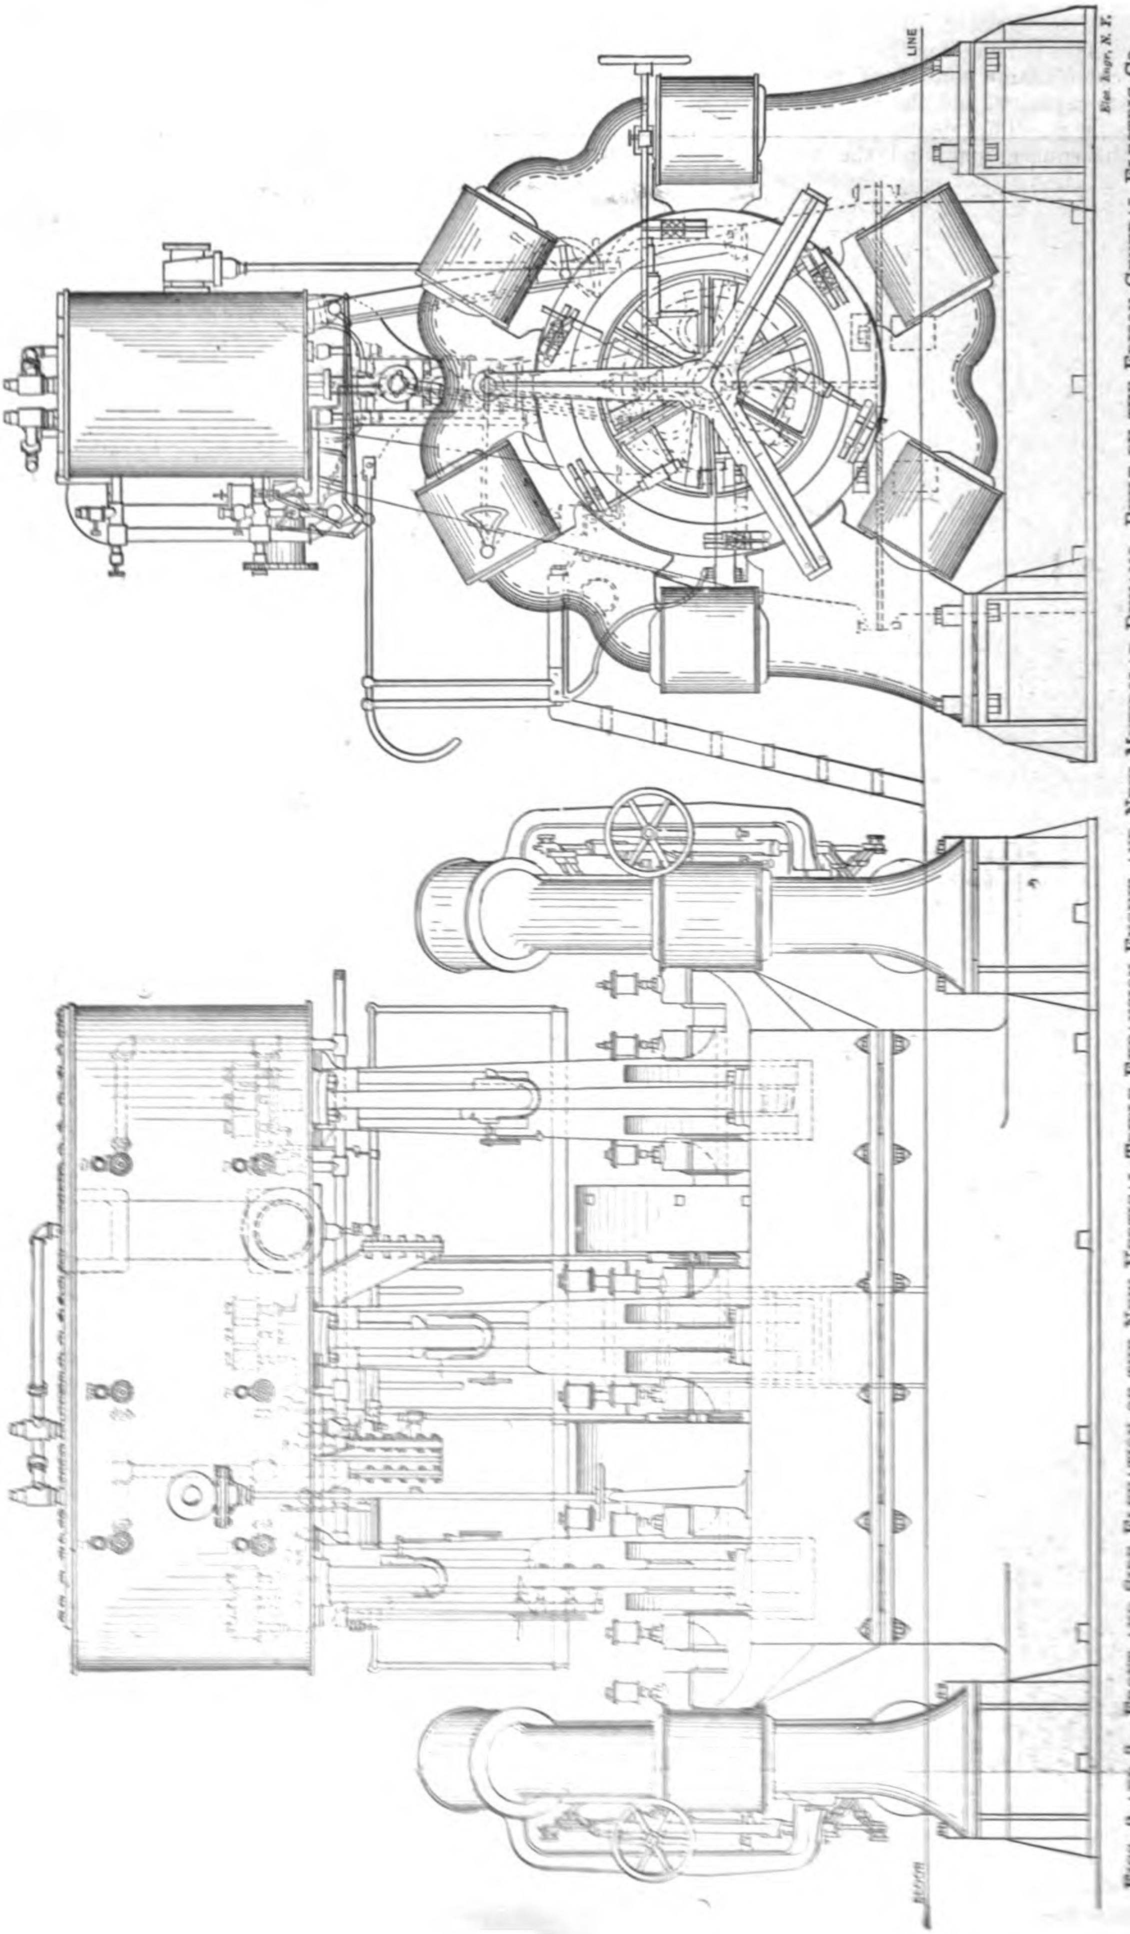


FIGS. 2 AND 3.—FRONT AND SIDE ELEVATION OF THE NEW VERTICAL TRIPLE EXPANSION ENGINE AND NEW MUTIPOLAR DYNAMO, BUILT BY THE EDISON GENERAL ELECTRIC CO.

pany, from which station all the shops included in the works will obtain current for the motors driving the shafting. This combination consists of two dynamos, each of 100 kilo-watt capacity, and the engine capable of working to over 300 h. p. The steam pressure employed is 160 pounds to the square inch, and the three cylinders have the following diameters: high pressure, 11⅞ in.; intermediate pressure, 17½; low pressure, 28¼ in. The stroke of the piston is 21 inches, and the engine and armatures make 176 revolutions per minute, giving a piston speed of over 600 feet. Double ported piston valves are employed, one valve to the high pressure cylinder, and two each to the intermediate and low pressure cylinders. The valves are of hard cast iron, turned and ground to fit hard cast iron bushings secured in the valve chest. Crank shaft governors of special design are employed, and the governors are so arranged that the speed can be adjusted as required. Being designed for central station practice, the lubrication of the engine has been thoroughly worked out so that the engine is adapted for continuous uninterrupted running.

We come now to the generators. In this type, it will be noted, the armature rotates within a field magnet having 10 poles. The frame of the field magnet consists of but a single casting, and a very ingenious method has been designed by Mr. Edison for winding on the magnetizing coils. The Gramme ring type of winding is employed, but instead of using coils of a number of convolutions connected to each segment of the commutator, in this type of machine each convolution is connected directly with the commutator bar. For this purpose bare copper strips of U-shape are slipped over one side of the core, insulated from one another, and each succeeding U-shaped bar of this character is connected direct by a commutator bar. The brushes, it will be noted, bear upon the commutator in a vertical plane. This construction with bare conductors is permissible on account of the very small difference of potential, 1¼ volt existing between each bar. The number of bars employed in this type of machine is 944, and hence an equal number of commutator bars is employed. Each bar is therefore equivalent to a coil of the usual type of Gramme winding, but the absence of contiguous layers entirely avoids self-induction and hence sparking, the machine operating without the slightest indication of such a disturbance. Eight brushes are employed, which can be shifted simultaneously by means of the hand-wheel shown, and which can also be lifted at once from the surface of the commutator. The resistance of the armature is .006 ohm, and that of the field 8.45. Each dynamo is designed for 150 volts pressure and a capacity of 666 amperes. The design has been so well worked out that a variation of ¾ of a load can be made without requiring the slightest change in the position of the brushes.

As stated above, besides the machines already constructed, it is proposed to extend this type over the entire range of available sizes; thus designs are already completed for combinations of 2-25, 2-50, 2-75, 2-100, 2-150, 2-200, and 2-400 kilo-watts, in all of which the triple expansion type of engine will be employed. This type of combined engine and dynamo will probably be employed in the new Edison station in New York, where no less than fourteen 2-400 kilo-watt generators will be placed. In the same way the Cincinnati station will be equipped with ten 2-400 kilo-watt generators. The station about to be erected in Milwaukee for lighting and electric railway purposes will contain five 2x200, five 2x50, and twelve 2x100 kilo-watt generators. At Easton, Pa., three 2-100 kilo-watt generators will be erected. In the power station at the Schenectady works of the Edison Company, above mentioned, there will eventually be erected two 2-50, two 2-100, and two 2-200 kilo-watt generators. The new Edison building in this city will also have two 2-25 generators of this type. It is not difficult to foresee the effect which the adoption of high economy generating apparatus of this type will have on the future operation of central stations. It has long been recognized that greater economy is desirable in station operation, and we believe that the methods above pointed out will place the central station operator at once in a position to obtain the maximum output of current with the least consumption of coal.

RULES AND FORMULÆ FOR INCANDESCENT LAMP WIRING.

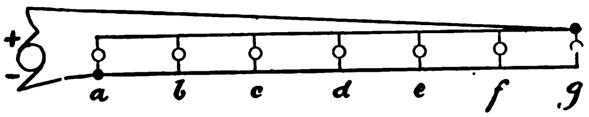
BY

George P. Wardell

The Electrical Engineer for April 15, contains a note by Osborn P. Loomis under this head, correcting an error on the part of Carl Hering, and stating that no system of wiring could be divised which would give the same potential at all the lamps fed by it.

One arrangement, at least, suggests itself which is theoretically perfect, and which would, under some circumstances, be commercially economical. It is as follows:—

In the accompanying figure assume the distance between the lamps *a* and *b* as unity and make the cross section of the positive wire between them the unit of cross section for this problem. Make the positive lead between each pair of lamps, as *e* and *f*, equal to the product of the distance between them into the number of lamps (5) to which it is to carry current, and the negative lead equal to the product of the same distance into the number of lamps (2) from which it is to carry current.



Uniform Pressure on Lamp Leads.

HYDROCHLORIC ACID IN BICHROMATE BATTERIES.

BY

Chas. J. Reed

In The Electrical Engineer of April 22nd, Mr. Chas. Steinmetz advocates the use of hydrochloric acid in bichromate cells. Permit me to call attention to the chemical reactions that must take place.

It is well known that hydrochloric acid or any soluble chloride added to an acid solution containing chromic acid or any soluble chromate, reduces the chromate to a chromic salt with evolution of free chlorine and water, as in the following equation:

$$2H_2CrO_4 + 12HCl = Cr_2Cl_6 + 8H_2O + 6Cl.$$

If sulphuric acid is present in sufficient quantity, only half the amount of hydrochloric acid in the equation will be required, and chromic sulphate or a chrome-alum will be formed. The chromic salts formed in a battery are all inert (so far as zinc and nascent hydrogen are concerned), waste products. The only advantage that can result from the use of hydrochloric acid is the evolution of chlorine at the expense of the chromic acid. The advantage of free chlorine in a battery seems to me doubtful, and its preparation by the action of a chromate on a chloride is, at least, expensive.

THE SOLUBILITY OF MIXTURES OF ELECTROLYTICALLY DISSOCIATED SUBSTANCES.

The principles which regulate the influence of two salts upon the solubility in water of each other are those which can be deduced from the general law of mass action as interpreted in the light of the electrolytic dissociation theory; this has been demonstrated by Nernst, and the subject has recently received further attention from A. A. Noyes, another German chemist. Eleven pairs of salts were carefully examined, and the results of the experiments seem to show a very fair agreement with the values deduced from theory. Most of the investigations were carried out with binary electrolytes, but a few tertiary electrolytes were shown to yield results equally in harmony with the theory. Experiments were made not only with pairs of salts containing one ion in common, but also with pairs of salts the ions of which were all different. Noyes considers that reckoning back from the solubilities it is possible to calculate the dissociation constants of strong electrolytes. If this is a fact, it is one of considerable importance, for the ordinary method of calculation from the electrical conductivity fails in such cases to give a constant number at all. The details of the experiments and the results, etc , for the 11 pairs of salts examined are given in full in the original paper for which pages 241—267 No. VI. of the *Zeitschrift für Physikalishe Chemie* must be consulted.

SUPERIMPOSED MAGNETIZATIONS.

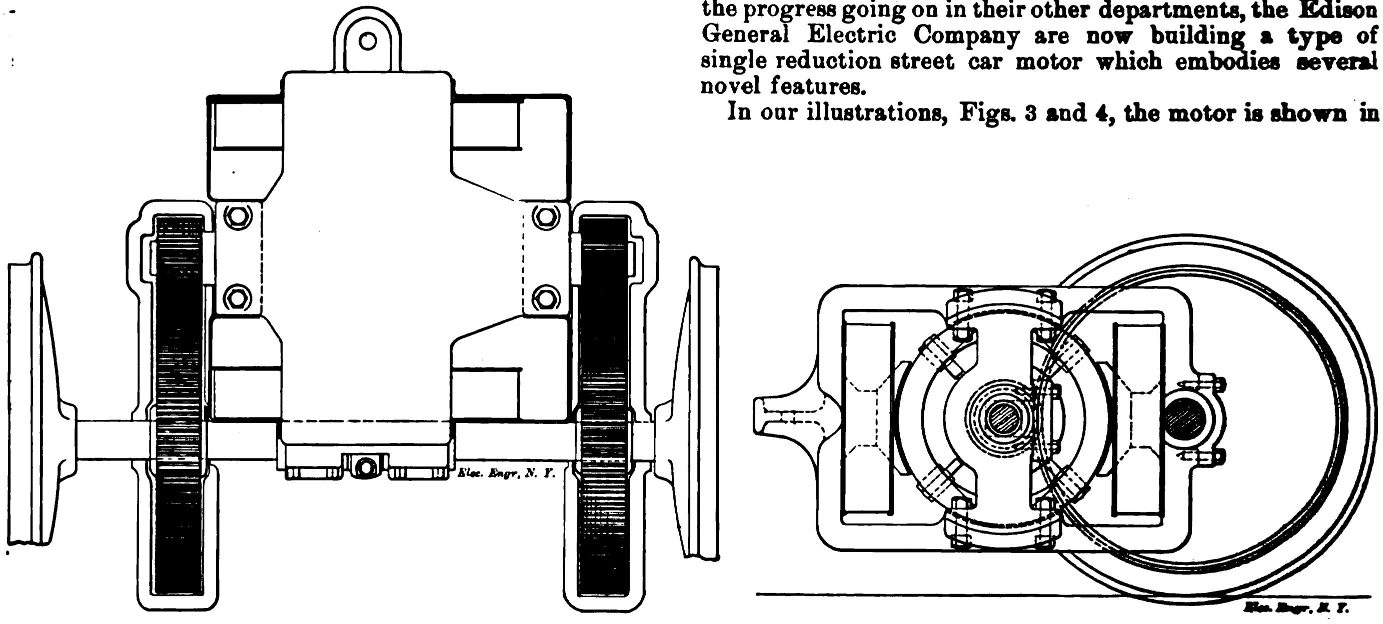
Experiments by M. Jamin have shown that two longitudinal magnetizations of inverse polarity may be imposed on a piece of steel without mutual neutralization. The same has been shown by M. Decharme to be true for transverse magnetization; and in a recent communication to the Académie des Sciences, M. Decharme describes the result of magnetizing the same piece of steel successively, longitudinally and transversely. The specimen of steel was 100mm. long, 28mm. broad, and 3mm. thick. If the conditions were favorable and care was taken, it was found possible to obtain an iron-filing sketch, showing two simultaneously existing magnetizations. In most instances, however, the two magnetizations were merely superimposed, and by making the proper passes the longitudinal and the transverse magnetizations could be made to predominate in succession, and with increasing strength, until saturation point was reached. A bar magnetized first longitudinally and then transversely, would thus appear to be in a state of magnetic instability.

THE EDISON NEW SINGLE REDUCTION STREET CAR MOTOR.

Although the application of the high speed electric motor conveying power to the car axle by a double reduction gear has demonstrated beyond question the practicability and economy of electric railroading, it has become evident that improvement could be effected by the elimination of some of the gearing heretofore employed. The modification necessary to accomplish this purpose, readily suggests itself in the reduction of the initial speed of the motor and the employment of a single reduction only between the motor and the car axle. As the power of the motor is the product of the torque into the speed, the application of the slow speed motor necessitates a construction such that the torque of the motor shall be increased in the same proportion as its speed is reduced. This is best carried out in the multipolar machine, and in keeping with the progress going on in their other departments, the Edison General Electric Company are now building a type of single reduction street car motor which embodies several novel features.

In our illustrations, Figs. 3 and 4, the motor is shown in prospective as seen from either end of the armature, the gears being removed from the shaft in Fig. 3 in order to expose the commutator and brush arrangement. The more detailed construction of the motor is shown in Figs. 1 and 2, from which it will be seen that the machine is of the four-pole type and practically iron-clad. Only two poles, those in the horizontal plane, are wound, the two in the vertical plane being magnetized by induction from the same spools and forming, as it were, consequent poles of opposite polarity. The entire field, consisting of special soft cast-steel, is made in one casting with the exception of the pole pieces which are attached by screw bolts after the spools have been slipped on over the straight cores at the sides. These pole pieces, it will be noted, extend for a short distance beyond the field coils, and practically 80 per cent. of the whole spool is surrounded by iron. As a result of this construction and the employment of cast-steel, the magnetizing force required to attain the proper degree of magnetization is small, and from the nature of the construction there is very little stray magnetism.

The magnetizing coils are wound in three sections on vulcabeston spools, which, as stated above, are slipped on over the cores. In the construction of the machine the facing of the armature bearing and the cylindrical arma-



Figs. 1 and 2.—Side Elevation and End View, Edison New Single Reduction Street Car Motor.

ture space are bored out at one boring, and by loosening two bolts the armature can be slipped out completely, so that inspection can be effected with great facility. The armature, which is of the Gramme type, is built up of punched soft iron rings insulated from each other, and with the end plates of wrought iron and bevelled. On the interior diameter of the hollow cylinder built up in this manner, there are four grooves placed 90° from each other, and into these grooves the aluminum-bronze spiders are pressed by hydraulic pressure, two spiders being employed and bolted together. In this way a firm mechanical connection is made between the armature shaft and the ring.

The diameter of the armature is 18 inches, and its length 13 inches. The shaft is 3 inches in diameter, and upon each end is mounted a pinion which meshes with the large gears at each end of the axle, thus equalizing the power on the axle. One end of the magnet forms the car axle bearing and the other is suspended by a spring at the nozzle for easy starting, The commutator has been made specially large, being 10 inches in diameter.

The armature is wound in 140 sections, and on account of the strong field employed, and the method of connection to the commutator, no spark is observed. The winding is put on in one continuous length of wire, and at each section a tap wire of German silver is taken to the commutator. The object of employing a German silver wire will become obvious when it is pointed out that, as is well known, the brush in passing from one commutator segment to another short-circuits the coil between them for an instant. The introduction of the German silver wire with its increased resistance reduces the current induced by the short circuit considerably, and, hence, the sparking due to that cause; and it also aids materially in cutting down the current, if by any accident the motor should be accidentally short circuited. It will be evident, however, that in the operation of the machine only those two German silver wires are in circuit which lead from the commutator segments immediately under the brushes, all the others being, of course, without current during the period between their travel from one brush to the other; hence, although the introduction of these two short lengths of German silver wire has no appreciable effect upon the normal operation of the armature it affords a simple method of avoiding sparking and danger from short circuits. The entire machine is encased in a water-tight cover, and its total weight with gears is 2,200 pounds. The machine is rated at 25 h.p., but will readily develop 30 h.p. It is intended to apply two of these machines to each car of the double truck type, while one machine alone will be ample to drive the smaller cars. The motor is of the series type and the regulation is effected by varying the combination of the fields, which are wound in three sections. By this method of regulation the use of a rheostat is avoided.

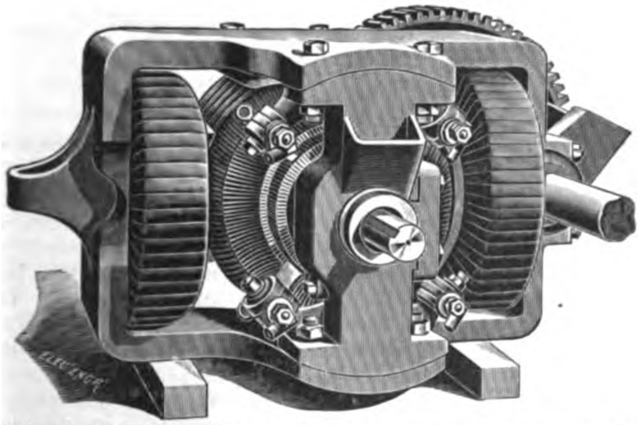


FIG. 3.—THE NEW EDISON SINGLE REDUCTION STREET CAR MOTOR.

The four carbon brushes employed are rigidly fastened to the frame and require no shifting throughout the range of load to which the motor is subjected. The motor is calculated to revolve at 460 revolutions with the car running at a speed of 12 miles an hour.

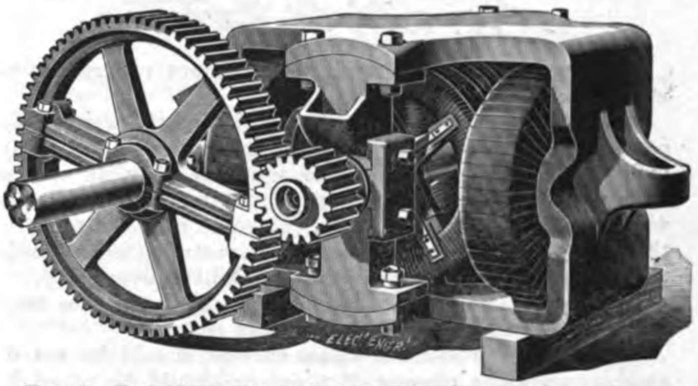

FIG. 4.—THE NEW EDISON SINGLE REDUCTION STREET CAR MOTOR.

It is also contemplated to construct immediately a 15 h.p., single reduction iron clad motor of the same type for lighter work.

THE WAVE-LENGTHS OF ELECTRICAL OSCILLATIONS.

In repeating the classical experiments of Hertz upon the wave-lengths of electrical oscillations, H. K. Waitz, has arrived at the following conclusions, namely:—(*a*) A discharge of an induction coil of a definite species excites oscillation of different wave-length, which may extend over an interval of many octaves. (*b*) Amongst these electrical oscillations there is one of greater intensity, the wave-length of which is determined by the dimensions of the conductors. (*c*) The electrical oscillations in or upon conductors change their wave-lengths when the medium surrounding the conductor changes.

THE THEATROPHONE.

THERE was founded last year at Paris, the "Theatrophone Company," the object of which is the institution of a telephonic theatrical service. The company has erected in the various public places, such as cafés, clubs, restaurants, etc., a certain number of automatic telephone receivers by which, on introducing a fifty centimes piece, one is placed in communication, for five minutes, with theatres or concerts indicated on the apparatus. At present the Opera Comique, the Bouffes, and the Nouveautés are the only theatres in connection with the system, but the number will be soon increased. The Theatrophone Company intends to supplement this public service by a private service, available for all subscribers to the State telephone system. By means of the monthly subscriptions of fifteen francs, and a payment of fifteen francs per evening for this service, a subscriber to the Paris system can enjoy telephonic communication with a given theatre, selected from among those connected with the service, during the entire performance, and for any number of listeners. The prices given above are for two receivers. The addition of extra telephones, so that several persons may hear at once, entails a further charge of two francs per pair per month.

THEATRICAL ELECTRICIANS.

Since the introduction of electric lighting into nearly all the theatres of the country, it has been found necessary to add an electrician to the corps of assistants. He is not necessarily an expert in the scientific sense, but he must know how to repair any sudden breaks or interruptions, and be able to control the lights sufficiently to answer the purposes of the play. The electrician traveling with the "Poor Jonathan" company gets $20 a week.

CENTRAL STATION MANAGEMENT AND FINANCE.—II.

BY

Horatio A. Foster

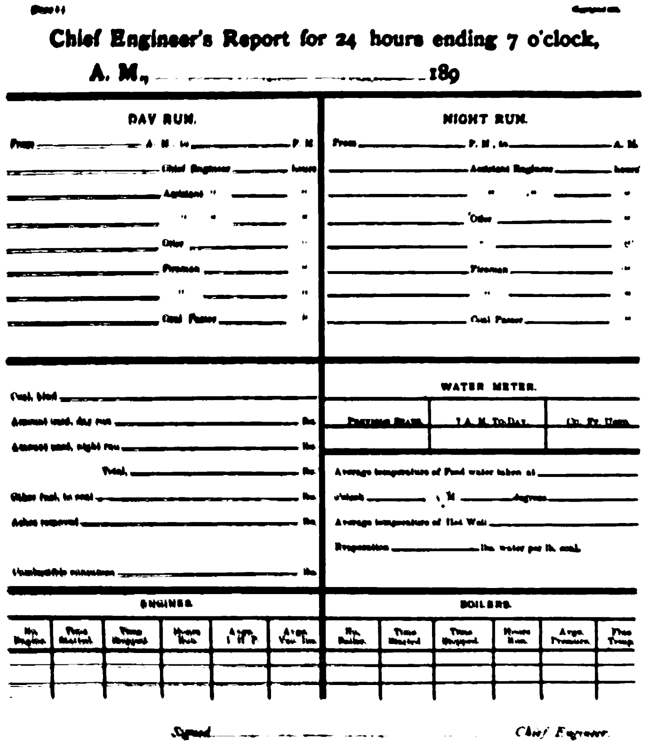
We next take up the regular department reports, commencing with the boiler room.

This sub-department is, in the opinion of the writer, one of the most important of all, as great waste is so easily made if firemen are careless or ignorant. By all means have the best fireman that money can hire, as he is the man who shovels away your dollars. The data required to show the condition and efficiency of this department is so simple that it is folly not to have the items at hand every day.

Each boiler should have its number which must be used in all references to it for conditions or repairs.

The average pressure of steam carried, should be noted, and any irregular change of pressure should be noted in remarks.

Some engineers keep a regular log, recording the pressure of steam, etc., every half hour or hour; this is not deemed necessary by the writer, as all modern steam plants are provided with a good damper regulator which will easily keep steam pressure even throughout a run. A good recording gauge is a very handy instrument for use in the larger stations, and is always a good check on the motive power department.



Chief Engineer's Report for 24 hours ending 7 o'clock,

BOILERS.

No. Boiler.	Time Started.	Time Stopped.	Hours Run.	Avge. Pressure.	Flue Temp.

Signed ______ Chief Engineer.

BLANK NO. 2.—CHIEF ENGINEER'S REPORT.

The amount and kind of fuel fired should be noted, stating in the remarks column any particulars as to quality, that are expected to be noted by officers in charge. Where part wood is used, and it is desired to reduce it to coal equivalent, it is only necessary to multiply its weight by .4, which gives the equivalent in lbs. of coal. The weight of ashes and clinkers removed should always be recorded, as the percentage of waste in fuel indicates the quality.

The amount and temperature of feed water is also very important. The first, when compared with the amount of fuel consumed, gauges the evaporative efficiency of the boilers. The only convenient way of recording this is by some good meter. The dial reads in cubic feet, which is reduced to pounds by multiplying by 62½.

It is necessary to know the temperature in order to reduce the evaporation to a standard, as, say, from and at 212°. A handy and cheap way to take it is to have a ⊥ inserted in the run of the feed pipe, close to the boiler. A plug with a ⅜ inch brass tube with its bottom end plugged is screwed into the side opening. This tube is filled with cylinder oil to hold the heat, and the temperature can be taken at any time by putting a small thermometer into the oil.

The names and time of all employés are all that are necessary to give the expense, supplies being given by the storekeeper and only placed on the weekly or monthly report. Blank No. 2, report of chief engineer, has space for all the data mentioned above. The same blank also has space for the necessary data for the engine room. This data includes the numbers of engines run, with the time of starting and stopping them, and, where possible, the average indicated horse-power. Where engines are used on the same machines—and changes are seldom made—if half hourly cards are taken for a few nights running, and the average load is figured for them, then cards taken on the same engine at the hour which was found to agree nearest with that average load will be approximately correct. This will be more so if taken on or about the 21st of March or September, which is the average time for the year.

Where condensing or compound engines are used, it is well to record the average vacuums. If vacuum varies much, the fact should be noted in "remarks" and the air pump and condenser should be overhauled.

In the space left for remarks should be entered full details of all work done out of the usual routine, such as washing out boilers, repairs on fire boxes, engines, pumps or other work.

A good chief engineer will find plenty to do to keep the motive power department up to the best conditions of efficiency. As a general thing, more trouble and waste takes place in this department than in the electrical, and largely from the fact that few station managers understand the advantages of employing a good chief engineer.

OHMTOWN AND VOLTVILLE—"A TALE OF TWO CITIES."

BY

G. T. Evans.

Ohmtown and Voltville, according to the last census, are almost equal in population—but the similarity goes no further. Ohmtown is surrounded by a fence of fogyism and penny wisdom—Voltville lives in an atmosphere of shrewd enterprise. Ohmtown reaches out her hand for improvement with as much trepidation as the little boy does for the school strap, she is uncertain about the amount she wants and comes away with a meagre fistful and a sense of offended economy. But Voltville—and she believes in economy, too—though not in the kind which paves a street twice in three years at $1,000 a job when a $1,500 job will last ten years—has an eye elected by public opinion to keep a watch for what may improve the town. If such an object is seen, and after mature deliberation is deemed necessary, all the energy of the people is concentrated to get the best of the kind at the cheapest price. In fact, the paradox "Best and Cheapest" is the aphorism of the town.

A few years ago the electric fever struck each of these places. Voltville had it heart, mind and body, but Ohmtown had a slight superficial attack. The rich Mr. Impedance was elected president of her company. He and the directors possessed the characteristics of the town to an exaggerated degree, so the quality of the new electric plant was an easy thing to foresee. Arc lights were to be used for the streets, and for the sake of economy it was decided to have them about three times further apart than is the ordinary practice. Thus the arc capacity was estimated. Then for the incandescent system a local investigator was sent out to discover how many lights would be taken. Tom Brown, the baker, said he would not have the dangerous stuff in his shop. Mr. Reluctance, the dry goods merchant, thought probably he would not, and so, the investigator, obeying the teachings of the town, left off from his list the names of Messrs. Brown and Reluctance together with some hundred of their brethren, and made his report to call for about half the number of lights an experienced solicitor would have estimated on and secured contracts for. Thus was the incandescent capacity calculated. And knowing so exactly the amount of power required, the contract was let for a station building just large enough to hold the machinery. No extra room was wanted; Ohmtown abhorred a space. The electrical public were soon informed of the intentions of Ohmtown, and the kind of work that was required. Bids were sent in accordingly. The Rush and Shiftless Construction Co., though closely pushed by the Cheapest, finally secured the job, being able to beat the latter by furnishing a quantity of wire that had already served a term of years elsewhere. And Ohmtown was delighted with her bargain—overjoyed when the second-hand boiler came; and she expatiated on the strength of its numerous patches. And the engine was a beauty though it had run a sawmill for a generation. But great is paint! In the infancy of dynamo building, the second-hand dynamos that Ohmtown bought would have been considered wonderful. Ohmtown thought they were now, but Ohmtown didn't know much about efficiency. Yet, with all the self-satisfaction of Ohmtown, no one praised the pole line. Before its arrival Ohmtown was not an extremely bad-looking city, but after—well, poles that "belly" to every point of the compass and look as if some gigantic Indian had used them for bows are not conducive to beauty.

Voltville had, of course, proceeded on entirely different lines. Ohmtown would have lifted up her hands in horror and hung the flag of Economy Hall at half-mast if she had seen the first act of Voltville. An electrical expert was sent for. Now electrical experts don't work for fifty cents per day, but they earn what they get, and Voltville found that out as time went on. Mr. Accuracy, E. E., made a long study of Voltville; its shape, size, peculiarities and tone of its people. Then he made public his plans. He stated what system would best suit Voltville, how many lights should be arranged for—in short, he gave points on all the main details, and reasons for each. His plan was an expensive one to carry out, but was in conformity with Voltville's motto. The Rush and Shiftless Co. didn't get this contract. Its bid was below that of the Stability Co. but the Stability got the job. The reputation of the Rush and Shiftless concern had not been helped by work of the Ohmtown pattern.

Voltville had reason to be proud of her new industry; the station building was large and had plenty of spare room. The boilers, engines and heaters were modern and built to save coal—the steam pipes were covered for the same reason. The electrical machinery was the best to be had from a responsible manufacturer. A traveling chain tackle was in place to save valuable time, and it was saved too. Armatures didn't burn out often, but when they did there was no running about after a rope and pulleys and half a dozen men. This was Ohmtown's plan. Voltville had a very respectable looking pole line. In the central part of the town iron poles were used, and the wooden poles were straight, were stepped and painted, and their butts treated with waterproof compound. They were intended to last. First-class wire was used throughout. Voltville couldn't afford to buy coal to supply leaking circuits.

Ohmtown's lights, when the station was started, were very good considering the motion of the saw mill engine, but there were obviously not enough. Tom Brown and Mr. Reluctance and their doubting friends found now that they wanted lights and sent in applications. More arc lights were necessary. The station was already worked to its capacity. Sheds were added—more second-hand machinery of various types was bought, and the coal melted and melted. Inefficient machinery has a great appetite for coal. Voltville is to-day paying dividends on her electric investment. Owing to Mr. Accuracy's forethought, there is still room in the station. A power circuit for stationary motors is worked, and preparations are being made to supply current for an electric railroad. The superintendent is a follower of Mr. Accuracy. He is competent, and Voltville is sensible and pays him a living salary.

Ohmtown *may* pay a dividend sometime. Her station now resembles a village of additions. The stockholders' pockets are being picked for repairs on the apparatus. The wisdom of the directors endeavors to help matters by cutting down help and wages. The superintendent (?) is a man of all work. He is expected to string wires, climb poles, dig holes and shovel ashes, for $1.50 per day. He is a willing, anxious fellow, but he succeeds no more in doing his various duties than the distressed hen struggling to cover 15 or 20 half-grown chicks with her wings.

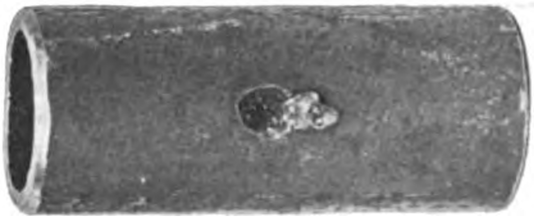
Is local electric lighting a failure? Ohmtown answers a dismal "Yes." Voltville points to her swelling pocketbook.

AN INSTANCE OF CARELESS WIRING.

BY

C. J. H. Woodbury.

The accompanying engraving, reproduced from a photograph, represents a piece of an automatic sprinkler pipe in a mill, with which an electric wire on a circuit used for incandescent lighting was in contact, and against which it chafed by the jar of the mill until the insulation was abraded. The circuit was grounded, and the diversion of electricity was sufficient to fuse a small amount of the iron, which cooled at the side of the depression. The pipe was perforated with an orifice about one-sixteenth of an inch in diameter, out of which the water in the sprinkler system issued, and this first called attention to the accident. This is only one of many incidents showing the great importance of maintaining an actual separation between electric lighting apparatus and iron piping.



THE RESULT OF CARELESS WIRING.

TACOMA, WASH.—The officers of the Commercial Electric light and Power Company, recently elected, are as follows: President, George Browne; vice-president, M. G. Denton; treasurer, Chester Thorne; secretary, Robert Sale Hill; directors, C. W. Griggs, D. P. Newton, George Browne, M. G. Denton and Chester Thorne.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, APRIL 29, 1891. No. 156.

Every material operation and every invention is founded on some law of nature, and the more intimately the operator is acquainted with the principles of his art, the more fitted he is to improve it.—Joseph Henry.

A NEW DEPARTURE IN CENTRAL STATION ENGINEERING.

A SUCCESSFUL central station manager once remarked that the commercial success or failure of an electric central station depended upon the management of the coal pile. It is obvious that for economical operation the central station must be arranged in the light of the most modern practice, not only in electrical but in steam engineering. It may be looked upon as a well established fact that the best results are obtained in central station practice by the employment of units of power both in generator and dynamo, these units, of course, to be adapted to each special case, and depending upon the amount of current distributed from one centre. The size of the unit once being determined, the next question is the manner in which these units shall be operated. Although a great deal of discussion has been carried on as to the relative superiority of high and low speed engines, there can be no question as to the great advantage, in many respects, of direct connection between engine and dynamo, and if to this be added a construction of dynamo such as will be adapted to an engine of known high economy, the best practice in the light of present knowledge will have been attained. The recent improvements which have been made in steam engineering, especially in the triple expansion engine, render this type eminently fitted to central station practice, and when directly connected to a dynamo specially adapted for the speed which can be attained from such engine, the economy must of necessity be high. Taking this view of the case, evidently, the Edison Company have undertaken the most decided departure in practice in this country, and our description on another page of the new vertical triple expansion engines they are building, and their new direct connected generators, will be read with interest, especially by central station managers. The experience which has been gained abroad in the employment of this type of combined engine and dynamo is such as to fully warrant its continued application, and it is not too much to say, we believe, that the large central station of the future is destined to be run upon the new methods now indicated.

It is evident that a further stage of development is now reached in large central station work, and that the production of current by these large generators puts electric lighting at once on a parity with gas. With the cost of the two illuminants the same to the consumer, there is no question as to which light he will choose.

URBAN POPULATION AND ELECTRICITY.

A VERY interesting bulletin just issued by the Census Office gives the growth of urban population in the United States. It shows that if there be included in the urban population all communities down to a limit of 4,000, that population reaches 18,235,670, out of a total of 62,622,250 or 29.12 per cent., or an increase of nearly 7 per cent. over 1880. The same fact is even more strikingly brought out in the statistics of cities over 8,000. Of such cities there were 286 in 1880; to-day 443 are to be found, or an increase of 50 per cent.

The decade that has witnessed this amazing growth—a growth that Mr. Porter is gravely accused of understating—has seen also the rapid introduction of the electric light, and to-day there are very few towns even down to the 4,000 limit that are not familiar with the cheering beams of the silvery arc. A large proportion also of the cities of 8,000 population enjoy the rays of the golden incandescent, but it is evidently here that a great deal of work remains to be done, in so far as the extension of electric lighting is to maintain its higher rate of increase as compared with the rate of urban centres.

When we turn to the department of electric railways, the field reveals itself as still one of large opportunity. In other words, we can still haul in a good deal of slack before settling down to a normal rate. The electric light is an old story to-day in many a town that has never had even a horse car, but which now is anxious to catch up by the immediate adoption of electric cars. But it might be said, as was said recently by an electric engineer, that this work of exploitation would reach its end in three years at the rapid pace now being made. There is, however, an abundance of work beyond, not only within the cities but outside them and in the new towns; and we expect that the census returns of the year 1900 will exhibit the effects of electricity in its application to the "commuter" service around all the large cities. It would be hardly going too far to say that in a few years every traveled road will be made a railroad by the presence of an electric track along it.

Another interesting, but less complete, return, published by Superintendent Porter last week, dealt with the relative economy of cable, electric, and animal motive power for street railways, covering statistics of fifty lines, ten operated by cable, ten by electricity, and thirty by animal power. The figures show : Total cost of cable roads, including equipment, $26,351,416 ; passengers carried, 101,995,695, at a cost of $3,286,461 ; operating expenses per car mile, 14.12 cents ; per passenger, 3.22 cents ; length of tracks, including sidings, 143 miles. Total cost of electric roads, $2,426,285 ; passengers carried, 8,031,214, at a cost of $326,961, or 13.21 cents per car mile and 3.82 per passenger ; total track mileage, 67.22. Total cost of animal power roads, $22,788,277 ; operating expenses, $6,986,019 ; passengers carried, 190,434,783 ; expense per car mile, 18.16 cents, and per passenger, 3.67 cents ; miles of track, 552. Nine of the electric roads quoted were operated by the trolley system and one by the storage-battery system. Even on this limited basis the comparison is favorable to electricity, and it becomes more and more so as the new roads with improved mechanism go into operation. While Mr. Porter was digesting these figures, the electric roads were increasing in the single year 1890 from 160 to 281, although street car companies increased only 5 per cent., and not one of those roads had by any means reached its point of highest economy and efficiency. One could hardly expect immediate perfection in so new an industry.

THE VALUE OF "GUARD WIRES."

In a recent issue we took occasion to comment on the situation at Albany, N. Y., where the troubles at the telephone exchange have been attributed to the absence of guard wires. Mr. W. H. Cull, of the electric railway in that city, stated through our columns his belief that guard wires were not always an unmitigated blessing, but were sometimes a danger in disguise. We are now able to give some more definite data on the subject. Mr. C. C. Upham, of the Salt Lake City roads, furnishes this week a summary of the replies received to a circular of inquiry on the point in question. His article shows that the value of the guard wires as a means of protection to the public has not yet been fully established. The fact is the guard wires are not much stronger than the fragile telegraph and telephone wires with which the trouble begins. Some day, perhaps, somebody may invent an electric railway conductor with a pent roof that will shed safely all the rusty and rotten wires that fall upon it, but until then, it does seem only reasonable to try to protect with fuses, electrical apparatus liable to be smitten. Even if there were no railway circuits, this precaution would still be eminently proper.

THE EDISON SINGLE REDUCTION STREET CAR MOTOR.

The description which we give in this issue of the new Edison single reduction street car gear, while interesting in itself as showing the change which is rapidly going on in the methods of electric railway operation, also serves to draw attention to the changes which have been gradually made in the methods of construction, and the materials employed in street railway motors. Thus it will be noted that the Gramme armature is now finding employment where formerly the Siemens ring was almost exclusively used. The simplicity of the Gramme ring, the thorough independence of each coil from its neighbor and the ready manner in which it can be repaired, together with its adaptability for slow speed work, make it probably the form best adapted to this purpose. Another important feature is the employment of soft cast steel for the magnetic frame of the machine. Experience has show that the permeability of this material is little, if any, less than the best wrought iron, and the readiness with which it can be fashioned into the required shape by casting must at once stamp it as a most valuable addition to the working materials of the electrical engineer.

CURRENT CONSUMED BY ELECTRIC MOTORS.

The manufacturer of motors, not less than the user, is always interested in the quantity of current consumed in motors, as upon this point the efficiency, and hence the cost of electric power depends to a large extent. The table we give in another column, prepared by Messrs. Crocker and Wheeler, will therefore find a useful place wherever electric power is applied. It will be noted that the table has been calculated on a very reasonable basis, the motors of the smaller powers, especially, being taken at an efficiency which certainly brings any calculations based upon the tables within conservative limits. For the same reason the arc motors are taken at a somewhat lower efficiency than those designed for constant potential circuits. Dr. Wheeler also points out an interesting fact which is generally overlooked. He shows the advisability of careful consideration in the selection of the size of motor, which should be taken rather above the estimated power than below it, since the motors of larger size have a higher average efficiency than those of less power. . Besides this, however, it is always advisable to have a certain amount of power in reserve which can be called upon in an emergency without endangering the life of the motor.

Electric Railroading in California.

As our Electric Railway Notes show, there is considerable activity in electric railroading in California ; in fact, it might fairly be called a "boom." This pleasing condition of things is due to a change in the law, as until recently the use of electricity as a motive power for street cars has not been legal. Mr. J. W. Hartzell, manager of the San Francisco & San Mateo Railway Co., to whom we are indebted for a copy of the bill, expresses his belief that there will be a great many new roads in the near future. This is, as he says, an important item of news for Eastern people interested in electrical apparatus and supplies. We are glad to note the new opening for engineering and trade. It is not unlikely that local electrical manufacturers in the State may also be stimulated and benefited by these favorable circumstances.

THE USE OF "GUARD WIRES" ON ELECTRIC RAILWAYS.

BY

Chas. H. Clapham

Some time since, the telephone people of Salt Lake City petitioned the City Council, praying that the street railway companies be required to put up guard rails over the trolley wires. The matter was referred to the committee on streets, and has not yet been acted upon.

The Salt Lake City Railway Company and the Salt Lake Rapid Transit Company sent out circulars of inquiry on the subject to some 40 electric railway companies in the country. These circulars brought answers from 28 companies, who reported all sorts of experiences. These experiences indicate that the greatest amount of doubt exists as to the value of guard wires.

There seem to be out of 28 companies answering, 18 that use guard wires and 10 that do not use them now; 13 put them up voluntarily, and seven at the direction of municipal authorities. Seventeen put the wires up at their sole expense, while two divided cost with telephone companies. Four companies put up the guard wires to protect the public, eight to protect the overhead wires, four to protect all interests, and three in self protection. Twenty-two companies used span wire construction, three centre pole and three both methods.

Nine companies state positively that the guard wires have answered the purpose; six answer as decidedly that they have not, while five are doubtful. Sixteen companies still have the wires up, while three have taken them down. Out of the 28 companies, nine recommend the use of guard wires; seven do not recommend their use; two recommend them in some places, that is, at street intersections; two are doubtful, and eight have had no experience with them.

An official of one of the metropolitan companies, in fact, one of the largest companies in the country, writes: "In my opinion the guard wires are an additional source of danger, both as regards fire and the public, and it would be far better if additional precautions were taken with the other wires, such as providing them with fuses where they enter buildings so that in case of contact there would be no danger of fire, and thus doing away with guard wires entirely. I find this opinion held also by many other electric railway men." An official in one of our large western cities writes: "Three days since, a broken guard wire carried the current so as to strike a passing team, killing both horses." Another writes, "Almost all electrical disturbances have been caused by guard wires coming in contact with other wires."

Another company do not recommend the use of guard wires but put them up "because they are recommended by the electrical company whose system we are using." A southern railway official says: "All guard wires have been taken down because they were constantly breaking and causing trouble in the street. There has been practically no complaint since removed." Another company still has the wires up but does not recommend their use, because "when any wires are down they increase the trouble and never stay where placed." An Eastern superintendent has taken down his guard wires, "because of no special benefit."

It would seem from all this testimony that the use of guard wires is not an unalloyed blessing.

UNFORTUNATE ILLNESS OF A DISTINGUISHED FOREIGNER.

The *New Haven Journal* says gravely that during a test of an electric car in that city recently, the "Rheo Stadt" gave out! The cause of this gentleman's collapse is not positively known, but it is supposed to be due to current jam.

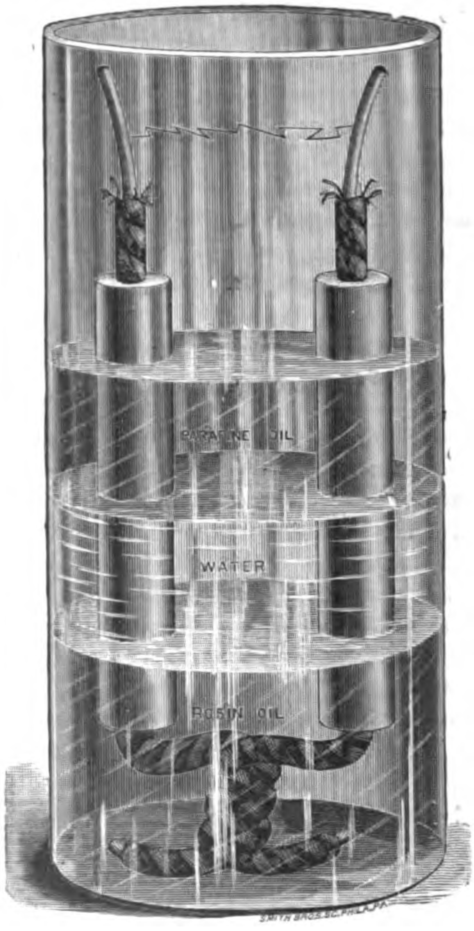
OIL AS AN INSULATOR FOR HIGH POTENTIALS.—I.

BY

David Brooks

There is much more written about the uses of oil for electrical purposes now than ten years ago and not referred to, as then, as "oleaginous nonsense." Following up the note of mine in the preceding number of your journal, I immersed a small induction coil called "Shocking Machine" in oil and increased the inductive effects to such an extent that, with the plunger withdrawn, no one could bear the shock. I took it to two makers of those instruments and neither of them cared to make use of the improvement because, by the use of the plunger, sufficient effect could be produced that any person desired to bear.

The effect was greatly increased when I discovered the properties of rosin oil. Although I had tested rosin oil earlier, I could not make near as much out of it as of paraffine oil, for the reason that ordinary rosin oil has about the same specific gravity as water and held water in suspension. But when you come to heat rosin oil and drive out the moisture its insulating properties are immensely increased and the distillers are able to make an oil that is far heavier than water or even heavier than sulphuric acid or any other liquid that I have ever experimented with, unless it be quicksilver.



An Experiment With Oil Insulators.

The accompanying illustration, shows an experiment that was exhibited at the Electrical Exhibition in Philadelphia, in 1884, nearly seven years since. It was labelled "THE ELECTRICAL POUSSE CAFÉ." It will be observed that when the wires are disconnected, a cover can be placed over the jar to keep out the dust. I have that jar to this day, and have never been able to spark through the covering of the wires where they are twisted together, as shown, in the oil. The glass tubes prevent the spark from going through the water.

Now, I beg the reader to consider what advantage there is in having an insulation that is heavier than water and is not penetrated by it, or does not absorb it. How many hundreds of thousands of dollars' worth of gutta percha or India rubber insulated conductors have failed within the past ten years on account of the access of moisture to the conductor? Not immediately, but in time, the insulation disintegrates and decays, becomes spongy, or contains fissures. The first oil-insulated cable that was laid for practical use on my system was in London, in 1880, eleven years since. I then used paraffine oil and they had trouble in keeping it in the pipes. As soon as I found out the virtues of rosin oil I sent them a number of barrels of it and since that was introduced they have had no trouble.

The London *Electrical Review* recently contained a series of articles entitled "Storms and Telegrams," by Messrs. Slingo and Brooker. They state as one of the advantages of the oil system that if the insulation is punctured by atmospheric electricity the oil soon closes up again the puncture, and that, to use their words, "it is self-sealing"; bringing that feature into consideration, in connection with the fact that the oil is heavier than water, it is worthy of note that, since the introduction of the rosin oil, of the many thousands miles of conductors that have been laid, for telephone, telegraph and electric lighting purposes, not a single interruption has occurred to my knowledge.

I had forgotten entirely that I had obtained a patent for the use of oil in induction coils until I read the article on "Experiments on the Transmission of Power at Very High Potentials,"[1] and I do not know that I can say much more in its favor than is stated by Mr. C. E. L. Brown and by Prof. Thomson.

Not two weeks since, I was experimenting in the laboratory of Mr. Carl Hering with the Holtz machine. We twisted two No. 18 wires covered with paper to a thickness of a No. 8 gauge. There was a great deal of brush leakage between the two wires above the oil, so we placed a glass tube over each to cover the wires close up to the poles of the machine. To keep the glass tubes in position we laid a wire across the top of the jar and then went on sparking between the two spheres until we had them separated 4¼ inches. Separating them a little farther the spark went through both glass tubes to the wire on the top of the jar supporting them in position. Warren de la Rue and Hugo W. Müller give the electromotive force of a 4 inch spark between a point and a disc as 93,500 volts; but this 4¼ inch spark was between the two spheres, which is much harder to accomplish than between a point and a disc.

THE USE OF THE GOOCH CRUCIBLE AS A SILVER VOLTAMETER.

In order to avoid loss of silver by the washing of the deposit in a voltameter, M. Lœb recommends the use of a modification of the well-known Gooch crucible:—A rather tall and narrow platinum crucible having a perforated bottom is fitted into a glass cup terminating in a syphon. The two are united by means of a piece of India-rubber tubing which should be freed from sulphur, although there is no real danger of contact with the silver solution. The apparatus is filled with silver nitrate solution, so that the top of the syphon is not quite reached and is then set upon the stand. The crucible rests in a well-fitting brass block to which the negative wire is attached. The anode consists of a silver cone suspended within the crucible by means of a silver wire attached to a horizontal bar insulated from the cast-iron base. When the electrolysis is complete, the residual nitrate of silver can be entirely removed without in any way disturbing the deposit by simply filling up the crucible with hot water several times. The crucible is then detached from the syphon, dried and weighed.

RULES AND FORMULÆ FOR INCANDESCENT LAMP WIRING.

BY

Clayton W. Pike.

IN THE ELECTRICAL ENGINEER of April 1, Mr. Carl Hering gives a diagram for the wiring of incandescent lamps so that all the lamps upon a pair of mains shall have an equal potential difference at their terminals.

If an arrangement, such as that shown in Fig. 1, were employed, the lamp *a* would have the same potentials at its terminals as any other lamp *b*, for the current for *a* passes over that portion of the mains whose length is $A^1 B^1$, while the current for *b* passes through the length B A, and since A B = $A^1 B^1$ and the current through *a* and *b* is the same in amount, the loss of potential on the mains for each would be the same, and therefore, the potential difference at the terminals of *a* and *b* equal. From this one might jump at the conclusion that any other lamp *c* would have the same potential. Commercially this conclusion is sufficiently true, and this was, without doubt, the sense in which Mr. Hering meant to use it. Indeed, until Mr. Loomis' criticism upon it in your issue of April 15, I have neither seen nor heard any dispute as to its being theoretically exact. Mr. Loomis points out that this is not the case and that the lamp *c* will have a less potential difference than *a* and *b*. It has seemed to me worth while to discuss the matter more in detail than he has done.

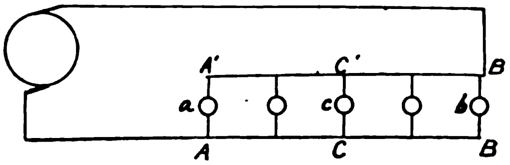


FIG. 1.

First, consider the arrangement shown in Fig. 2. Suppose the potential between A and B^1, which I will call $V_{A B^1}$ to be 100 volts, and that each lamp requires one ampere. Also that the resistance from A^1 to C^1 equals that from C^1 to B^1, A to C, or C to B, and each has the value 1 ohm. In the figure the number of amperes flowing through these parts of the mains are indicated. Now the drop in potential from B^1 to C^1 equals $2 \times 1 = 2$ volts. The drop from C^1 to $A^1 = 1 \times 1 = 1$ volt. Therefore the drop from B^1 to A^1 is 3 volts, and the potential difference between A and $A^1 = V_{A A^1} = 97$ volts. Similarly $V_{B B^1} = 100 - (2 + 1) = 97$ volts. That is, if we place a 97 volt lamp between A and A^1, and another at B B^1 they will burn with equal brilliancy. Let us now find the potential difference between C and C^1. The loss from B^1 to C^1 is $2 \times 1 = 2$ volts, and the loss from C to A $= 2$ volts. Therefore, the total drop is 4 volts and the potential difference $V_{C C^1} = 96$, which is one volt less than that at A A^1 or B B^1. For

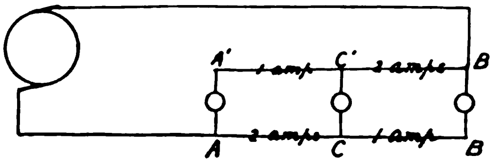

FIG. 2.

---

[1] See THE ELECTRICAL ENGINEER, April 8, 1891.

points intermediate between A and C we should get values of potential between 96 and 97 volts. This shows very clearly that the potential is not the same for all the lamps, and is least for the middle one.

Consider the matter from another point of view. Suppose that, as above, A and B^1 differ in potential by 100 volts. How shall we wire the three similar lamps so that they may have the same potential? Fig. 3 shows how this may be done. All portions of the mains are of the same guage of wire, and, since the same current flows in each, the drop of potential for equal lengths on A^1 B^1 and C^1 B^1 will be the same. This is also the case with the wires A C and A B.

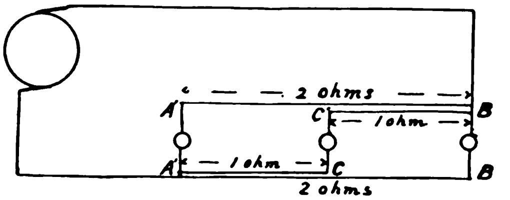

FIG. 8.

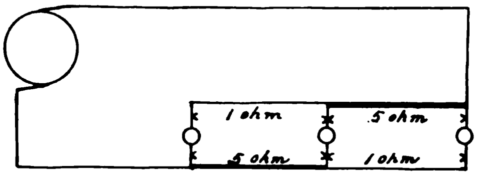

FIG. 4,

Therefore the wire B^1 C^1 may be laid alongside A^1 B^1 and in contact with it, and likwise A C put in contact with A B without in any way disturbing the flow of currents or the equality of potentials for the different lamps. The arrangement will then be as in Fig. 4.

We now see why the arrangement of Fig. 2 did not give the desired equality of potential. Computation similar to that given for Fig. 2 will show that the potential for all the lamps is the same, and has the value 98 volts, if V A B^1 is as before, 100 volts.

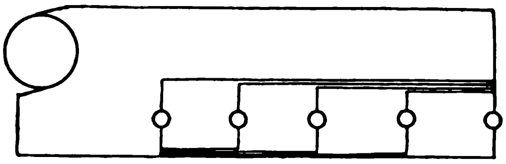

FIG. 5.

It will, of course, be noted that the resistance on the mains between the lamps is many times what would occur in practice, and that as this resistance diminishes, so does the variation in potential between the middle and end lamps. Practically the arrangement in Fig. 2 gives us equality of potentials among the lamps on that pair of mains. So far we must agree with Mr. Loomis, but when he says that "a little study will convince us that no system can be devised to produce the result (equality of potential among the lamps on a given pair of mains) in the sense of being theoretically perfect" I am inclined to think he has gone a little too far. Suppose we apply the principle of Figs. 3 and 6 to a considerable number of lamps giving the arrangement in Figs. 5 and 6. In Fig. 5 the wires are all of the same cross section and are calculated to give the desired loss when the current for one lamp is flowing through each. Suppose that each wire has a section of 1,000 circular mils. Fig. 6 shows the appearance when the separate wires have been pushed into electrical contact. The bundle of wires may then be replaced by solid wire which changes its area of cross section by 1,000 circular mils as it passes each lamp. Such an arrangement, though obviously impracticable, is yet, it seems to me, theoretically perfect in the attainment of the desired result.

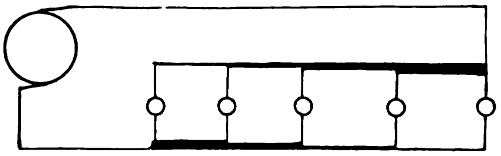

FIG. 6.

ELECTRICITY IN THE PRODUCTION OF ALUMINUM.[1]

BY ALEXANDER S. BROWN.

OF all the metals commercially familiar to us, aluminum has unquestionably made the most rapid progress. The long and tedious development of iron, steel, copper, tin, lead, zinc, etc., extending over centuries and centuries, is familiar to us all; the fact that this new metal (only discovered in 1827, and extracted in perceptible quantities not earlier than 1854) has already entered into commercial competition with the oldest and most useful metals, substantially at their own prices, would alone make aluminum a most interesting subject of study and speculation.

The author then traced the history of the metal beginning with the year 1760, or thereabouts, when a chemist named Morveau, by calcining alum obtained a substance which he called alumina. Shortly thereafter Lavoisier suggested the existence of metallic basis in the earths and alkalies, and, naturally, alumina was immediately suspected of being a metallic oxide.

As early as 1807, Davy and others tried ineffectually to decompose alumina by various means, including the use of the electric current. A chemist named Oerstedt thought he had produced the metal in 1824, but a German chemist named Wöhler was the first to actually demonstrate its existence. He extracted the metal in 1827 by decomposing the chloride of aluminum by means of metallic potassium; 20 years later he also reduced it with metallic sodium. The first commercial product was exhibited in 1854 by H. St. Claire Deville, a French chemist, whose researches as to its chemical and physical properties (fully reported in the French journals of the day), were so thoroughly exhaustive that his writings are still standard authority on the subject. He used several methods, the most successful of which was reduction by sodium. Up to 1886 the annual production of this metal was less than 10,000 lbs., of which 6,000 to 8,000 lbs. were produced in France. In 1860 it sold at over $90 per lb. In 1887 it was sold at $5 per lb. and is now selling at $1 for a commercially pure article—this term signifying about 95 per cent. purity in the metal. It is known that by processes now in operation, the metal can be produced in large quantities at a price which will put it on a par with copper, bulk for bulk.

As early as 1856, one Mons. Alfred Monier, of Camden, N. J., claimed to have successfuly made sodium by a continuous process, as a preliminary step in the manufacture of aluminum, and, later, he exhibited several small specimens at the Franklin Institute. This is undoubtedly the earliest record of the production of aluminum in this country. Three years later, in 1859, the first aluminum works in England were started at Battersea, near Londondon, but no details concerning them are obtainable. In 1860 other works were successfully established at Newcastle-on Tyne, by Bell Bros., which were operated with more or less success until 1874. Mr. James Webster, in 1882, re-established the aluminum industry in England, forming the Aluminum Crown Metal Company at Hollywood, near Birmingham. The principal features of his patent, which this company operated, were the large cheapening of the manufacture of alumina Al_2O_3. He claimed to obtain a product containing about eighty-four per cent. of alumina—a substantial gain upon other known processes—and also to save half the cost of manufacture by utilizing by-products.

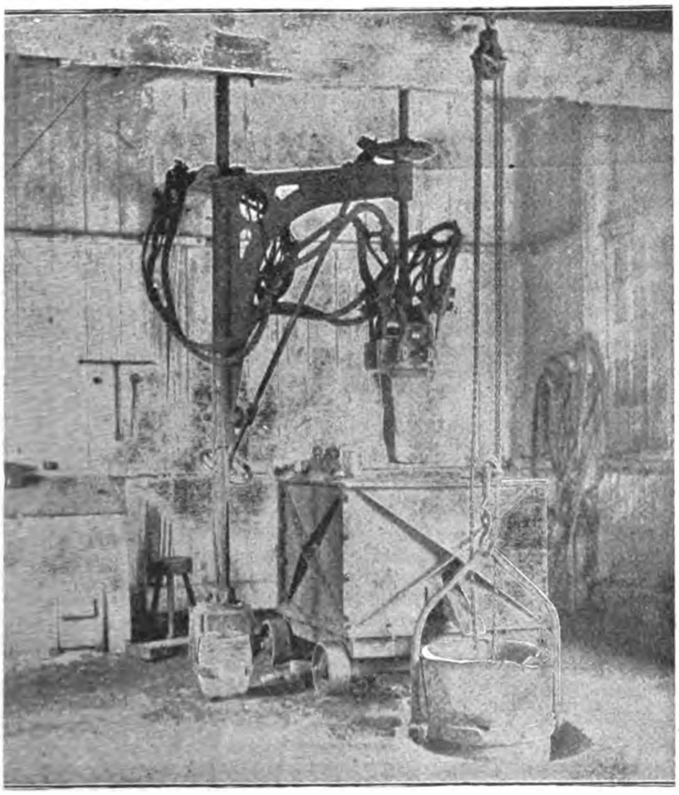
About 1886, a young Philadelphian—Mr. H. Y. Castner—invented and secured a number of patents to cover an improved and economical method of making sodium, which he claimed reduced its cost to twenty-five cents per pound. This invention he took abroad, and in 1887 the Aluminum Crown Metal Company, was re-organized under the name of the Aluminum Company,

---

[1] Abstract of a paper read before the American Institute of Electrical Engineers, April 21st, 1891.

Limited, and extensive works for the manufacture of sodium, primarily, and of aluminum, secondarily, were erected at Oldbury, near Birmingham. They were completed in July, 1888, and were alleged to have a very large capacity for producing aluminum. The reduction of aluminum at these works was conducted strictly on the lines of Deville's process—Castner's improvements being solely in the cheapening of sodium—and came to be known as the Deville-Castner process.

During the development of the various sodium processes to which I have above referred to, the possibility of utilizing electricity was not neglected. Among the earliest patentees in this field, were Camille A. Faure, in 1880–4, and R. Gratzel in 1883. Other inventors before those dates realized the value of electricity in smelting and other electro-chemical processes, but they were the first to give practical direction to theoretical speculation. Nothing has recently been heard of Faure's process, but that patented by Gratzel in Germany, in 1883, was practically utilized by a firm at Hemelingen, near Bremen, called the Aluminum and Magnesium Fabrik. The Gratzel process consisted, substantially, in electrolyzing a bath of fused chloride or fluoride of aluminum by means of anodes composed of a mixture of carbon and alumina, the current being furnished by a dynamo, but for some reason it was abandoned by the company, in 1887, for another process, the nature of which has been kept a profound secret.



A Heroult Crucible Used in Aluminum Extraction.

On April 2nd, 1889, Mr. Charles M. Hall, of Oberlin, Ohio, secured patents for a process of reducing pure aluminum. In this process alumina is dissolved in a fluid bath composed of aluminum fluoride and potassium fluoride, with, perhaps, an addition of lithium fluoride, this bath then being electrolyzed by means of an electric current conveyed to a carbon-lined furnace through an anode of some non-carbonaceous material. In electrolyzing this bath, the containing vessel is made to serve the purpose of the negative electrode. In another patent Mr. Hall claims the use of a bath composed of alumina dissolved in compound fluorides of aluminum with alkaline earthy metals, and in still another patent the use of a bath composed of alumina dissolved in the fluorides of aluminum, calcium and sodium, these materials being obtained by melting together aluminum fluoride, fluospar and kryolite. With this latter bath a carbon anode can be used without the bath being affected by its disintegration.

The Hall group of patents is now controlled by the Pittsburg Reduction Co., of Pittsburg, Pa., which has had its metal on the market since March, 1889. The plant has a capacity for producing about 300 pounds of metal daily, the selling price of which was $2.00 per pound, until the early part of March last, when it was reduced to $1.00 per pound for commercially pure aluminum of a guaranteed purity of 97 per cent. The reduction in price, considered in conjunction with the limited amount of pure metal produced would appear to confirm the generally received impression that while the pure metal is specially adapted to the manufacture of articles of art and ornament, it is not extensively displacing tin, platinum, silver, etc., to anything like the extent its admirers have supposed it would. The fact is, aluminum as a pure metal is not destined largely to supplant other metals in the arts and manufactures; it is to its alloys that we must look to redeem the inflated reputation of the pure metal. The true value and use of aluminum seems to have been forecast by Deville, who predicted for it an intermediate position between the precious and baser metals, in which relation to manufactures he said it was destined to fill a long-felt and important want. He doubtless referred to the pure metal, but, curiously enough, his prediction applies with greater force to its alloys, which have been demonstrated by actual use and thorough tests to possess physical and chemical properties that place them above all other alloys of copper, iron, and in some instances even of steel.

The electric smelting process of the Messrs. Cowles, of Cleveland, Ohio, was the first to secure a commercial footing in this country. The process may be described as the reduction of metals by smelting their ores with heat produced by the passage of an electric current through broken resistance material—that is, in the presence of an incandescent material, (carbon being generally preferred.) Stress is laid on the alleged fact that the reduction is purely and solely a smelting operation, due to a heat far greater than can be obtained by any agency other than the electric current. The electrical (chemical) effect of the current is distinctly disclaimed in their patents and publications. At each end of the furnaces are inserted rods of carbon. The charge consists, ordinarily, of a mixture (in different proportions) of an electrically resisting material—such as electric light carbon—and the ore to be reduced; though (in cases where the ore itself has sufficient electric resistance) the carbon is sometimes dispensed with. The current flows from the sides and ends of the electrodes through broken resistance material, which, of course, becomes incandescent. and the intense heat developed by this incandescence reduces the ore; the metal flowing to the bottom of the crucible and being subsequently dipped out when the charge is consumed. Neither aluminum nor any other metal is produced on a commercial scale by this process as pure metal.

The principal rival to the Cowles process for producing aluminum alloys is the Héroult process, which reduces aluminum and other metals from their refractory ores in the prescence of another alloying metal and is contradistinguished from the Cowles process mainly by the fact that it operates exclusively—or at least almost entirely—by utilizing the chemical or electrolyzing action of the current. This process is the invention of a young French electrical engineer named Paul L. T. Héroult, whose affiliations with the firm of Messrs. Henry Merle & Co., owning and operating the Deville Aluminum Works at Salindres, and his subsequent studies at the Polytechnic Schools at Paris and Switzerland, first directed his attention to the electrical reduction of aluminum. The success of a small Héroult plant put into operation at Boonton, N. J., for private demonstration purposes, in April, 1890, has been such as to give it rank among the prominent aluminum processes in this country. Having had exceptional facilities for studying the characteristics of this process during the past four months, I might be pardoned—especially as so little is publicly known of it—for describing it at length.

To give you a compehensive idea of the method employed by Mr. Héroult in manufacturing aluminum and its alloys, it will be best to describe the electrical plant and crucible separately.

The dynamo was designed by Mr. C. E. L. Brown of the Oerlikon works, Zurich, specially for electro-metallurgical work and is the only one of its kind in America. It weighs, complete over 19 tons and when driven at 220 revolutions generates a current of 35 volts and 35,000 amperes.

The machine is a 6 pole machine; having an armature of the Gramme ring type, and the current is taken off commutators at either end by 72 brushes. The armature is 39 inches in diameter and the shaft (including its clutch) is 11 feet 7 inches long. The commutators are each 19 inches in diameter and 20 inches long, each commutator containing 60 segments weighing 13 lbs. apiece, or a total of 780 lbs. for the segments for one commutator alone. The core of the armature consists of a very large number of sheet iron discs clamped together in a frame of aluminum bronze. About $\frac{3}{8}$ of an inch from the outside edge of the core, 120 holes pass from one end to the other, through each of which passes a copper wire ½ inch in diameter. These wires, which of course are thoroughly insulated from the core, form part of the winding. The remainder of the winding is composed of copper bars ¼ of an inch thick. 31 inches long and 2¼ inches wide.

At the time a friend visited the Schaffhausen (Switzerland) works last summer, where the Héroult process is worked by the Allgemeine Elektricitätsgesellshaft, of Berlin, who control the process in Europe, one of these 150 h. p. machines had been running without a moment's intermission 5 months, and another nearly

4 months. In actual work they are frequently run up to 300 revolutions, and though it sometimes happens in practical operations that heavy short circuits occur, there is hardly any perceptible sparking at the brushes, even when the current rises to 8,000 or more amperes.

At the Rhine Falls, at Froges, France, and at Boonton, these machines are coupled directly to turbine wheels arranged upon horizontal shafts. The frame to which the field magnets are attached is a solid casting, weighing alone over 9 tons. The field magnets are excited by a smaller dynamo driven by belting from a pulley on the main shaft. This exciting machine is run at 60 volts and 120 amperes.

At Boonton the bus wires are 8 in number; 4 positive and 4 negative; each wire being square and having a cross-section of one inch. The 4 positive wires pass directly to the clutch which holds the anode, and the 4 negative wires pass from the ammeter back to the dynamo.

The crucible (of which the accompanying engraving gives a good representation, together with the method now in use for raising and lowering the anode), is composed of a strong iron box which has a deep lining of carbon, previously ground very fine, mixed with sufficient tar and thoroughly compacted on the bottom and around the sides of the containing iron box. After the furnace is thus relined, the carbon is baked in order to drive away the tar and harden the lining. The carbon crucible itself actually forms part of the electric circuit. Héroult's is a continuous process; the reduced metal being tapped from the bottom of the crucible while the machine is merely stopped or slowed down for a few minutes. The interior dimensions of the crucible vary with the ore to be reduced, and the size and character of the anode used. Ordinarily it has an interior depth of about 22 inches and a clear space of 6 inches between the walls and exterior surface of the anode. The electric current passes into the crucible through the suspended carbon anode, the vertical position of which is controlled by an attendant who lowers it from time to time to preserve an approximately constant distance between the bottom of the anode and the surface of the molten bath in the crucible. In fact the anode usually dips several inches into this molten bath and in practice the intervening space between its bottom and the surface of the molten metal, is kept at about an inch by the attendant who, by watching the needle of the ammeter, is enabled to maintain the electrode in its proper relative position without difficulty. In order to get as perfect a contact as possible, between the furnace and the cables leading therefrom back to the dynamo, the cables are firmly clamped to a large block of zinc, which projects from the rear of the furnace and is kept cool by water circulating in pipes around which the zinc is cast. While, properly speaking, the crucible has no top, as a rule plates of carbon imbedded in dry alumina spread over the top of the crucible, are so adjusted as to fit close to the anode in order to retain most of the heat. The mouth of the crucible is formed of slabs of carbon built up funnel shape. The hearth or floor is pierced by a tap hole, which is kept closed by a plug of carbon or fire clay, and is opened from time to time to allow the molten metal to run into a carbon-lined ladle, from which it is cast into ingots.

There are a few distinctive but not important differences between Héroult's method of making alloys and reducing pure metals simply. In making alloys, the base alloying metal is first melted in the crucible by the current, or molten metal is poured into the furnace, to form a liquid metallic cathode. This is usually simply and economically accomplished by throwing pieces of the metal—copper for instance—into the furnace, seating the anode upon them and passing the current. At first the current is very unsteady, arcs constantly forming between the copper and the anode; but when the copper is entirely melted (and it takes but a very few minutes to melt 200 or 300 pounds) the ore to be reduced is added in sufficient quantities to form a bath, and floats on top of the molten copper. The anode having been raised so as to leave a space of about an inch between its bottom and the molten copper, the current becomes steady, and the operation is established. Thereafter the ore is introduced in small quantities, at frequent and regular intervals, until the desired percentages of aluminum or silicon contained in the alloy have been secured. This percentage can be regulated entirely at will up to about seventy per cent. of reduced metal. No external heat is used, and the process is absolutely continuous at the will of the operatives, which are special features of the Héroult system. The passage of the electric current through the bath, serves not only to keep the copper in a fluid state and to melt the ore, but also electrolyzes and decomposes the latter. It is a point of careful regulation in the Héroult processes to maintain only sufficient heat to keep the bath fluid, since any further expenditure is not only useless but lessens the output. The oxygen from the reduced metal combining with the carbon of which the anode is composed is burnt with the production of carbonic oxide gas, which escapes from the crucible around the sides of the anode and at the feed hole. The product is withdrawn at intervals by tapping the bottom of the crucible as in ordinary smelting. Each time the metal is tapped, a sample is carefully preserved for accurate analysis, to determine the percentage of contained aluminum.

From a metallurgical point of view, the amount of labor required to operate this process is astonishingly small. The metal produced in the Héroult furnace is sold generally in ingot form, just as it is tapped, without re-melting or being subject to any purifying manipulation. It is always, however, very pure, sometimes dropping as low as ninety-eight and one-half, but generally running over ninety-nine per cent. of absolute purity. This is largely due to the great care exercised in selecting raw materials. In making bronzes, the best Lake Superior copper is used, while the oxide from which the aluminum is reduced is an artificial product, manufactured in Prussia The number of materials from which aluminum may be reduced by these processes is very large, but the strong influence exerted upon this metal by impurities reduces those ores commercially available in this country to corundum and bauxite, both of which are largely used in making low grade metal for treating iron and steel. Kryolite—natural or artificial—is another mineral that plays an important part in the commercial production of pure aluminum, since it is the best flux for alumina, the ore from which the metal is generally reduced.

The very unusual qualities which give aluminum merit, and the great deprecation it undergoes when only slightly contaminated with foreign impurities, such as iron and silicon, together with the further fact that it has only been recently commercially produced of ninety-nine per cent. purity, have had a tendency to prejudice this metal in the eyes of practical people. From this depression it will slowly recover as they secure pure metal. In fact this very condition was foreseen by Deville, who very early pointed out that those handling aluminum and its alloys would be diappointed at the poor results they obtained where they used metal containing more than one per cent. of impurity.

Pure aluminum has a beautiful white color, slightly tinged with blue. It is somewhat fibrous in structure and bends considerably before breaking. If the metal contains more than one per cent. of impurity it becomes brittle and has a crystalline structure. When pure, it is soft enough to be easily cut with a knife, while the addition of a few per cent. of impurities makes it exceedingly hard. It melts at a slightly lower temperature than silver, and has a specific gravity of 2.6. Taking aluminum at 1.0 the following table (from Deville), will be of interest, as showing the compartive weight of the different metals:

Platinum	8.6
Gold	7.7
Lead	4.8
Mercury	4.2
Copper	3.6
Iron	2.9
Tin	2.8
Zinc	2.8
Aluminum	1.0

It has an elasticity similar to that of silver, and a tensile strength of about 26,800 pounds per square inch. The addition of 6 per cent. of copper, however, increases the tensile strength to that of wrought iron, and a slight percentage of silicon raises its strength to 90,000, though at the expense of other qualities.

The compounds of aluminum formed by the addition of copper, brass or iron, are unquestionably the most commercially important of the aluminum alloys. Aluminum combines with copper in all proportions, but its alloys are as easily influenced by impurities as is the pure metal. It is an important fact worth noting that, when alloys are made by mechanically mixing aluminum and copper, iron, etc., the product must be re-melted a number of times to secure any uniformity in the texture of the alloy. The finest alloys, by far, are those made by uniting the aluminum to the basic metal in atomic proportions, as it is reduced, as in the the Héroult process, the uniformity of whose alloys is remarkable. Probably the most useful compound of aluminum and copper is what is known as 10 per cent. bronze, containing 10 per cent. aluminum and 90 per cent. of copper. This alloy is an almost perfect imitation of gold in color, and is susceptible of taking and retaining a most beautiful polish. It can be rolled, or drawn, or cast very readily, but in casting, the bronze shrinks considerably, and care must be taken to have the feeders amply large. The tensile strength of this bronze is enormous, and the following table from "Trautwine Engineer's Pocket Book" shows it in comparison with other metals:

	Tensile Strength.
Cast brass	23,000
Annealed brass wire	49,000
Cast copper	24,000
Copper bolts	33,000
Annealed copper wire	32,000
Gun bronze of copper and tin (cast)	39,000
Cast-iron gun metal, U. S. Ordnance	30,000
Average American cast-iron	16,000
Good wrought-iron	50,000
Best American wrought iron, exceptional	76,000
Iron wires, rope	88,000
Malleable iron castings	48,000
Steel plates (rolled)	81,000
Cast steel, average Bessemer ingots	61,000
Aluminum bronze, in castings, over	100,000
Aluminum bronze "special" in castings up to	130,000

THE PROPAGATION OF HERTZIAN ELECTRICAL OSCILLATIONS IN AIR.[1]

BY MM. E. SARASIN AND L. DE LA RIVE.

We have already had the honor of presenting to the Academy the first results obtained by us on repeating the beautiful experiments of Hertz on rapid electrical oscillations. We confined ourselves on that occasion to the case of electrical oscillations transmitted along a conducting wire. Since then we have repeated another of Hertz's experiments, which consists in following the propagation of the electric induction across air in the absence of any metallic conductor. The primary exciter is placed in front of a large plane metallic sheet arranged parallel to it. The electric waves which emanate from it are propagated across the air, and impinge on the sheet of metal, which acts as a mirror, the reflected waves forming, with the direct waves, a stationary system, the first node of which is at the mirror itself. In order to study this system of wave outlines which is established in front of the mirror, a circular resonator is moved about in two different principal positions, (1) constantly parallel to the mirror and to the primary, *i. e.*, in the plane of the wave, (2) displaced into the plane drawn normally to the mirror through the axis of the primary, *i. e.*, in the plane of vibration. In both cases the results are absolutely concordant so far as concerns the equidistant positions of maximum and minimum E. M. F.'s. In addition to these two methods of proceeding, Hertz employed a third, which consisted in causing interference between waves arriving at the same resonator from the same exciter, either directly across the air or along a conducting wire. From these experiments he concluded, by the great wave length, that the rate of propagation across air in the absence of any conducting wire, was almost twice that observed along a wire, the two speeds being in the ratio of about 7.4. This disagrees with Maxwell's theory which makes the two speeds equal.

As reflecting surface we employed a large screen of sheet lead 2.8m. high and 8m. broad, kept plane and vertical by its own weight. The primary exciters and the large Ruhmkorff coils were the same that we employed in our previous investigations. The exciter was placed in front of the mirror, with its axis horizontal and its spark gap on the normal to the centre of the metal screen. Its distance from this was varied between 4m. and 10m. The circular resonator was fixed on a carriage sliding along a large wooden optical bench. We widely varied the conditions of the experiment, and repeated the observations a great number of times.

In these last investigations in air as in our previous ones with wires, we have, in fact, proved that *a circular resonator always gives the same wave length*, even when the dimensions of the primary exciter is varied within certain limits. We have, therefore, again observed what we have termed *multiple resonance*. In the case of large wave lengths (circles of 1 metre and .75 metre in diameter), which are very rapidly carried a long distance from the mirror and approach the direct action of the primary, one can only verify with any degree of precision one internode and node besides the node at the mirror itself. With smaller circles, for which the size of the mirror is more suitable, one can easily determine three internodes and nodes, including that at the mirror. The equidistance of the internodes and nodes is fairly satisfactory.

Our investigations show that the wave length obtained is in every instance sensibly equal in the case of propagation through air and along wires, the quarter of either wave length being nearly equal to twice the diameter of the corresponding circle. From this it follows that *the rate of propagation of Hertzian electrical oscillations, through air, is very sensibly the same as that of those transmitted along a conducting wire.*

College Notes.

UNIVERSITY OF KANSAS.

The Regents of the University have apportioned the appropriation for the ensuing fiscal year. The courses in civil engineering and electrical engineering have been removed from the College of Liberal Arts, and a School of Engineering has been established. Three thousand dollars have been appropriated for the further purchase of apparatus for electrical engineering. More than forty students are taking the electrical-engineering course at Lawrence this year.

The Thomson-Van Depoele Co. have shipped a 40 h. p. electric locomotive to the Rocky Mountain district and a 75 h. p. locomotive to the coal fields of Pennsylvania, both with full equipment for traction purposes. These machines will be used for underground haulage.

Literature.

Appleton's School Physics. By J. D. Quackenboss, A. M. Mayer, F. E. Nipher, S. W. Holman and F. B. Crocker. New York: *American Book Co.*, 1891. Cloth, 544 pp. 5x7¾. Illus. Price, $1.20.

This is in every way an admirable publication—the best of its kind for all pupils up to the age of 15, and, for that matter, a book which can be read with profit by many who are unfamiliar with modern ideas and discoveries in natural philosophy. A work that aims as this does to give the latest information in every branch, must necessarily be the production of more than one writer, and hence we find the different departments allotted with judgment to men who are specialists and experts in each case. A common error in the preparation of school books of this nature has been to entrust all the work to one hand, and the consequence has been that while upon a superficial examination, and to the uninformed, the whole might seem attractive and accurate, a scrutiny of any single section by those skilled in it revealed either numerous mistakes or statements of the "back number" type.

We have not looked very critically into the parts of the book beyond our own province, but judging them by the performance in the sections on electricity and magnetism, they must all be extremely well done, rendering the book about as near perfection as could be desired. The part on frictional and voltaic electricity has been handled by Prof. F. E. Nipher, and that on magnetism and the practical applications of electricity has been treated by Prof. F. B. Crocker. The young student cannot but feel as he goes over these chapters that he is in closest touch with a great science and an expanding industry, and that whether he would investigate or invent, electricity is to him another name for opportunity. The stages by which the work proceeds are also happily arranged, for after he has mastered the principles of sound, heat, light, etc., the young beginner comes to understand the relation to these phenomena of the steam engine, the dynamo, the battery, the electric light, the telegraph and the telephone. All is modern in treatment, all is fresh and down to date.

A word of praise is also due the illustrations, which are new and thoroughly helpful in elucidating the text. In typography, the arrangement is also to be commended.

Formulaire Pratique de l'Electricien, 1891. By E. Hospitalier. Paris, G. Masson, Price, $2.00.

M. Hospitalier's Electricians' Pocketbook has always found a welcome place on the work table of the electrical engineer and in this year's edition he has, if anything, made it more valuable than before. To this year's edition there has been added considerable matter that had been excised from former editions on account of lack of space, but in addition to this the part devoted to theory has been largely augmented by many valuable data on periodic currents. In the practical part considerable information has been added on specific resistance of metals, alloys and liquids, and the values of the principal magnetic constants of the steel employed in the manufacture of permanent magnets. Much new matter is also to be found on the distribution of currents and many practical figures on the construction of dynamos, transformers, etc. The work as a whole contains information which we have not seen embodied in any other one work intended for this purpose.

Steam: Its Generation and Use. New York, 1891. *The Babcock & Wilcox Co.* Illustrated, 152 pp.

This is the twenty-third edition of an admirable trade manual and catalogue. The first edition appeared in 1879, since which time the book has grown in bulk and value until it has now become a complete and most instructive treatise on a most important topic. The present issue, a handsome, freely illustrated, well-bound volume of 150 pages, contains not a little new matter of interest, including Mr. G. H. Babcock's pithy Cornell paper on the circulation of water in steam boilers; a table with formula on equation of pipes; and a revised table, due to Prof. C. H. Peabody, of the properties of saturated steam. During the past few years, Mr. Babcock, in a series of papers and lectures, has developed a complete theoretical and practical system of steam generation, and these are all given here in extenso, constituting a valuable body of data without which the literature of the subject would be sadly deficient.

We note in the statistical part, that the company's boilers, in connection with electric lighting work, have found their way all over the world, and that some of the stations run up to as much as 4,000 and 6,000 h. p. of boiler capacity. In the new work of electric railroading, the company has already a capacity, roughly totalled, of nearly 20,000 h. p.—a striking instance of the manner in which electrical engineering at each advance carries with it a larger promise and field for steam engineering.

---

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the monthly meeting of the Council of the Institute, the following gentlemen were admitted to associate membership:

Alexander, Henry, electrical contractor, 340 West 145th street, New York City.

Bedell, Frederick, graduate student, Cornell University, 118 Elm street, Montclair, N. J.

Bottome, Turner D., electrician and general manager, White House Mills, Hoosick, N. Y.

Bourne, Frank, electrical engineer, the Field Engineering Co., 15 Cortlandt street, New York City.

Burleigh, Chas. B., 620 Atlantic avenue, Boston, Mass.

Burton, Geo. D., president, Electrical Forging Co., 194 Washington street, Boston, Mass.

Casper, Louis, Wheatstone Repeater Chief, Western Union Telegraph Co., Cheyenne, Wyoming.

Clement, Lewis M., 1013 Central avenue, Oakland, Cal.

Cogswell, A. R., electrician and superintendent, Halifax Illuminating and Motor Co., Ltd., 34 Bishop street, Halifax, N. S.

Dunn, Gano S., student in electrical engineering, Columbia College, 66 West 93rd street, New York City.

Foote, Allen R., special agent, electrical industries, U. S. census, Washington, D. C. P. O. Box 432.

Foote, Thos. H., 104 Columbia Heights, Brooklyn, N. Y.

Hart, Francis R., superintendent of construction, Mass. Electrical Engineering Co., 4 P. O. Square, Boston, Mass.

Henry, John C., electrical engineer, 114 East 54th street, New York City.

Hering, Herman S., professor of applied electricity, Philadelphia Manual Training School, 553 North 16th street, Philadelphia, Pa.

Herrick, Charles H., manager and electrical engineer, Wright Electrical Engineering Co., 196 Summer street, Boston, Mass.

Holmes, Franklin S., electrical engineer with C. H. Davis, 120 Broadway, New York, 445a Macon street, Brooklyn, N. Y.

Johnston, A. Langstaff, civil and consulting engineer in the general construction of electric railways, 1105 East Main street, Richmond, Va.

Lovejoy, J. R., electrical engineer, Thomson-Houston Electric Co., 620 Atlantic avenue, Boston, Mass.

Schmidt, Giacomo, assistant general manager, Richmond Light, Heat and Power Co., New Brighton, N. Y.

Sheeby, Robert J., electrical engineer, Equitable Mfg. and Electric Co., 24 West street and 101 West 76th street, New York City.

Shepardson, George D., instructor in physics, Cornell University, Ithaca, N. Y.

Spaulding, Hollon C., secretary, Thomson-Van Depoele Electric Mining Co., 620 Atlantic avenue, Boston, Mass.

Tottingham, F. M., superintendent 2nd district, Edison Electric Illuminating Co., 49 West 26th street, New York City.

Thompson, Alexander, superintendent electrical department and chief engineer, Superior Water, Light and Power Co., West Superior, Wis.

Van Wyck, Philip V. R., Jr., 36 West 12th street, New York City.

Webster, Edwin S., Massachusetts Electric Engineering Co., 4 P. O. Square, Boston, Mass.

NEW YORK ELECTRICAL SOCIETY.

The next meeting of the Society will be held on April 30, at 8 p. m., at Columbia College, in Prof. Chandler's room, when Mr. Chas. Steinmetz will lecture on "The Elementary Principles of Designing Alternating Current Apparatus." The lecture will cover the whole ground in a popular and helpful manner, and should not be missed by anyone who is beginning to make a study of this important subject. Apparatus and current will be employed.

FRANKLIN EXPERIMENTAL CLUB.

The Thirtieth Regular Meeting of the Franklin Experimental Club of Newark, was held at the Club Laboratory, No. 6 Bloomfield Ave., April 21. Francis R. Upton read a paper entitled, "The Possibilities of Electricity." He described his early experiences in the electrical field when he first became associated with the developement of the incandescent lamp at Menlo Park. He declared that the growth of that industry in extent and efficiency, a growth with which his own business career was closely allied, made him feel prophetic in regard to the future. He stated that the incandescent electric light offered a most promising field for investigation.

Mr. Upton then took up the subject of heating and said that electricity was, theoretically, a perfect agent for the purpose: that it was even now possible to furnish electrically generated heat for domestic purposes and that it only remained to so reduce the cost of producing heat electrically as to place it on a commercial basis.

The speaker went into the subject of the generation and maintenance of power on a large scale, and which could be transported at will, and distributed in any desired amounts. Electricity, alone of all forces, has solved this problem.

The question of rapid transit was then taken up; also the advance being made in long distance telephony.

Mr. Upton brought his paper to a close with the prediction that New York would become the great electrical centre of the World, and that the city's growth and development would offer unprecedented opportunities for electrical expansion.

A general discussion followed and was participated in by Messrs. Wm. J. Hammer, Geo. B. Webb and Dr. T. W. Corwin.

Some novel incandescent lamp experiments were shown by F. W. Hillard and Paul H. Jaehnig.

At the next meeting of the Club, the first Tuesday in May, a paper will be read by Wm. J. Hammer, entitled "The Arc Light."

Legal Notes.

A "DOUBLE CARBON" INJUNCTION DENIED IN NEW ORLEANS.

In an elaborate opinion, Judges Pardee and Billings of the Federal courts, have denied the injunction sought to be obtained by the Southwestern Brush Electric Light and Power Company against the Louisiana Electric Light Company and the Brush Electric Light Company.

The suit was brought against the Louisiana Company for infringement of patent No. 219,208, which was granted to Chas. F. Brush, September 2, 1879, on "double carbon" arc lamps.

The court held that an injunction, as asked for, would temporarily, at least, until substitutes could be supplied, compel the Louisiana company to stop business, breaking its contract with the city, as well as private consumers, to the great injury and inconvenience of the public. Further than this, it appeared that even if the Louisiana Company could carry out its contracts by using single lamps, still the inconvenience and injury to the public would be great, because of the poor service while making the change, and thereafter while trimming the lamps in the middle of the night, and still greater because of the danger necessarily resulting to the agents engaged in the nightly duty of trimming the lamps while the conducting wires are heavily charged with electric currents.

The case presented was thus one where the benefit to the complainant was doubtful, and where the injury to the public and defendant were certain.

The court next cited numerous authorities bearing upon the rules governing the discretion of the court in granting or refusing injunctions in cases similar to this one.

The complainant company having introduced the double carbon lamps into public use, and the public having found them necessary to public safety as well as convenience for business purposes, a court of equity should not deprive the public of such use, at least on a preliminary hearing, and as the suit of a complainant who was in no condition to supply the public demand at any cost or expense, and who was destitute of pecuniary means and all apparatus to such a degree as to make it reasonably certain that an injunction causing such public inconvenience would be of no benefit to the parties obtaining it.

Affidavits of Messrs. Thos. L. Airey, Isidore Newman and others, capitalists and stockholders of the complainant company, show that the only remaining asset of the company is the patent, and that it is valuable if it can be protected.

In conclusion, the court says: "We are clear that the injunction *pendente lite* should be denied, and it is so ordered."

Messrs. J. R. Beckwith and H. L. Lazarus represented the complainants, and Messrs. R. S. Taylor and Farrar, Jones and Kruttschmitt the Louisiana Company.

ELECTRIC CUT-OFFS.

In the suit of David Rousseau *vs.* A. L. Bogart, the defendant has voluntarily consented to the entering of a decree, on April 20, in favor of plaintiff, the latter agreeing to waive all accounting and damages by the defendant and his customers in the past.

The suit involved the right to the manufacture of electric cut-offs having electro magnets and clock movements, under the following patents: D. Rousseau, June 5, 1883, 279,107; W. H. Sawyer, June 7, 279,073; Jacob Tirrell, Aug. 14, 283,303.

A similar suit is now pending in the U. S. Circuit Court for the Southern District of New York, against the Electric Gas Lighting Co., of Boston, which, it is stated, will be thoroughly defended, until a final decision by the court is reached.

Reports of Companies.

ABSORPTION OF THE BERGMANN MANUFACTURING CO.

The following notice to the trade has been issued by E. H. Johnson, president of the Interior Conduit and Insulation Co., and S. Bergmann, president of the Bergman Co : "The Interior Conduit and Insulation Company having acquired the entire property, patents and good will of the Bergmann Manufacturing Company, will henceforth prosecute as a branch of its regular business all that class of work heretofore done by the Bergmann Manufacturing Company. With the increased facilities and capital thus acquired, together with the continued association of the undersigned, you are assured that the well won reputation of the past for good and prompt work will not suffer in the future at the hands of the new company, which herein solicit a continuance of your favors."

ORGANIZATION OF THE THOMSON-HOUSTON FACTORY WORK.

Some important changes have recently been made in the manner of carrying on the work at the huge Thomson-Houston factories in Lynn. In order to be free to give more attention to the many important questions concerning the design of apparatus, and general questions of vital importance in the management of the works, and to avoid detail work as much as possible, Mr. E. W. Rice, Jr., the superintendent of the factory, has practically placed the management of the routine work there in charge of a manufacturing committee, as follows :

Mr. I. F. Baker, as "Mechanical Superintendent," in charge of all mechanical work, general discipline, construction, etc.

Mr. D. M. Barton, as "Production Manager," in charge of the entire output of the factory, which consists in balancing the production against orders and also keeping the factory supplied with raw material.

Mr. G. E. Emmons, as "Factory Auditor," in charge of the book-keeping, estimating, piece-work accounts and general labor accounts of the factory.

The positions occupied by these gentlemen are practically the same as they have been filling during the past three years, only with increased responsibilities, the three also acting as an executive committee, with full powers, to manage the factory in Prof. Thomson's absence.

The Mr. Barton mentioned above is a brother of Silas A. Barton, the former General Manager and Assistant Treasurer, now President of the Brush Electric Co.

Mr. Rice's position will be as hitherto, that of General Superintendent in general executive charge of manufacturing and technical work at the factory. It is also expected that he will have more time than in the past to visit the other factories of the Thomson-Houston Electric Co. and help to introduce as far as practicable any improved methods of management, manufacture or design of apparatus, found in the Thomson-Houston Electric Co. or its allied interests.

THE PUMPELLY STORAGE BATTERY CO.

Pursuant to a resolution of the Board of Directors, the assets of the Pumpelly Storage Battery & Electric Motor Co. will be sold at auction on April 30th, 1891, at 10 o'clock A. M., at the East front of the Springer Building, Nos. 205 & 207 South Canal St., Chicago Illinois, to the highest bidder for cash. The property to be sold consists of the patents, bills and accounts receivable, machinery and all other property and rights of the Company of every kind.

ELECTIONS.

Windsor Locks, Conn.—At the annual meeting of the Windsor Locks Electric Light Company, these directors were chosen : Charles E. Chaffee, Ezra B. Bailey, J. R. Montgomery, William Mather, J. H. Adams, Allen Pease, Samuel McAuley, E. D. Coogan and Henry C. Douglass. The directors chose these officers : President, Ezra B. Bailey ; vice-president. J. R. Montgomery ; treasurer and general manager, William Mather; secretary, Henry C. Douglass.

STOCKS AND BONDS.

San Jose, Cal.—The San Jose Light & Power Co. has voted to issue $60,000 worth of bonds to enlarge its works for gas, electric lights and power.

Talladega, Ala.—The Talladega Light Co. is considering the question of issuing bonds.

Burlington, Ia.—The Burlington Street Railway has become the Burlington Electric Railway Co., and announces an issue of 6 per cent. first mortgage bonds for the purpose of equipping the road with electricity.

Appointments, Etc.

Mr. H. F. **Parshall** has been placed in charge of the street car motor designing and construction, at the Edison General Works, Schenectady.

Mr. **Louis Walsh**, late of the Crosby Electric Co., has been appointed manager of the battery and carbon department of Alexander, Barney & Chapin, of this city, and has already entered upon his duties.

Mr. J. B. **Avery** is now in full charge of the Norwalk, Conn., Electric Light Co.'s plant, succeeding Mr. Bonnell as superintendent.

THE BERMUDA CABLE.

Mr. A. Livingston Bogart, electrical engineer, has just returned from Bermuda, greatly improved in health. He reports that Mr. Rippon, the manager of the Halifax-Bermuda cable, is busy on plans for the extension of the service. The enterprise so far has been a satisfactory one as an investment. The rates are high, being 81 cents per word, and the question of lowering the tariff is now under discussion. Some interesting telephonic tests over the cable were made by Mr. Bogart, and Mr. Ferguson, of the local telephone company, but they did not yield results.

A LONG STRAIGHT LINE OF ELECTRIC ROAD.

Mr. C. C. Upham, the manager of the Salt Lake Rapid Transit Co., writes us that they are now extending their line in Salt Lake City to the smelters. The distance on a straight line without a curve will be 7 miles, all on State street. While this is not by any means the longest line in one general direction, it is probably the longest piece of straight line in the country.

"BOY WANTED."

Mr. Samuel L. Powers, representing the New England Telegraph and Telephone Company, said recently that his company had the right to be recognized as a public servant, inasmuch as the messages which it carried would require the employment of ten thousand messenger boys. The free privileges which it accorded to cities and towns would require, on the part of the municipalities, an outlay for the plant of $300,000, and in addition it cost the company from $30,000 to $40,000 a year to maintain this gratuitous service.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of April 25, 1891, from New York, Boston and Washington.

NEW YORK.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED APRIL 21, 1891.

Accumulators :—

Method of Making Plates of Secondary Batteries, S. C. C. Currie, 450,884. Filed Nov. 18, 1890.

Comprises, essentially, a tube of woven material surrounding an interior conducting support, and between, upon, and into which is cast a porous crystallized metallic mass. Employs the fused salt or salts of a metal for the mass cast around the supports.

Alarms and Signals :—

Electric Bell-Pull, L. B. Tinkham, 450,706. Filed Oct. 11, 1890.

A device adapted to be applied to the shank of any ordinary bell-pull without altering or fitting the shank.

Thermostat, J. C. Sims, 450,896. Filed Nov. 29, 1890.

A thermostat of the class in which a thermometer or mercury tube having a series of contacts at different points is employed.

Conductors, Conduits and Insulators :—

Insulator, T. Creighton, 450,708. Filed June 19, 1890.

Intended for use in connection with telegraph wires, lightning rods, etc.; integral in all its parts; head has an angular groove and a direct transverse central pole to receive an ordinary lightning rod.

Electric Cable, W. I. Bunker, 450,784. Filed Oct. 7, 1890.

The conductor is composed of a series of particles (shown as spheres or rectangular blocks in the drawings) adapted to make contact with each other or to be separated from each other to break contact by bending or otherwise moving the cable.

Method of and Apparatus for Covering Electric Wires, J. E. Walcott. 450,830. Filed Sept. 30, 1884.

For covering insulated wires or cables with sheet metal; consists in bending a strip around a wire or cable and forming lips or raised edges upon the strip and then burning the edges together.

Dynamos and Motors :—

Electric Motor or Generator, J. F. Seiberling, 450,689. Filed Nov. 17, 1890.

Relates to the construction of the pole-pieces of the field-magnets in two parts, adjustable in relation to each other, and with faces adjustable at the sides of the armature; also includes details of the armature to facilitate removal and repair of its parts.

Self-Exciting Alternate-Current Electric Generator, W. Stanley, Jr., 450,641. Filed Oct. 19, 1888.

Designed to maintain a constant or an increasing or decreasing difference of potential upon the work-circuit throughout variations of load.

Claim 1 follows:

In a self-exciting alternate-current electric generator, the combination of two or more independent sets of armature coils, an electric converter wound with two independent coils, one connected in series with the field-magnet coils of the generator, the other in series with the work-circuit, each arranged to lessen the self-induction of the other, said converter being mounted upon the armature shaft and revolving therewith, and a rectifying commutator interposed in the field-magnet circuit.

Dynamo-Electric Machine or Motor, A. L. Parcelle, 450,975. Filed Oct. 14, 1890.

Relates to multipolar dynamos with ring armatures rotating about radial field-poles. Designed particularly for slow speed motors. Each field-pole acts simultaneously upon a number of armature coils.

Electric-Current Regulator, J. A. Williams, 450,985. Filed Nov. 15, 1890.

Consists in the employment of a compound thermostatic bar with the circuit wires of the dynamo and a pair of compound thermostatic bars oppositely arranged with respect to each other and connected with the movable brush holder; current shifting devices are arranged to throw the current into one or the other of the secondary compound thermostatic bars.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, C. Willms, 450,840. Filed Dec. 16, 1890.

Relates to the class of small portable batteries with sealed cells, and consists in details of construction of cell-cases for such batteries.

Lamps and Appurtenances :—

Socket for Incandescent Lamps, G. H. Alton, 450,605. Filed Oct. 22, 1890.

Details of construction.

Wall Socket for Incandescent Electric Lamps, P. Lange, 450,698. Filed June 11, 1890.

For supporting an incandescent lamp upon a wall and where it is not required to interrupt circuit connection at the lamp itself.

Ceiling Rosette for Incandescent Lamps, D. J. Cartwright. 450,991. Filed Nov. 10, 1890.

Details of construction.

Medical and Surgical :—

Clamp-Electrode for Electrical Dental Apparatus, T. S. Wilson, 450,690 Filed Oct. 22, 1890.

For securing the hold of an electrode in the hands of a patient during the act of treatment by electricity.

Miscellaneous :—

Safety Device for Overhead Electric Wires, M. Kerstein, 450,696. Filed Jan. 30, 1891.

For application to electric light wires; on the accidental breaking of a wire the broken end will be automatically insulated, rendering it harmless in case it falls upon another wire or upon any object or person.

Electric Valve Controller, C. B. Reardon, 450,872. Filed June 4, 1888.

Designed to enable a fireman holding the hose nozzle to control the flow of water through electro-magnetic devices.

Electrically Propelled and Steered Torpedo, W. S. Sims, 450,875. Filed Dec. 22, 1890.

The torpedo is directed from the shore through an electric cable; employs a steering magnet, and a generator on shore, a relay for directing current through the steering magnet, a resistance in a shunt around the relay contacts, and means for opening the shunt after the relay contacts are separated.

Electro-Magnetic Apparatus, L. G. Woolley, 450,923. Filed Aug. 16, 1890.

Included a battery, an electro-magnet, a primary and secondary coil, all so arranged that the primary current may be available for operating electrical apparatus such as annunciators, thermostats, etc., and the induced current may be available for medical purposes.

Automatic Electric Valve Controller, F. E. Chatard, 450,927. Filed Jan. 15, 1891.

Adapted for controlling the heating apparatus in buildings.

Electric Switch, J. A. Norton, 450,972. Filed Sept. 26, 1890.

Relates particularly to double-pole switches controlling both the flow and return wires of a circuit; is a spring acting switch and includes a novel form of terminals.

Railways and Appliances :—

Electric Railway, F. S. Culver, 450,613. Filed Sept. 25, 1890.

Relates to the traveling contacts; aims to provide a light and easy running two or four-wheel trolley, adapted to engage yieldingly both wires of a double circuit in which one wire is above the other; also includes an automatic switch and crossing.

Railroad Signaling Apparatus, J. D. Taylor, 450,645 Filed July 18, 1890.

An improvement on the invention patented to the same inventor Jan. 28, 1890, No. 420,235.

Electric Railway Block Signal, J. D. Taylor, 450,646. Filed Sept. 9, 1890.

Intended to give the control of trains on any system of blocks into the hands of one man, so that he may know the exact location of all trains.

Electric Locomotor, G. Westinghouse, Jr., 450,652. Filed Aug. 1, 1890.

Designed especially to secure the requisite friction between the car-wheel and track rails for carrying heavy loads and ascending grades. A main-truck receives the greater share of the weight; a pony truck may be placed near one end of the car, serving to steady its movements. The weight of the car is so distributed that the greatest pressure is normally upon that pair of main-truck wheels to which the driving power is directly applied; when the greatest power is required, for unusual load or for grades, the second pair of main-truck wheels is coupled with the first pair by interposed friction wheels, the pressure of which upon the truck wheels is determined by the torque exerted by the motor.

Trolley or Traveler for Electric Railways, S. H. Short, 450,683. Filed Apr. 9, 1890.

Relates to trolleys for making separate contact with two overhead conductors connected with opposite poles of the generators.

Railway Gate Crossing for Overhead Lines, E. Thomson, 450,687. Filed May 5, 1890.

Provides means for closing the line or giving the trolley a path when a car reaches the point of crossing.

Electrical Propulsion of Vehicles, E. H. Johnson, 450,742. Filed Aug. 8, 1890.

Adapted to regulate the power applied proportionally to the work required, and particularly to apply the power gradually at the time of starting the car: consists broadly in successively closing circuit from two or more electric motors mechanically connected to the wheels of a vehicle.

Insulated Electric Car, J. Stephenson, 450,846. Filed July 5, 1890.

Consists in means for insulating the car-body with its contents from all parts of the car that are in circuit or liable to be affected by the electric current.

Trolley-Wheel Support for Electric Cars, H. A. Webber, 450,853. Filed Aug. 18, 1890.

Adapted to permit a ready swing movement of the bearing in which the wheel is arranged without liability of cramping, and at the same time secure a perfect contact between the trolley-wheel and the conductor.

Electric-Motor Mechanism, S. E. Mower, 450,970. Filed Nov. 4, 1890.

Relates to means of transmitting power from an electro motor to the driving axle or axles of the car; employs a countershaft, gearing connecting the the armature and countershaft, a sprocket-wheel loose on the countershaft, a sprocket wheel on the axle and mechanism to render the sprocket-wheel fast on the countershaft.

Telegraphs :—

Means for Communicating Information, P. B. Delany, 450,615. Filed Nov. 26, 1888.

A visual signaling system by which news or matters of interest may be communicated to observers at a distance at night or in the dark. A transparency having letters of the alphabet and numerals upon its face is provided with electric lamps, one behind each letter or numeral, and which can be severally flashed from a transmitting station.

Printing Telegraph, S. R. Linville and L. F. Hettmansperger, 450,630. Filed June 23, 1890.

A system in which the instruments can be operated either as transmitters or receivers by alternating currents, transmitted through a single conductor from a source of electrical energy located either at a terminal station or at an intermediate station.

Printing Telegraph, S. R. Linville, 450,631. Filed Aug. 12, 1890.

An exchange telegraph system affording means of inter-communication between a number of subscribers connected to a central station.

Obituary.

PHILIP L. MOEN.

Philip L. Moen, President of the Washburn & Moen Manufacturing Company, died at his home in Worcester, Mass., on April 23. He returned home from a Southern trip a few days ago very much exhausted, and on Monday he suffered a stroke of apoplexy, with resulting paralysis. He did not rally from the shock. Mr. Moen was at the head of the biggest wire manufacturing establishment in the world. The company had big mills in Worcester, which employed 3,500 men, and had recently purchased a large tract of land at Chicago, where it is about to erect a large plant to make wire for the Western trade.

Mr. Moen was born at Wilna, N. Y., Nov. 13, 1824. He began business life as a clerk in a hardware store in this city, whose owners were the selling agents for the wire manufactured by Mr. Ichabod Washburn in this city. Young Moen married Mr. Washburn's daughter in 1846. Soon after he went to Worcester, and in 1850 was taken into partnership by his father-in-law under the style of I. Washburn & Moen, which continued the firm's name until 1868, when the present corporation was formed.

Upon the death of Mr. Washburn in 1870, Mr. Moen became President of the corporation, which position he since held. He was an exceptionally well-equipped business man, and under his management the corporation has prospered, especially since it purchased the barbed wire patents. He was always interested in educational and charitable enterprises, and gave liberally. He was a member of the Board of Trustees of the Worcester Polytechnic Institute. The company of which he was the head has been a very large manufacturer of wire for electrical purposes.

TRADE NOTES AND NOVELTIES

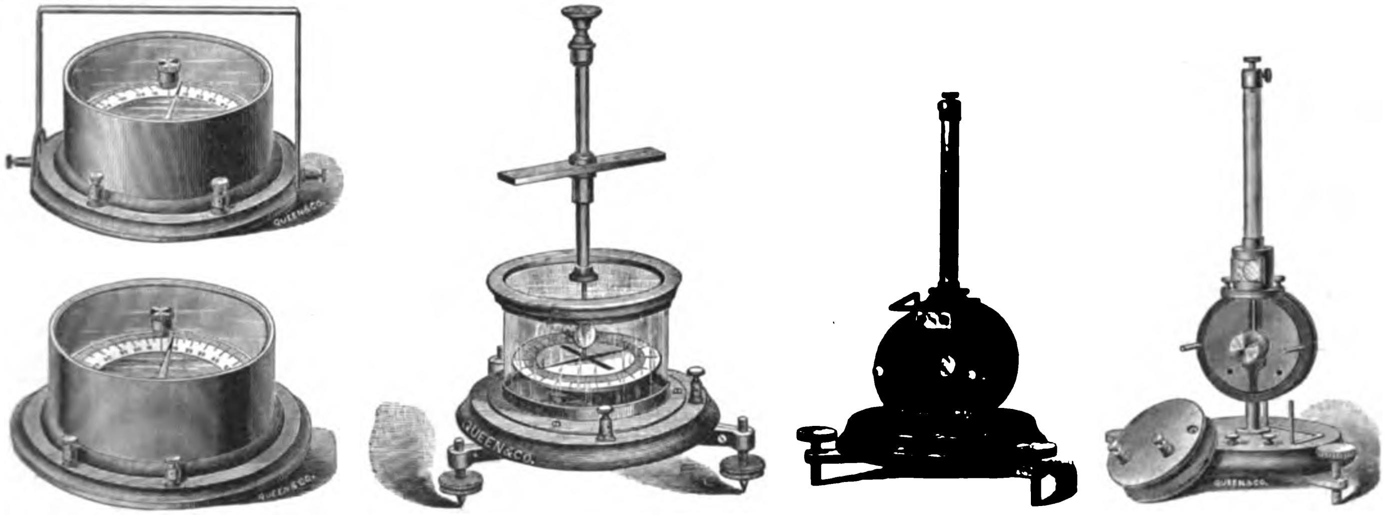
AND MECHANICAL DEPARTMENT.

A good advertisement is addressed to the eye, the mind, and the pocket, and captures all three at once.

ELECTRICAL MEASURING INSTRUMENTS FOR SCHOOLS.

Electrical science has made such rapid advances that untrained skill is no longer of much avail, nor have the colleges themselves been able to properly do all that is required of them in keeping at the head of investigation, while, at the same time, attempting to give elementary instruction. As a consequence each year sees more and more of this elementary work relegated to the high schools and preparatory institutions. Most of these schools, however, supported by municipalities or by private endowment, are unable to purchase the orthodox high grade testing instruments, even were it desirable to put such extremely delicate apparatus in the hands of beginners.

The accompanying illustrations show a number of electrical testing and measuring instruments, designed and put upon the market by Messrs. Queen & Co., of Philadelphia, expressly for the use of schools and students beginning laboratory work. These, while capable of doing very nice and accurate work, are especially adapted to the use of beginners, as they are strongly made and have their delicate parts so arranged as to be easily and quickly replaced in case of injury.



QUEEN&CO.
QUEEN&CO.
QUEEN&CO.
QUEEN&CO.

FIGS. 1, 2, 3, 4, 5.—ELECTRICAL MEASURING INSTRUMENTS FOR SCHOOLS.

In these instruments all unnecessary and superfluous finish has been avoided; at the same time, they are neat and well made and will not appear out of place in the best appointed laboratories.

The list, as published by Messrs. Queen & Co., is a most complete one, and includes all the instruments necessary for a thorough first year's course in laboratory electricity. Fig. 1, shows a neat form of horizontal galvanometer for ordinary work; this style is furnished with different windings, so as to measure, currents ranging from 0.01 to 40 or 50 amperes. Fig. 2, is the same thing with a heavy copper strip moving over a graduated arc, thus allowing the measurement of heavy currents and the demonstration of the laws of the cosine galvonometer. Fig. 3, is a fiber suspended galvanometer, pivoted on a vertical axis, for use as a sine galvanometer. Fig. 4, is a reflecting galvanometer of the Thomson type, in which a small brass cylinder with a glass face may be pushed backward and forward in the central axis of the coils, thus altering the size of the air chamber in which the mirror swings, and enabling the deflections to be made very dead beat. Fig. 5, is another "dead beat" galvanometer, of the Edelmann type; the mirror being attached to a bell magnet moving in a mass of copper. By removing this mass of copper the instrument is made ballistic, thus making it useful for measurements of condenser capacities, battery resistances, comparison of electromotive forces, etc. The coils are readily removable, as seen by the illustration, and may be changed in a moment for others of a higher or lower resistance. Both these last two styles of galvanometers are furnished wound to high or low resistances, as required.

A neat 16 page catalogue, I-70, of all this apparatus is issued by Queen & Co.

ADHESIVE BELT DRESSING.

It is of prime necessity to a central station man to keep his belts in good order, and the article manufactured as a belt dressing by E. F. Houghton & Co, of 211 So. Front St., Philadelphia, is intended to assist them in this respect. It is in use with much success by a large number of local companies all over the country. It is not a grease, but a bright oil, a little of which lightly applied by brush or sponge will have its effect in keeping the belt clean and in making it at once more flexible and durable. Owing to the increased grip on the pulley, given by its use, slipping is prevented, and higher economy is attained in the operation of the machinery and the steam plant.

HARRISBURG IDE AND IDEAL ENGINES.

A brisk and vigorous business is being done by W. R. Fleming & Co., 174 Fulton street, New York, in steam plants and power transmission machinery. During the past two weeks orders for some fifteen "Ide" and "Ideal" engines, together with other contract work, have been taken, inclusive of the following: One 500 h. p. Ide cross compound, New England Engineering Co., Waterbury, Conn.; one 75 h. p. Ideal, Pratt & Whitney Co., Hartford, Conn.; two 150 h. p. Ide tandem compounds, Somerville Elect. Lt. Co., Somerville, N. J.; one 150 h. p. Ide tandem compound, Hackensack, N. J.; one 25 h. p. Ideal, Tarrytown, N. Y.; two 100 h. p. steel boilers, with Weltmeyer patent furnaces, for Long Island City Elec. R. R.; four contracts for shafting and friction pulleys, manufactured by William Sellers & Co., and Moore & White Co., of Philadelphia, whose agents W. R. Fleming & Co. are. All of the above plants are equipped with the celebrated Jewell belting, which company they also represent. Several engines of well-known makes have been taken out in the above plants, and some bargains may be had to parties looking for second-hand machines.

CROCKER-WHEELER ELECTRIC MOTOR CO.

A visit to the headquarters of the Crocker-Wheeler Electric Motor Company, 430-432 West 14th street, New York, will show them at the mercy of carpenters and painters who are re-arranging and renovating their recently enlarged establishment. The alterations being made are now nearly completed, and promise an improvement in the appearance and convenience of the premises. Trade is good with this enterprising concern, and the outlook for the future is decidedly rosy.

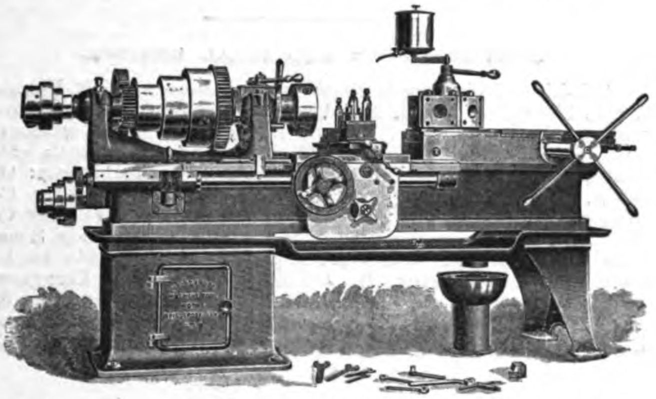
A FEW WORDS ABOUT GRAPHITE PAINT.

The life of an ordinary roof or outside paint runs all the way from two to five years, and it should be of personal interest to many to know of a paint that will resist acids or alkalies and withstand the wear and tear of the elements for 10 or 15 years. This seems to be a remarkable length of time, but the statement is vouched for by well-known people who have used Dixon's Graphite Paint made by the Jos. Dixon Crucible Co., of Jersey City, N. J.

They claim that Graphite Paint is not only durable but handsome and equally useful for all outside wood or metal work where a dark paint can be used.

A NEW SCREW MACHINE.

The accompanying illustration represents a machine manufactured by the Bridgeport Machine Tool Works, of Bridgeport, Conn., which contains some very desirable features. It is known as their screw machine, H. The bed is 7½ feet long, and the swing 20 inches over ways, and 11½ inches over carriage. The head is back geared and has a clutch for instantly changing from belt speed to back gear without stopping. It has a three-section cone for a 4-inch belt, the largest section being 14 inches in diameter. The spindle has a hole 2⅛ inches in diameter, and each end is fitted with a chuck for hexagonal, round, or square stock.



Screw Machine "H." of The Bridgeport Machine Tool Works.

In place of the usual cutting-off block, the lathe carriage has reversible cross and lateral feeds, and three tool posts. The turret is hexagonal in form and is 12 inches in diameter, with six 2½ inch holes. It has an automatic feed, and a device for unlocking and revolving at any point between 6 and 14 inches.

In addition to the regular screws, studs and bolts, this machine is very desirable where it is necessary to make a number of duplicate pieces, as special tools may be fitted, producing work at a great saving of expense.

The machine, complete, weighs 4,400 pounds.

SUCCESSFUL RUNNING OF EDCO STORAGE BATTERY CARS IN WASHINGTON, D. C.

The two Edco storage battery cars installed upon the Eckington and Soldiers Home Railway Co.'s track in Washington, D. C., March 13th, 1891, have, we are informed, given excellent satisfaction. On Sunday, April 19th, the two cars carried 1,293 registered passengers, besides nearly as many transfers, the cars running on the G. and Fifth street branch connecting with the main line of the Eckington road on New York avenue, where the trolley system is used. A fair calculation would therefore give 2,500 passengers as having been carried by the two Edco cars on that date, the greatest number registered on a single half trip being 75 passengers on the No. 1 car.

WOODHOUSE AND RAWSON, UNITED, LIMITED, ENLARGING THEIR WORKS.

In view of the large number of orders in hand for steam and electric launches, tugs, etc., together with others promised and in course of negotiation, Messrs. Woodhouse & Rawson, United, Limited, have resolved to extend their riverside premises, and have, therefore, purchased a piece of ground close to Kew railway bridge on the Surrey side, with a frontage on the river of between 600 and 700 feet, the total area being about 2½ acres.

The company will also have good dock accommodation in connection with the above, where tugs and barges can safely lie while undergoing any necessary repairs and alterations to machinery, propellers, shafting or inspection of bottoms. The new works are nearly opposite the two existing yards of the company, and will, it is expected, be in working order in the course of the next two months.

W. S. CHESLEY.

A number of recent sales are reported by Mr. W. S. Chesley, 171 Broadway, who makes a specialty of handling second hand plant and apparatus. They include two 750 light Westinghouse alternators and converters for 1,000 lights; a 10 light Weston arc machine with lamps; a 3 light American arc machine; a 50 light American; 1,200 light U. S. incandescent machine; a one h. p. motor and two ½ h. p. motors. Mr. Chesley has leased offices in the new Electrical Exchange building.

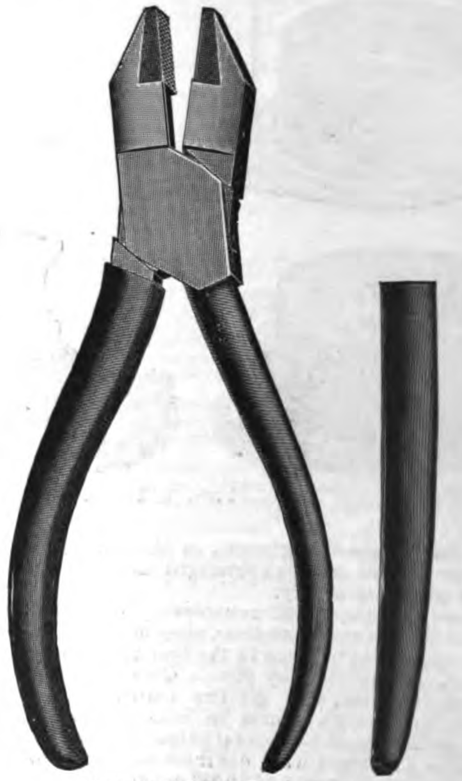
COLLECTING FARES ON THE LOUISVILLE ELECTRIC BELT LINE.

The Belt Electric Line Company has abandoned the use of bell punches on its cars. Receipts are given by the conductors for cash fares. These receipts are put up in pads, 100 to the pad. Each pad has its distinctive number and each receipt its serial number. The conductors are charged with their money receipts every night, and when they settle the next night must return the receipts in the pad, or must return cash to correspond with the missing receipts. In this way the transfer check is secured. The conductor is required to tear a receipt from the package in the presence of the passenger and is forbidden after that to allow a receipt again to come into his possession. In order that the public may be interested in receiving and taking care of these receipts, they are given a money value, that is, upon the return of 100 receipts at the office of the company the bearer will be entitled to six street car tickets. In other words, the receipts are worth 25 cents a hundred. This is certainly enough to justify people in saving them, and many small boys and girls will doubtless take an interest from this time on in collecting the receipts.

RUBBER PLIER HANDLES.

The men who work around live conductors know that the handles on their pliers ought to be insulated, and frequently resort to some crude method of supplying this protective covering. Thus they may slip a piece of soft rubber tubing over each handle or else they wrap tape around the same. Neither of these methods is satisfactory, but they show how great a need there is for some effective method of insulation.

The accompanying illustration shows a pair of ordinary pliers, protected by moulded rubber handles. These are moulded from good rubber stock, fit the handles snugly and give the hand an extra grip on the pliers. They are made to fit the various sizes of pliers used by electrical workers, and are already in use in many stations. George Cutter has the general western agency for them.



Rubber Plier Handles.

THE "A B C" FIBROUS DRY BATTERY.

Alexander, Barney & Chapin, 20 Cortlandt street, have just put on the market a new "Fibrous Dry Battery." It is reported to yield remarkable results, and Mr. Louis Walsh, of the concern's battery department, expects to do a large business with it. They have the sole selling agency for it.

Removal.—The offices of the Interior Conduit and Insulation Co., and of the Universal Arc Lamp Co. have been removed to the Edison Building, 42 and 44 Broad street, this city.

INTERIOR CONDUIT & INSULATION CO.'S TWIN CONDUCTOR.

THE Interior Conduit & Insulation Co. have issued a neat circular describing their "standard twin conductor," which we illustrate herewith. This conductor is designed to fill all the conditions of safety and reliability, particularly when employed in combination with their tubing. Beside its function as a safety conductor the following important advantages are claimed for it:

1st. It costs less money than two separately insulated wires of like quality and capacity.

2nd. It can be placed in smaller compass than any other double conductor or any two separately insulated wires, and therefore permits of the very desirable practice of placing the containing tubes on the ceiling and side wall surfaces, and then covering them with the ordinary plaster, thereby obviating the bad practice of running the tubes under the floors or behind the lath and plaster or of cutting channels in fire proofing.

TWIN CONDUCTOR.

3d. Its extreme flexibility renders it easy to draw in and out of tubing of very close approximation to its own diameter.

4th. The combination of the two conductors in one tube and in one strand, materially lessons not only the cost of material but of the labor in any given installation.

5th. It affords an absolute guarantee that any fault that may develop at any time will result in a short circuit, and therefore blow the safety fuse and thus remove all danger.

ARNY BELTING IN THE EDISON STATION AT PHILADELPHIA.

The immense plant of the Edison Electric Light Co., in Philadelphia, which, when completed, is to contain an aggregate of ten thousand horse-power, has adoped after a competitive trial of six months of actual service with four different makes of belting, the Peerless leather belt of C. W. Arny & Son, Philadelphia, as being best adapted for its severe service, and this firm now have a full dozen of their Peerless belts each 20″ wide, double, in daily operation. This service is particularly severe because the necessity of economizing space has led the company to use the narrowest belt possible to do its work, and because the pulling side of the belt is nearly a vertical line, the dynamo being situated directly over the engines and the tendency of the belt being to drop away from the bottom pulley with the slightest stretch. The construction of the Peerless belt reduces the matter of stretch to a minimum, so that there has been no trouble on that point, and though some of these belts have traveled nearly a mile a minute for from twelve to twenty-four hours per day for two years, there is no wear perceptible. Indicator tests show that a pair of these belts has transmitted as high as 462 h. p. without slipping, which in view of the very unfavorable conditions is remarkable, but attributable to the special transmitting surface peculiar to the Peerless belt.

FUNK & WAGNALL'S STANDARD DICTIONARY.

Mr. Robert Grimshaw, General Editor of the Trades Department of Funk & Wagnall's Standard Dictionary, being desirous of making as complete as possible his list of mechanical and industrial terms, requests manufacturers of machinery and tools having important parts not found on those of other makers, or the names of which are not yet in general use, to send the name, definition and use of each such part to him at 115 Bible House, New York City.

PARTRICK & CARTER CO.

John R. Galloway, electrical contractor, of Washington, D. C., has just closed a contract with the new Chamberlain Hotel at Old Point Comfort, for the installation of a complete system of guest call and fire alarm annunciators. The system to be used is that of Partrick & Carter Co., of Philadelphia, and will comprise a 600 number annunciator with return board and 600 combination bells.

"A POPULAR PUBLICATION."

THE ELECTRICAL ENGINEER, is undoubtedly a popular publication with the trade and persons interested in the development and progress of electrical inventions; its descriptions of new apparatus, and the illustrations of the same are very satisfactory.—*The Phonogram.*

CENTRAL STATION BLANKS.

IN reply to inquiries as to the forms and blanks for central station use, now being shown in Mr. H. A. Foster's copyrighted series of articles on "Central Station Management and Finance," we would state that arrangements for printing and selling these blanks have been made by the printer to THE ELECTRICAL ENGINEER, Mr. C. C. Shelley, 10 and 12 College place, this city. All orders for these blanks or inquiries as to price, should be addressed to him, and will receive prompt attention. The blanks, which are shown in reduced fac simile in the articles, are of good, ample size, and are well printed by him on good paper. Their cost is small and they will pay for themselves many times over in any station conducted with their help. Mr. Shelley has been the printer to THE ELECTRICAL ENGINEER for nearly ten years, and may be depended upon for prompt and satisfactory execution of any orders.

347 "THE ROOKERY."

The Western office of THE ELECTRICAL ENGINEER will henceforth be located in more commodious and sumptuous quarters at 347 "The Rookery," This step has become an imperative necessity owing to the growth of the paper and the numerous callers and electrical visitors to Chicago, who desire to drop in at THE ENGINEER'S headquarters in the West. The office will be found open at all times. Mr. W. Forman Collins will be delighted to see his friends and all the electrical fraternity there, and have them write as many full page articles for the advertising colums as they wish.

POLYCHROME FINISH ON TIN GOODS.

The Consolidated Fruit Jar Co., of 49 Warren street, this city, have long been known for the variety and excellence of their general sheet metal goods, and especially their products in the electrical line. They are now inviting attention to a novelty which they have worked out after considerable experiment. This novelty is in the shape of perfected lacquers, to produce a polychrome finish on ordinary tin goods. It will bear considerable ornamentation, and has a novel, pleasing appearance. The sample sent us suggests that many of our manufacturing readers putting up goods in tin packages might find it worth while to correspond with the company. Mr. A. L. Fisher is the secretary.

THE EDISON PLANT IN TORONTO.

A large number of leading citizens inspected recently the fine Edison Station in Toronto. Under the guidance of Messrs. Fred. Nicholls, manager; W. E. Davis, superintendent, and A. E. Anderson, assistant superintendent, the visitors were piloted through the premises and examined the many intricate and interesting features of the machinery. In the basement are eight Edison dynamos, six of 1,000 sixteen candle power lights and two of 2,000 lights, these latter being the largest in the Dominion. These supply seventeen miles of underground wires already in operation, and arrangements are completed for laying ten additional miles this summer. Two Armington & Sims high speed engines, one of 175 horse-power and one of 300 horse-power, and two Straight Line engines of 175 horse-power run the dynamos, each of these giving 260 revolutions per minute. In the boiler room are seven return tubular boilers of 125 h. p. each, built by the John Doty Engine Company of Toronto. The buildings are at present only partially completed, but when finished will be a handsome block of five stories and basement, in red brick with stone facings.

AT THE JAMAICA, W. I., EXHIBITION.

A very interesting exhibit of telegraphic apparatus has been made at the Jamaica exhibition, Kingston, Jamaica, West Indies, by Mr. H. C. Wilson, the efficient superintendent of Government Telegraphs. Mr. Wilson showed not only a variety of modern apparatus, but a number of relics. The electric lighting of the exhibition has also been quite extensive and successful.

ELECTRICAL SLATE.

Frederick Robinson, of Fair Haven, Vt., makes a specialty of supplying slate for electrical purposes, for the bases of switch boards and other apparatus. Mr. Robinson undertakes to supply slate that is free from iron or other conducting substances, and meets with such a demand from the electrical trade that he has been obliged to put up special machinery for the manufacture of bases in shapes and sizes, drilled, polished or marbleized, to keep up with his orders. Mr. Joseph Joutras is the selling agent for Mr. Robinson's electrical slate.

NEW YORK TRADE NOTES.

The Field Engineering Co. have removed to their new offices, 618, 619 and 620 Central Building, Liberty and West streets, where, with increased facilities, Mr. C. J. Field and his associates will handle their large and growing business.

Charles A. Schieren & Co., 45–51 Ferry street, this city, have been receiving numerous orders for perforated belting for electric street railways. Among them are the Brooklyn City R. R. Co., Brooklyn, N. Y.; Citizens' Electric Railway Co., Green Bay, Wis., and many others. Their perforated belting is found to be especially adapted to the uneven strain of street railway work. The different agencies of this firm at Chicago, Boston and Philadelphia, report business as booming in their different territories.

L. A. Fahr, who recently severed his connection with the United Electric Light and Power Co., has established himself at 415 Washington street, Hoboken, N. J., as electrical and mechanical engineer. He will deal in all kinds of electrical supplies and specialties, and also take 'contracts to construct private, isolated and municipal electric light stations for any system.

The Electric Construction & Supply Co. report, among the numerous sales for last week, 38 arc lamps of their regular type for the New York ferry house of the Central Railroad of New Jersey. The current for these lamps is to be supplied from the plant in this company's new building, corner Liberty and West streets, the cables to be run underground across West street. They also have contracted to install 185 of these lamps in the large store of The H. B. Claflin Co., this city. This makes the largest low tension arc installation up to this time.

The Crescent Insulated Wire Co., of Trenton, N. J., have nearly completed their factory. The machinery is now being placed in position and they will be manufacturing wire in about ten days.

WESTERN TRADE NOTES.

The Shultz Belting Co., of St. Louis, have just closed a contract with the St. Louis & Suburban R. R. Co. for two 72 inch belts each 154 feet long. Also ten belts 16 inches wide aggregating 700 feet. All belts to be double leather and cemented only, no rivets or pegs to be used.

Mr. Geo. T. Manson, of Okonite, spent a few days in Chicago last week, and called at the western office of The Electrical Engineer.

World's Fair Progress.—Work on the electrical departments of the Columbian Exposition is being vigorously pushed forward and every effort made to give the best facilites to the exhibitors of electrical machinery and apparatus. Already more than 100,000 square feet of space have been applied for and everything points to the fact that this will be largely increased within the near future. Prof. Barrett is handling the situation in a masterly manner and will put in a determined demand for everthing that the electrical people require to make an exhibit of unparalleled diversity and extent; and he will assuredly obtain every facility that he needs to this end. Something like 4,000 h. p. is at present called for partly in steam power for operating dynamos etc., and partly in the form of electrical energy for many different uses. This is, however, still a relatively insignificant figure.

Mr. E. W. Bennett, assistant manager of the Western Electric Co., left Chicago last week on an extended western trip to the coast in the interests of the company. The orders are already beginning to pour in and probably will continue to do so.

The Central Electric Company.—In future the important and varied announcements of the above company will be found displayed in generous Western full page style, in hues of black and orange, upon the inside page of the back cover of The Electrical Engineer, and week by week something new of absorbing interest to electrical people will be found there, telling of a place where they can obtain anything from a push button up to Okonite products by the car load, or "Packard" lamps by the ship load.

The Chicago Electrical Mfg. Co., are very busy on experimental and general electrical work. They are making quite a number of novel and valuable electrical specialties in the form of switches, rheostats, &c. They increased their manufacturing plant, recently, and now occupy the whole of the second floor at 73 W. Jackson street. Mr. J. D. Claghorne is the manager and Mr. C. P. Osborn, superintendent.

Mr. W. L. Adams, electrical engineer of the Northern Engineering Co., of Buffalo, N. Y., made a short stay in Chicago on his way to Marion, Ind., where he is building the new electrical railway plant of The Queen City Street Railway Co., there which comprises 6½ miles of road. Mr. Adams is the superintendent of this road.

Mr. Jas. A. Lounsbury, the electrician of the Thwing Electric Co., Lake and Peoria streets, Chicago, has recently built some highly efficient converters which have been felicitously named "The Porcupine," as they are a modified form of Mr. James Swinburne's "hedgehog" transformers. They are giving highly satisfactory results.

Mr. H. M. Underwood, the Western agent of the Interior Conduit and Insulation Co., recently made a short trip to Milwaukee, where his system received the usual hearty endorsement. Mr. Underwood reports the outlook for business in the Northwest as exceedingly encouraging.

Mr. Geo. A. Searing, the Western representative of the National Electrical Manufacturing Co., of New York, has just returned from a highly successful business trip to St. Louis.

Mr. Wm. Hood, the Western agent of the Accumulator Company and Electro Dynamic Cos., of Philadelphia, has largely increased his facilities at 239 La Salle street, where he now occupies the entire store. He will carry a large line of the above companies' goods and a complete outfit of adjuncts to their systems, as well as general supplies of high merit for lighting and power work. Mr. Hood, with his new facilities, will do a largely increased business.

The North American Electric Co., are selling a very large number of the "Gladiator" dry batteries which they manufacture. They will also place a new arc lamp for incandescent circuits on the market very shortly, together with a number of other good things electrical.

Mr. J. W. Hoffmann, electrician of Pullman, was a caller at this office last week. He is very busy wiring up cars for lighting and bells and making the various small parts used in this work.

Mr. H. F. Probert, M. E., for several years associated with the Sheffield Velocipede Car Company, of Three Rivers, Mich., manufacturers of railway specialties, has now connected himself with Fairbanks, Morse & Co., as their mechanical engineer.

Mr. C. A. Daigh, of the Electrical Engineering and Supply Co., of St. Paul, was a visitor to Chicago last week.

NEW ENGLAND TRADE NOTES.

The Russell Electric Co., of Boston, manufacturers of the new Russell disc carbon arc lamp, entertained a large party of ladies and gentlemen at their factory at Ballardvale, Mass., on Monday the 21st inst. The visitors about 70 in number were met at the Boston and Maine depot, by Mr. Albert W. Rounds, president, and Mr. Fred H. Carpenter, treasurer of the company, who conducted them to a special car in waiting. Mr. Edwin C. Russell, the inventor of the lamp, Mr. H. E. Chapman, vice-president of the company and manager of the factory, and Mr. Hector Denver, electrician, met the party at Ballardvale and assisted showing the visitors over the factory and explaining the merits of the lamp and the process of manufacture. The factory is now in complete running order and is well equipped to turn out large numbers of lamps weekly. At present there are about 500 lamps in process of construction, and the company have orders in hand for about 1,000 lamps. In the testing room there were displayed 25 lamps taking 9.6 amperes and about 46 volts, run by a 25-light Schuyler dynamo. The visitors expressed great satisfaction at the progress made by the company, and after a light lunch, returned to the city by the 1.25 express.

The Jewell Belting Co., of Hartford, Conn., are at present making a 36″ double belt for the Colorado Springs Electric Company, Colorado Springs, Col.; a 48″ double belt for the Omaha Electric Light Company, Omaha, Neb.; two 40″ double belts for the Johnston City Electric Light and Power Company, Johnston City, Tenn.; and a 40 inch double belt for the Connecticut Electric Company, Waterbury, Conn. The demand for a good belt for electric work is more active than ever, and the Jewell Belting Company, are gaining a wide reputation for using the very best material for dynamo belts.

Standard Electric Company of Vermont, have closed their office at 161 Franklin street, Boston, and will hereafter transact all their business from St. Johnsburg, Vt., where their factory is situated.

Mr. O. S. Platt, 88 to 102 Cannon street, Bridgeport, Conn., has issued a very neat and tasteful little pamphlet on his New England switch, illustrated and described some time ago in The Electrical Engineer. In sizes from 10 to 50 amperes, inclusive, it is mounted on porcelain bases, and from 75 to 100 amperes on slate bases.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XI. MAY 6, 1891. No. 157.

EXPERIMENTS ON THE RATIO OF ELECTROSTATIC TO ELECTROMAGNETIC INDUCTIVE DISTURBANCE BETWEEN NEIGHBORING TELEPHONE CIRCUITS.—I.

BY

A. E. Kennelly

THE following experiments were made with the object of not only verifying the experimental results obtained by Mr. J. J. Carty, as stated in his recent interesting paper on "Inductive Disturbances in Telephone Circuits"[1] read before the American Institute of Electrical Engineers, but also to check within fair quantitative limits the deductions from these results by reference to theory. It would seem that both these aims have been reasonably fulfilled.

Three hundred and five metres (1000 feet) of double conductor gutta-percha cable, shown full size in the diagram, Fig. 1, were laid out on the ground in a figure roughly representing a complete rectangle of sides 30 and 120 metres in length. The cable thus afforded two complete and independent circuits by the interior and exterior copper strands. The insulation between these was 20,000 megohms at the end of one minute, and their mutual electrostatic capacity 0.075 microfarad, from measurements taken at the time. The insulation of the outer strand to ground was about 4,000 megohms.

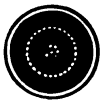


FIG. 1.

The following data give the dimensions of the cable employed :—

	Inner Strand.	
7 copper wires each	0.025″ = 0.064	cm. diam.
Strand diameter	0.102″ = 0.259	"
Diameter G. P. core	0.175″ = 0.445	"
	Outer Strand.	
18 copper wires each	0.036″ = 0.091	"
Strand diameter	0.247″ = 0.627	"
Diameter G. P. core	0.370″ = 0.940	"
Diameter over braiding	0.425″ = 1.08	"

Conductor resistance of inner strand 2.42 ω at temp. of test (12° C).
" " " outer " 0.5 ω " " "

The interior conductor was used as the primary or inducing circuit, and the exterior conductor as the secondary or recipient circuit.

The transmitter or source of disturbance was a continuous current dynamo giving 125 volts at its terminals (shunt wound), supplying about 50 amperes to incandescent lamps, and with one side grounded. A simple harmonic variation of electromotive force would, of course, be preferable for quantitative measurements, but there is some experimental difficulty in creating such a variation having the necessary frequency, while if the pure sine wave of disturbance is relinquished, and the exact shape of the wave is neglected, a dynamo becomes a very convenient transmitter. The small fluctuations in its E. M. F. produced by the successive reversal towards the external circuit of each armature coil as it passes under the brushes, are periodic variations whose frequency will be equal to the number of bars passing under each brush per second, and conversely it is only necessary to join a telephone across the mains of a continuous current circuit (through protecting resistance of say 10,000 ohms), to hear a note in the telephone whose frequency corresponds to the number of commutator bars passed over in one second by one brush. A trained musical ear will often identify this note, and thus the frequency, very closely, and the principle may be practically useful for distinguishing circuits operating at the same continuous pressure, but served by generators of different type, or to ascertain the speed of a dynamo armature when the number of its commutator bars is known. In this instance the telephone note was identified by the use of Helmholtz resonators as nearest to e''' of 1303 complete periods per second. By measuring the revolution speed of the armature, the number of bars passing under the brush per second was 1257. This number was therefore taken as the frequency of the periodic disturbance in these experiments.

Various combinations of the two cable circuits were tried so as to obtain electrostatic induction only, electromagnetic induction only, or both together. Of these the two most important cases bearing on the question are shown in the accompanying diagrams. Fig. 2, shows the arrangement of circuits in which electrostatic induction is almost wholly active, and Fig. 3, the case in which electrostatic induction is negligible, electromagnetic induction being displayed to full advantage.

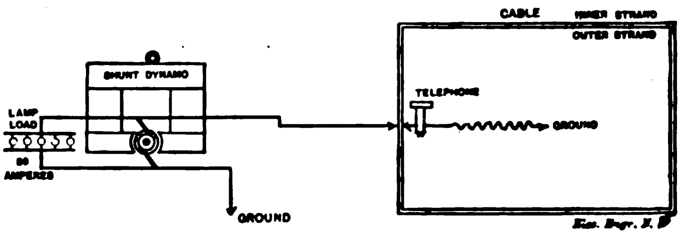

FIG. 2.

Referring to Fig. 2, the dynamo is connected directly to the interior conductor, while the exterior is connected to ground through a Bell telephone having a resistance of 73 ohms and an inductance of 113 *h*. The dynamo note was heard in this telephone. The effect was not due to leakage because a battery of fifty volts replacing the dynamo, and working through an interruptor, produced no sound. The disturbance was therefore accepted as wholly electrostatic. It required a very large resistance in circuit between the telephone and ground to bring the note down to the limit of audibility. With resistances of graphite, the amount needed to reach this limit was found to lie between 2 megohms and 10 megohms. It was estimated at 7 megohms.

In Fig. 3, the dynamo is shown connected through a galvanometer and bank of lamps to the interior conductor of the cable, the other end of which is grounded. The only appreciable inductance in this primary circuit is in the dynamo armature. Inductance is capable of being inserted between the galvanometer and lamps at will. The outside conductor completes its own circuit insulated from the ground through the telephone and resistance. Corresponding to different strengths of current in the primary circuit, resistance is added in the secondary circuit to bring the sound in the telephone down to the limit of audibility.

---

[1] THE ELECTRICAL ENGINEER, March 25, 1891.

The results are given in the following table.

1 Current in primary circuit (amperes).	2 Resistance in primary circuit (ohms).	3 Inductance added to primary circuit (millihenrys).	4 Impedance in primary circuit (ohms ω_1).	5 Resistance in secondary circuit (ohms).	6 Inductance in secondary c'r't (millih'rys).	7 Impedance in secondary c'r't (ohms ω_2).	8 $\omega_1\ \omega_2$
0.522	239.7	—	240	80,000	113	80,000	1.92×10^7
0.740	169	—	169	110,000	—	110,000	1.86×10^7
1.419	88	—	88	200,000	—	200,000	1.76×10^7
2.608	47 9	—	47.9	400,000	—	400,000	1.92×10^7
2.774	45.1	4.96	59.7	110,000	—	110,000	6.57×10^6
2.868	43.6	37.9	302.5	20,000	—	20.000	6.05×10^6
2.608	47.9	0	47.9	400,000	—	400.000	1.92×10^7

The first column gives the observed steady currents in the primary circuit, from which since the pressure was 125 volts, the resistances in the second column are found. The third column gives the inductance (in coreless coils of copper wire) added to the primary circuit, and from these with a frequency of 1257 periods, the impedance inserted in the primary circuit to the variations of its E. M. F. are given in column 4 In column 5, appears the resistance added to the secondary circuit in order to quench the dynamo note in the telephone, and since the only appreciable inductance in the secondary circuit was that of the telephone, negligible in series with the large resistances, the impedances of column 7 are only repetitions of those resistances.

The last column gives the product of the primary and secondary impedances. This value is nearly uniform except for the cases in which inductance is added to the primary circuit. The marked discrepancy in these two cases is perhaps due to the shunting action of the load circuit supplied by the dynamo, which, being nearly inductanceless, would reduce the periodic current in the primary circuit below the calculated amount, in about the ratio here represented. For the same reason the inductance of the dynamo armature (about 0.3 *h*) has not been taken into account.

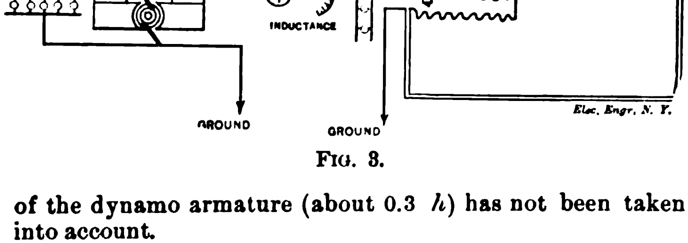

FIG. 3.

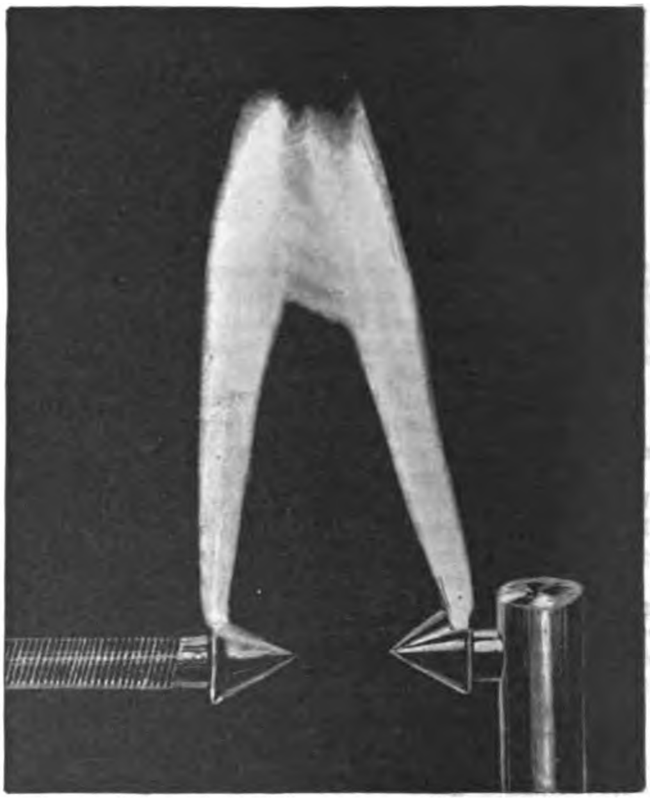
It appears however probable from an inspection of the results, that with a resistance of seven megohms in the secondary circuit, it would be necessary to reduce the primary circuit resistance to about 3 ohms in order to just render the dynamo note audible in the telephone.

The dynamo in these experiments was at a distance of about 250 feet from the telephone, and silence was obtained in every experiment as soon as the wires leading to the dynamo were disconnected from the primary circuit.

EXPERIMENTS WITH HIGH TENSION ALTERNATING CURRENTS.

MESSRS. SIEMENS & HALSKE, of Berlin, recently invited the members of the Elektrotechnische Verein of that city to their works to witness the demonstration of a series of experiments on alternating currents under a pressure of 20,000 volts. In order to show that the desired pressure was really *en evidence*, the high tension was conducted through a pair of wires of only 0·2 mm. diameter to a battery of 200 100-volt incandescent lamps, all connected up in series. An ordinary Siemens electric light cable was inserted, and broke down at a pressure of some 15,000 volts.



A 20,000 VOLT ALTERNATING ARC—(HALF SIZE).

At the end of the meeting a few experiments on the formation of the arc under this enormous pressure were shown. The sparking distance varied considerably according to the shape of the electrodes. At 20,000 volts a spark jumped from a ball to a ball about 10 millimetres, while between two points a sparking distance of 30 millimetres, and sometimes even more, was reached. This arc is shown half size in the accompanying engraving.

The arc which followed the jumping over of a spark made a loud humming and clapping noise, and flapped about, being easily carried away by the slightest draught. The arc could be drawn out horizontally to something like 100 millimetres distance between the electrodes, and even to a distance of 150 millimetres, when carbon pencils were used as electrodes, but it always remained standing up in a point.

A NOVEL GLASS POLISHING TABLE.

The Pittsburg Plate Glass Co., of Ford City, Penn., is adopting the use of electric motors in its large plant in that city. The company has a glass polishing table, which is said to be quite novel and economical in comparison with similar machines. These tables are over 30 feet in diameter and are revolved by gears which have heretofore been operated by steam. To run these tables a 100 h. p. motor is attached to a shaft which operates the gears. The Thomson-Houston Motor Co. has installed this first motor, which, though virtually on trial, is claimed to work very well.

ELECTRICAL STUDIES AT THE PRATT INSTITUTE, BROOKLYN.

BY

Alfred P. Boughton

N the 19th of May, 1887, a charter was granted whereby the organization of the Pratt Institute was completed. The Institute buildings cover an area of over 32,000 square feet, located in the block bounded on the north and south respectively by Willoughby avenue and DeKalb avenue, and extending through from Ryerson st. to Grand ave., Brooklyn, N.Y.

The work of the Institute deals mainly with special classes in the varied field of art, science, trade and technical instruction. Among these latter is a course in electrical construction.

The class in electricity begins with the first principles of magnetism, and in the laboratory the first work is with the torsion balance, with which the students experiment to show the law of inverse squares. The subject of magnetism is taken up very thoroughly. Bar magnets and iron filings are provided in the second laboratory experiment, and the students, of whom the writer has been one, are required to sketch in their note books the position taken by the filings, with the magnets in various positions. As will be seen in the engraving, Fig. 1, each pupil is provided with two cells of gravity battery beneath his desk; solenoids are made and soft iron bars provided for cores in order that the magnetic effects of the electro-magnet may be noted, and the students also learn of the magnetism caused by a current flowing in a straight wire. The next experiment has been that of the torsion balance with the electro-magnet, showing the effect on the instrument to be stronger than with the bar magnet, and also showing the varied result by decreasing or increasing the number of turns of wire on the magnet, which experiment was afterwards tried with the dynamo current, incandescent lamps being wired in series and series multiple with the solenoid, the number of turns thereon being varied, dynamo current from the plant in the basement of the building, being on tap at each student's desk.

Then, in the lecture room, the formula $C = \frac{E}{R}$ being explained, the laboratory work consisted in finding that $E = CR$. This was done by each student being furnished with a galvanometer, with calibration attached, and a resistance box, measuring the E. M. F. of the batteries, the internal resistance of which was estimated; and later, using dynamo current, the resistances of incandescent lamps were shown, the E. M. F. and current being indicated by the proper instruments.

Other ways of finding resistance—by substitution and by decreasing the current—were also shown last season and worked out by the class, the finding of the internal resistance of the batteries being one of the experiments. The Wheatstone bridge was also taken up in this connection, and the principles thereof very fully explained by the instructor, several experiments being conducted in the laboratory. The fact of the resistance of wire varying inversely as the square of the diameter was treated of in the lecture room, and in the laboratory work was done in this direction to demonstrate the fact. Under the head of resistance, I might mention that the class one evening tested the resistance of several of its members, the average of the thirteen who were willing to try the experiment being 3,518.31 ohms.

Instruction was given in the lecture room concerning induction coils, and experiments were made in the laboratory with them. An evening was spent on the subject of electroplating, and the students were furnished with a copper strip, and various substances, a carbon pencil, lead, tin, etc., to be plated. This was a very successful experiment, and one of the most interesting.

The electrical class in the Pratt Institute meets twice each week for two hours, one of lecture, and the other experiment. While the above laboratory work has been going on, the instructor has lectured on primary batteries,

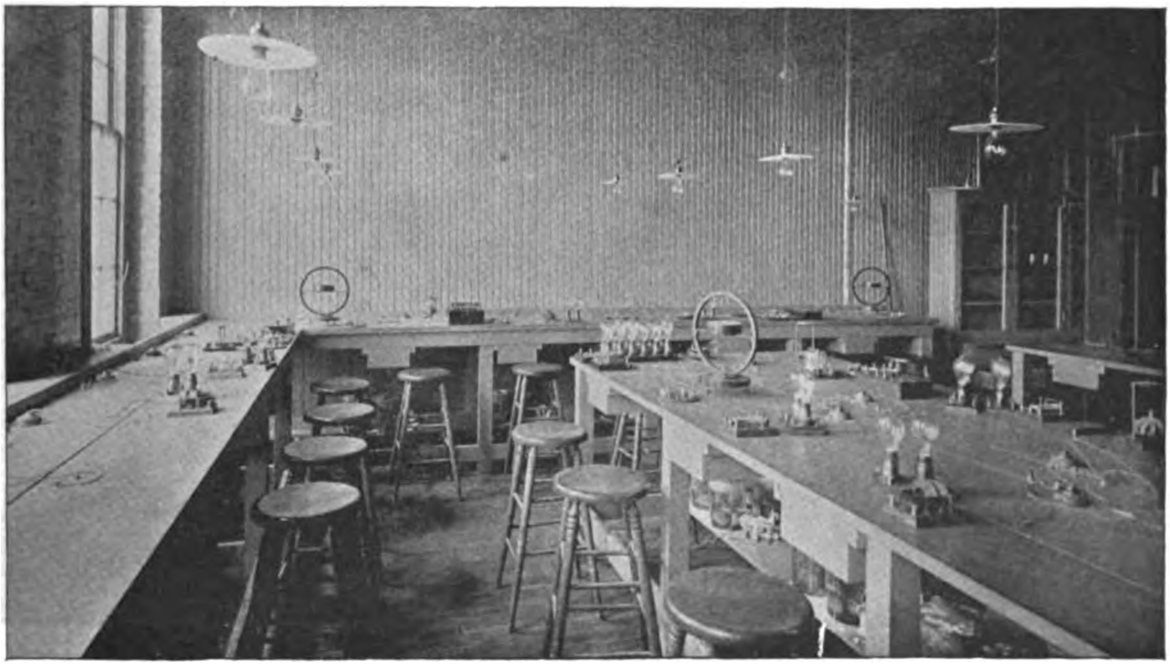


FIG. 1.—ELECTRICAL LABORATORY, PRATT INSTITUTE, BROOKLYN.

(and in this connection has given the class the E. M. F.'s of the best known makes of cells), storage batteries, telephony, telegraphy, electroplating and welding. Various laws have also been explained, a multitude of formulæ worked out, and a number of interesting tables furnished.

As will be seen by Fig. 2, there are in the laboratory a 5 h. p. Thomson-Houston motor, driven by the dynamo in the basement, an Edison incandescent dynamo capable of lighting five 110-volt lamps, and a 50-volt Westinghouse alternator, each of the latter being driven by the motor. The students are instructed as to the manner of calculating the commercial and electrical efficiencies, are shown the characteristics of the different forms of machines, and experiments are conducted to give the pupils opportunity for plotting the curves themselves, as also the curves showing variation of watts and stray power with fluctuations of speed, as well as the plotting of the curve of saturation of field magnets.

In the lecture room both arc and incandescent lighting, the two and three wire systems, were discussed, and arc lights were placed in the laboratory for the use of the class. The subjects of power transmission and street railway work were also treated of. The course was confined strictly to lectures and laboratory work, there being no text books at all, the only outside work being the necessary writing up of the students' note books for examination by the instructor.

The principle of individual laboratory work is insisted upon and the size of classes strictly limited to the capacity of the laboratory.

As will be seen, the course first treats of the scientific data of electricity and magnetism, and then traces the applications of these to the methods and constructions of actual practice.

The lecture and laboratory rooms are situated in the Mechanic Arts Building, under the supervision of Mr. C. R. Richards, while the students were under the immediate care of Mr. F. W. Dunbar, electrical engineer.

MR. BLANCHARD has resigned from the position of manager of the Norwalk, Conn., Electric Light Co.

ELECTRO-CHEMICAL EFFECTS ON MAGNETIZING IRON.

In a Paper recently read before the Royal Society, Mr. Thomas Andrews, F. R. S., gave the results of some experiments carried out by him on the effect of magnetization on the relative electro-chemical position of a pair of bright iron bars, one magnetized by a coil, the other unmagnetized, when simultaneously exposed to the action of various powerful oxidizing agents and saline solutions. He employed long polished rods of soft wrought scrap iron 0.261-in. in diameter. Each pair of pieces was adjacently cut from the same iron rod, so that they might, as near as practicable, be of identical chemical composition and molecular constitution. The pieces were placed in the legs of a U tube containing the electrolyte, every care being taken to check any E. M. F. which might occur owing to the rise of temperature in one leg caused by the current in the magnetizing coil. The solutions employed were potassium chlorate + one-fifth and one-third nitric acid, potassium chlorate and hydrochloric acid, 25 per cent. and 20 per cent. aqueous solution of nitric acid, a 50 per cent. aqueous solution of hydrochloric acid, concentrated sulphuric acid (Sp. gr. 1.84). The magneto-chemical effects were very small, being usually of the order of 1×10^{-3} volt. The magnetized rod was in every instance, except when dilute hydrochloric and concentrated sulphuric acid were employed, the positive element. In the exceptional instances alluded to, the electro-negative effect occurs, possibly owing to the presence in the solution of such reducing agents as nascent hydrogen.

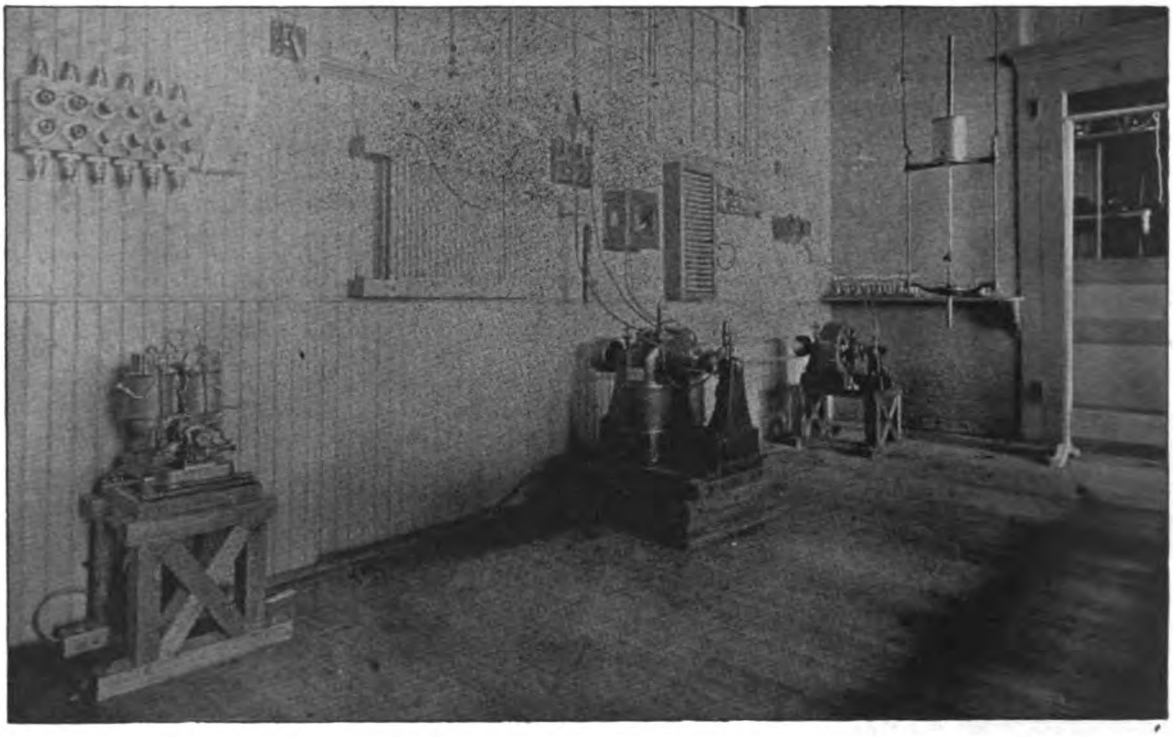

FIG. 2.—ELECTRICAL LABORATORY, PRATT INSTITUTE, BROOKLYN.

PROF. THOMSON'S WATCH CHAIN.

Prof. Elihu Thomson wears a unique watch chain, the links of which are welded by electricity. In part of the chain, links of gold and platinum alternate. Other links are made of sections of these metals.

MR. HENRY GRAY has been promoted to the position of assistant superintendent of the Edison Electric Light Co., of Paterson, N. J.

CENTRAL STATION MANAGEMENT AND FINANCE.—III.

BY

Horatio A. Foster

Electrical Department.

The reports and records for this department are necessarily more in number and worked out in greater detail than those of other departments. The blanks required are as follows:

No.	3.	Report of Circuit Tests.'
"	4.	Inspector's Report.
"	4A.	Complaint Card.
"	6.	Dynamo Engineer's Report.
"	6A.	" " " (small).
"	7.	'Daily Lamp Record.
"	7A.	Arc Switchboard.
"	8.	Ampere Report.

Jointly with the Supt. of Construction the Circuit Register blank, No. 3, is used.

Blank No. 3.—Report of Circuit Tests.

The dynamo engineer is the executive officer of the dynamo and lamp departments and under the supervision of the electrician, who, by the way, is usually the superintendent. The dynamo engineer has charge of the switchboards, dynamos, lamps, and in fact all electrical machinery and repairs on the same.

He must see that the circuits are in proper condition to run as tested from the switchboard, and by this we mean chiefly the arc circuits, as incandescent and some power circuits are run all the time, and can have only such tests as are made by ground lamps and detectors, of which there are many very good ones to be had.

Arc circuits, when not in use, are tested three or more times per day for continuity and grounds, and if found in any way defective, are immediately reported to the superintendent, who sends some one to hunt up the faults. At present such testing is done with the ordinary magneto-bell, but the galvanometer is coming more into use, as the managers become acquainted with it. Soon we hope to make and use blanks which shall record the insulation of all lines. After starting, the circuits should be tested every hour with ground wire through high resistance, say a bank of incandescent lamps. Mr. M. D. Law, formerly of Philadelphia, made a very ingenious use of the lamp-bank. His lamps, for full c. p., required about 50 volts. He placed a number in series with a voltmeter across the terminals of one of them, to indicate when full potential or c. p. was reached. Then by turning off lamps until a number showed full potential, he could tell by that number about where his ground was located on that particular circuit.

Blank No. 4.—Inspector's Report.

As in all well-regulated stations, there is generally serious trouble on only a few circuits, it is thought unnecessary to make mention of circuits other than those which have faults. Therefore we think form No. 3 herewith covers the ground.

The condition of the weather cannot be stated at too many parts of the day, hence the number of reports having a line for that condition.

Inspector's report, form No. 4, is used by night circuit inspectors, and in fact by any one who has a statement to make in regard to the condition of circuits or apparatus. For instance, trimmers report lamps out of condition, globes broken or other faults. Inspectors report lamps out, with the cause and the time out. This is recorded the next day on the lighting register, and if confirmed by the trimmer's report or book, is deducted as rebate from the customer's bill. Incandescent or motor inspector's report refers to switches, fuses, cut-outs, lamps renewed, etc.

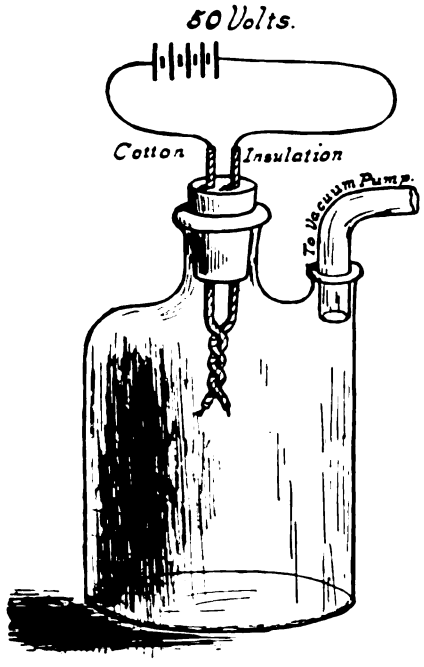
OIL AS AN INSULATOR FOR HIGH POTENTIALS.—II.

BY

David Brooks

The accompanying diagram represents a semi-exhausted chamber into which two cotton-covered wires are introduced, and between which a disruptive discharge is produced with a current of fifty volts; and, after once started, this arc is maintained with a current of two volts or two Daniell cells. The illustration is nothing more than what is shown by a Geissler tube.

Now, in the insulation of conductors that are coiled and uncoiled, air spaces are liable to be formed. The insulation is thereby rendered non-homogeneous, and currents of high potential are liable to break through and produce what is sometimes called disruption. This feature in underground subways is the source of much expense and annoyance. If you go into the yards of the different electric light companies in the city of New York, you will find tons of cable that have been disrupted and rendered useless from this one cause.



Experiment With Disruptive Discharge in Semi-Vacuum.

It is also the cause of the many explosions that have occurred in the subways of New York, and to prevent these explosions there is now employed a large force opening the manholes and ventilating the subways by the use of rotary fans, and other means. In New York, if the ducts are tolerably clear of gas, no explosion occurs where the conductors are encased in lead pipe. The conductors are drawn out after becoming useless and put away among the scraps of the yard, or sent to the factory again where they are stripped of the lead and re-covered.

In Philadelphia the subways are made of wood, and disruption not only produces explosions, but often sets fire to the wood of the subway. It is not two weeks since a fire of that nature occurred between Seventh and Eighth streets in Chestnut street, and a gang of men were employed for eight days putting in a new subway and replacing the burnt portions of the cable. These wooden subways are used to a considerable extent by the Edison Company, not from choice but from necessity, and the superintendent states that they have a break-down or a fire as often as once per day.

In the foregoing article I explained how much easier it is to spark through natural air and a semi-vacuum than through oil. Wires, covered with cotton one-sixteenth of an inch and, say, one-eighth of an inch apart in oil, will withstand an electromotive force that sparks four inches through the air. Roughly, it takes thirty-two times the potential to spark through oil that it does through air; hence, the great advantage of having a conveter immersed in oil as compared to one not in that condition, or used in the ordinary manner.

Very many converters are injured by lightning; but electric light conductors are not nearly so much exposed to atmospheric influences as telegraph conductors; yet they are much more liable to injury, from the fact that an atmospheric impulse may produce a spark that would not injure a relay, being no more than is often used upon an electric gas-lighting burner; but this miniature spark when once produced, is followed by a current of thousands of times more amperage, that produces the mischief.

All these objections to the use of subways or ducts are avoided by the use of oil, and when it comes to converters used in connection with overhead conductors, the chances of interruption by atmospheric discharges are immensely reduced.

It is often said that in the subway system you can pull out the conductors, and draw in others. With the oil system, up to this date, there has never been an occasion to require the conductors to be drawn out. But if there were occasion, a thousand feet could be drawn out easier than two hundred and fifty feet in any subway system.

Bearing in mind that an electric light conductor, of whatever size one may choose, costs from four to six times as much when drawn into a subway as when insulated with oil, and all other conductors in the same proportion, and remembering also the cost of the subway as compared with the single oil pipe, then the cost of the oil system as compared with the subway system, is less than the proportion of one to ten.

THE SING SING EXECUTION PLANT.

Warden Brush, of the State Prison, who retires from his position on May 1st, will leave behind him an execution plant that he believes to be perfect in its way. He has built a small wing to the building in which capital prisoners are confined, as an execution chamber. This wing is divided into two rooms. In the first is the death chair, which is of heavy oak, and in which the culprit can be securely strapped in less than one minute. Back of the chair is a small closet, built out from the partition. On one side of this is the switchboard, with the voltmeter, resistance box, &c. Over this are 20 incandescent lights in series, calling for 2000 volts when run at full power.

The warden, standing at the chair, can give the signal to the man at the switchboard. The pressure of the button signaling the dynamo room will bring the full current to the incandescent lights. None goes to the chair until the warden gives another signal, when the operator in the closet, who cannot be seen by anybody present, switches the full current from the lamps to the wires leading to the chair. The dynamo is now 1,000 feet away from the execution chamber; but it is intended to bring it up to the room adjoining that in which the chair stands, so that the whole apparatus will be in charge of men within reach of the warden's voice.

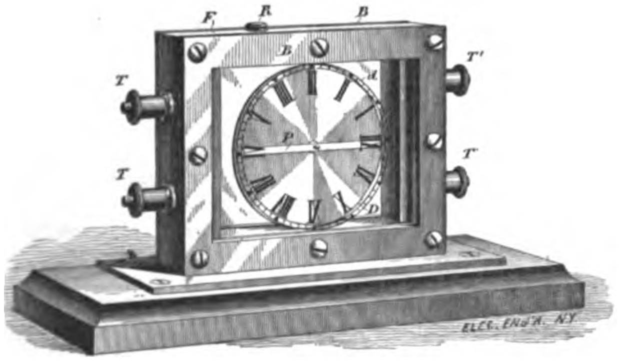
AN ELECTROLYTIC CLOCK.

BY

Nikola Tesla

If a delicately pivoted and well-balanced metal disc or cylinder be placed in a proper plating solution midway between the anode and cathode, one half of the disc becomes electro positive and the other half electro negative. Owing to this fact metal is deposited on one, and taken off from the other half, and the disc is caused to rotate under the action of gravity. As the amount of metal deposited and taken off is proportionate to the current strength, the speed of rotation, if it be small, is proportionate to the current.

The first device of this kind was operated by me early in 1888, in the endeavor to construct an electric meter. Upon learning, however, that I had been anticipated by others, as far as the principle is concerned,[1] I devised the apparatus illustrated in the accompanying engraving. Here F is a rectangular frame of hard rubber which is fastened upon a wooden base. This frame is about ½ inch thick, 6 inches long and 5 inches high. On both of its upright sides are fastened thick metal plates which serve as the electrodes. These plates are held firmly against the rubber frame by the binding posts T T and T' T.' On the lateral sides of the frame are fastened the brass plates B and B,' respectivly, of the same shape as the rubber frame F. These brass plates serve to keep in place two plates of polished glass, and the vessel is hermetically sealed by placing a soft rubber washer under and above each of the glass plates. In this manner the plates may be screwed on tight without fear of breaking them.



TESLA'S ELECTROLYTIC CLOCK.

The plating solution, which in this case is a concentrated solution of sulphate of copper, is poured in through an opening on the top of the rubber frame, which is closed by a plug R.

In the center of the vessel is placed a light and delicately balanced copper disc D, the axis of which is supported by a capillary glass tube which is fixed to one of the glass plates by means of sealing wax, or other material not attacked by the liquid. To diminish the friction as much as possible, the capillary tube which serves as a bearing contains a drop of oil. The center of the disc should be equi-distant from both the electrodes. To one side of the axis of the disc is fastened a very light indicator or pointer consisting preferably of a thin glass thread. The glass plate next to this pointer has a circle with the usual hour divisions engraved upon it, as on a clock dial. This circle may be movable so that it can be put in any position relatively to the pointer. If the dial is not movable then a thin wire of annealed iron may be used as on a pointer. The wire should then be so placed that it is exactly in the centre of the solution. By means of a horse-shoe magnet the disc may then be rotated and set in proper position.

The copper solution being carefully poured in, and the plug R replaced, the terminals of a constant current battery are connected to the binding-posts T T', and from time to time the rotation of the disc is observed. A shunt is connected to the other two binding-posts T T', and by varying the resistance of this shunt, or other disc, the speed of rotation is regulated until it is made to correspond to the division of the dial; that is, until, for instance, one turn is made in 12 hours.

Obviously this instrument was not devised for a practical purpose. Neither will it be quite exact in its indications. There are certain errors, unavoidable from the principle; for instance, the friction, which cannot be completely overcome. But the device is interesting as a means of indicating time in a novel manner. It will, however, be found that by a careful construction, constant current, and a temperature compensator, it may be made to rotate with almost perfect uniformity. The current density should, of course, be very small to secure the best results, and the disc of about 3 inches diameter should turn once in 6 hours. It is probable that with a silver solution and a silver plate better results would be obtained.

It is very interesting to note the appearance of the solution and disc in such a narrow transparent vessel. The solution appears a clear blue, one side of the disc seems to be silver white in a certain position, and the other half is dark like tarnished silver. There is no line of demarcation, but the shades melt beautifully together.

OPERATING SUB-STATIONS BY THE MOTOR-DYNAMO SYSTEM IN BROOKLYN.

BY

W. S. Barstow

THE Edison Electric Illuminating Company of Brooklyn, during the fall of 1890, resolved to extend their territory for furnishing low tension light and power, by the erection of a second district station. After a careful consideration of the matter, it was deemed best to supply this new territory from their present first district station until a sufficient load was accumulated to warrant the expenditure necessary for the erection and maintenance of the second district station. For this purpose a large feeder, consisting of copper conductors of 1,000,000 circ. mils each was laid underground to a point two miles distant from the present first district station. From this point sub-feeders were laid, and these in turn were heavily bridged by the net-work of mains. A standard feeder is selected from one of these sub-feeders, and at the extremity of this the voltage is kept at a constant pressure. As the load increases, the voltage is necessarily raised at the station end of the large feeder so as to preserve the voltage at the extremity of the sub-feeder. The efficiency of this system of low tension long distance transmission depends on the cost of the loss in the main feeder compared with the increased operating expenses of a second district station. When the cost of the loss (in watts) in this transmission equals the operating expenses of a second district plant, then this plant will be erected and will be run until the cost of operating exceeds the loss in transmitting from the first district station. It has been theoretically calculated (and since proved by practical results) that 1,000 amperes can be transmitted before the starting of the new station is necessary.

After the plans of underground feeders had been fully developed, attention was turned to the mode of generating this transmitted current. As the first district station is supplied with auxiliary busses, it was a simple matter to operate one or more station units (300 h. p. Ball compound non-condensing engine and two No. 32 Edison generators), on an auxiliary bus and connect the main feeder to it; but when it was taken into consideration that the new district load at certain portions of the day would not be more than 50 h. p. the efficiency of a large station unit became evident.

---

[1] The same invention is attributed to J. T. Sprague and T. A Edison.

After due consideration it was decided to operate the generators supplying this feeder by a motor, which, in turn, would be supplied by the bus of the first district station. A 50 h. p. C. & C. motor with pulley at both ends of the armature shaft was installed and connected to the station bus, and from this were belted two No. 6 Edison compound generators. This plant shows an average commercial efficiency of over 75 per cent. while the efficiency of the large station, by reason of the extra motor load, is increased over 10 per cent. The advantage of this arrangement can be better appreciated when it is known that, on a station unit, the loss of power due to engine friction and belting on an average load of 224.9 h. p. (at the engine) is 33.5 h. p. Should the load on the engine average 50 h. p. the low efficiency of the unit can easily be appreciated. The question of installing a smaller engine was contemplated, but on close investigation the idea was abandoned in favor of the motor.

The mission of this motor-dynamo plant is nothing more than to transform the bus pressure of the first district station to a variable pressure required at the station end of the large feeder in order to maintain a constant pressure at the standard sub-feeder extremity. Should the pressure on the station end of this main feeder equal the bus pressure of the first district (on account of light load), the little motor-dynamo plant is shut down, and the feeder thrown on to the station bus. Should the load exceed the capacity of the little plant, it is then of such proportion as to render the larger station unit efficient. One favorable point in this transmission system is that no extra help is required, the men usually employed in operating the large station easily taking care of this slight increase.

Work was commenced on this system on about October 15, 1890, and before December 1 a system of mains and feeders (capacity 2,000 16 c. p. lamps) was supplying 500 16 c. p. lamps, 26 Ward low tension arc lamps and 10 h. p. in motors. On April 1, 1891, there were connected to this system 2,000 16 c. p. lamps, 58 arc lamps, and 65 h. p. in motors. The little motor-dynamo plant furnishes current from 2 a. m. to 6 p. m., a station unit from 6 p. m., to 11 p. m., and the station bus from 11 p. m. to 2 a. m. Until the evening load was sufficient to be carried on a station unit, this motor-dynamo plant was in operation 21 hours per day and seven days per week.

When the new second district station is started, the main feeder will serve as a tie line between the two stations, so that either can be shut down during a light load to save operating expenses.

Among the many consumers in this district there is one who is operating one motor of 25 h. p. and two of 10 h. p., which are supplied with current at a point two and three-quarter miles distant from the little transmitting plant.

SUING HIS RIVALS FOR SLANDER.

Jacob H. Shay, a stockholder and salesman for the Charles Munson Belting Company, began suit last week for $20,000 damages for slander, against James Moloney, president, and John M. Thomas, secretary of the Chicago Belting Company, a rival of the concern in which Shay is employed. Shay charges that the two defendants circulated a story that he (Shay) had a monopoly of the belting trade with the Thomson-Houston Electric Light Company, because he had subsidized the purchasing agent of that company, one Sunny, and had bribed the latter with $50, for which Sunny gave all the belting work to Shay. The latter declares that the charge was wholly untrue, and made to injure his reputation and trade.

REFORMS IN THE PATENT SYSTEM.

BY

Thomas Ewing, Jr.

The patent system has for many years encountered a powerful and growing opposition. A Federal Senator told the writer recently, that he was for wiping the act from the statute books. The Farmers' Alliance have demanded that the term of the monopoly be limited to ten years, and the agricultural classes generally are disposed to look upon the system as of a piece with the high tariff and the rest of that body of vast, and in their view at least, vicious class legislation which has destroyed their hopes for a generation. On no class does it bear so heavily; they are not inventors, and the rule which makes the individual user of a patented article, who has purchased it of an unauthorized seller, though in entire good faith, liable for infringement to the owner of the patent, has made them, disunited as they are, easy prey to the greed and fraud of unscrupulous patentees.

Unable to make their opposition felt at any other point, the enemies of the system have resolutely opposed, and in large measure defeated, all attempts to extend and improve the Patent Office. The work of the office is rapidly increasing in quantity, while the growth of the arts makes investigation of the individual invention more and more difficult. Against 13,947 patents issued in 1880 there were 25,321 in 1890. A discovery is announced, and, almost before the sun is set, the office is flooded with the inventions of claimants who have applied the new principle. One is reminded of the lines in Hiawatha, which describe trouble as coming like birds of prey on a carrion:—

> "First a speck and then a vulture,
> Till the air is dark with pinions."

About 900 applications for patents are filed every week. Almost all the applications, as filed, contain claims that are anticipated in the arts, and in some cases many official actions and responses by the applicant are exchanged before an agreement as to the proper scope of the invention is reached. All this large and difficult work is dispatched by a force of examiners numbering less than 200, the personnel of which is rapidly changing.

No one unacquainted with the task can form an adequate conception of the difficulty of a fairly complete search. The skillful searcher must possess the insight of an inventor, and, looking beyond the utility disclosed, discern all other uses to which the invention could be put, that he may know in what outlying classes to look for anticipating devices. Some of the rejections made by the office, though sound in principle, seem rather ludicrous; for example, an electroplater's rack, described as consisting of two resilient bars of metal joined with a spring at one end and a clasp at the other, anticipated by a common hair crimper.

Thus the Patent Office is in chronic need of increased force and, ever since the war, has needed better salaries. Here is the farmer's opportunity to wing his shaft. No increase of salaries has been allowed in 42 years, and almost every call for more men has been answered by flat refusal, or scanty allowance of the lowest grade of assistant examiners. It might be well for those who thus cripple the patent office to consider what they are really accomplishing.

A little reflection will show that, without touching a hair of the system of protection, they are merely introducing the British system of granting patents to all comers upon registration, for our system which contemplates the granting of patents only for inventions ascertained to be new and useful. But while thus approaching more and more nearly the British system, we omit its safeguards. If the British patentee claims more than he is entitled to, his patent is invalid, but under our law only the claim that is too broad falls. Multitudes of patents are issued which might easily be found to have been anticipated in whole or in part upon careful search. Once issued they become difficult to defeat. Prior use must be established beyond reasonable doubt; and suits over valuable patents are apt to be merely contests for a share of the spoils of the monopoly. In the early telephone suits the opinions of Judge Lowell in the Spencer case, and Justice Gray in the Dolbear cases both state that the defendants admitted that Bell was the first inventor of the telephone. When this statement is contrasted with the assertion in the recent authoritative work of Messrs. Preece and Maier on the telephone, that Reis's telephone constructed 15 years before Bell's, "contained the essential features of the present telephone and certainly did transmit speech," it becomes plain that the one possible defence in which the public was largely interested, viz.: the anticipation of Bell by Reis, was waived. Where plaintiff and defendant agree, the public are counted out; for, though a party in interest in every suit to enforce a patent, they are not represented. If the patent office were thoroughly organized and equipped to conduct adequate searches before patents are granted, it would be a powerful agent for the protection of the interests of the public—an agent which the British system entirely lacks.

But there are defects in the administration of the patent office which render it an inefficient guardian of the interests of the public. Anxious to escape the imputation of hostility to inventors, and constantly importuned by solicitors seeking the broadest patents which the inventions disclosed will possibly warrant, many examiners are disposed to resolve all doubts in favor of applicants for patents, since the claims allowed, if too broad, can be declared void by the courts. But, as pointed out, the public are not represented in the courts, and the office jeopardizes their interests whenever a claim is allowed which a court should not sustain.

Again, the work of the office should be more rapidly dispatched.

It may seem a hopeless task to attempt this reform, when it is recalled that the ministers of the law were distressingly behind with their work in Hamlet's time, and have not caught up yet. But the fault in this case lies with the law rather than its ministers. There are a few vicious sources of delay which can be readily removed by legislation.

Under the present law, an applicant, in prosecuting his application for a patent, must answer each requirement of the office within two years of the date thereof. This liberal allowance of time, though necessary in some cases, where the citation of analogous inventions necessitates elaborate experiment and inquiry by the applicant, is, in a great majority of cases, excessive, and particularly where the invention has been tested by extensive commercial use. When, however, the aim of the prosecutor of the application is to consume time, claims are inserted which the office must reject, and two years allowed to elapse after each official action before reply; or an interference contest, like that of Edison and Berliner, both sides of which are owned by the American Bell Telephone Co., as stated in The Electrical Engineer of April 15, is fought to the bitter end by the single party in interest.

Thus the life of an application can be extended indefinitely. But the patent, when finally issued, runs for 17 years from the day of issue.

If the time within which response to official action may be made without explanation of delay were reduced from two years to something like two months, and the statute were to declare that where it appears upon the face of the record, or is clearly established, that the life of the application has been prolonged for the sake of delay, the patent shall be refused or declared void, this abuse would, in large measure, disappear.

The extension of the Patent Office, which all who deal with it so earnestly desire, can be accomplished as the result of a compromise. If those interested in the patent system will consent to the removal of existing abuses, its enemies can hardly stand so completely in their own light as to refuse to make the office an efficient public servant. This accomplished, the system of industrial protection, which has benefited us so greatly during the past century, may continue to bless us for centuries to come.

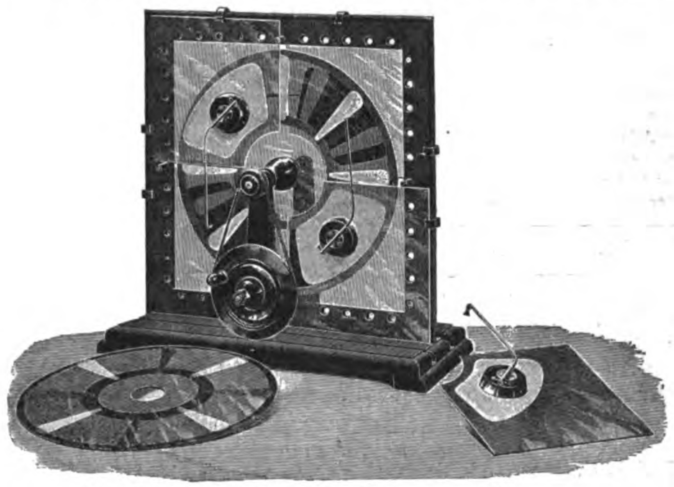
WIMSHURST'S ALTERNATING INFLUENCE MACHINE.[1]

A remarkable feature of this new machine is that while it gives an abundance of sparks, it is impossible to charge a Leyden jar, or similar contrivance, from it.

The conclusion is therefore forced upon us that the current of sparks is really the oscillation of a small charge, which flows backwards and forwards with great rapidity between the machine and the jar. The electricity that is developed is alternately positive and negative, and the normal condition of the jar is not upset.

Commencing to turn the disc exceedingly slowly, say, at the rate of three or four revolutions per minute, the leaves of the electroscope suddenly diverge, being repelled from each other. They remain apart quite steadily until the disc has made rather more than three-quarters of a revolution, when they suddenly approach and cling together, showing that the sign of their charge has changed. They remain thus for an instant, and during another three-quarters of a revolution they again separate, and so on. But if the disc be turned rapidly, the leaves are no longer able to respond in this way to the changes of charge.

The appearance of the machine is clearly shown in the accompanying engraving. A central spindle carries a glass disc 16 in. in diameter. This is varnished, and has affixed to it a number of sectors of tinfoil. The sectors measure 4 in. radially, while in breadth they may vary from ¼ in. to 5½ in. Usually the sectors on one side of the disc are arranged to break joint with those on the other side, but this is not essential. Indeed in many respects the construction of the machine is very elastic, and many modifications are introduced. For instance, the number of tinfoil sectors may vary from 2 to 16 or more, on each side, and, as we have said, their relative positions on the two surfaces of the discs are not important.



Wimshurst Alternating Influence Machine.

The disc itself is mounted in the centre of, and in the same plane as, a wooden frame 20 inches square. This frame carries four inductors of the shape shown in the detatched view; they are 9¾ in. square, with one corner cut away to admit the spindle and boss of the disc. Two of the inductors are mounted on each side of the frame, at opposite diagonal corners; those at the side of the machine nearest the spectator are, say, at the upper left hand and the lower right hand corners. At the opposite side, the inductors are at the upper right hand and the lower left hand corners. Upon each inductor plate is a tinfoil patch of the shape shown, measuring 4 in. radially, and 7 in. circumferentially. Other inductors are provided, having upon them the smallest tinfoil patch practicable. Cemented over each patch is a wooden disc which on its face carries a bearing in which there rides a bent brass rod, having a plume of fine wires at its end, touching the glass disc at a point 90 deg. remote from the inductor, and opposite one of the inductors at the other side of the plate. The disc is thus touched on both sides in two places. It is driven by a cord from a small handwheel below, and revolves in the direction of the hands of a clock. To further vary the capabilities of the machine a bar of insulating material is made to carry two metal wire plumes at its ends, these having metallic connection with two terminals; this device takes the place of two of the inductors, and by its use a constant flow of electricity may be maintained.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, MAY 6, 1891. No. 157.

With a master's hand Faraday traced the strong broad outlines of the truth, and for fifty years philosophers have pondered on his facts and have made thousands of experiments, yet have failed to fathom their full significance.—Alfred M. Mayer.

EXPORT ELECTRICAL TRADE.

IT is evident that this country is destined to do a large export electrical trade before many years have rolled by—large not only in the aggregate of dollars but in the variety of articles listed. The protective policy, which still influences our commercial relations with friendly nations, lessens the market by rendering production more costly, but under a regime of Protection, tempered by Reciprocity, we may hope for much and secure not a little. The conditions of our electrical trade with Europe are pretty well-known and are fairly stable, for the reason that Europe can manufacture for herself very cheaply, and hence does not make much drain on us, except for inventions and models, but in Spanish America the demand for electrical apparatus is growing apace, and as yet comparatively little has been done to satisfy it. According to statistics compiled by the *American Exporter*, the electrical exports of the United States to Spanish America have been as follows:

1885	$191,961
1886	144,070
1887	171,701
1888	278,304
1889	398,067
1890	602,538

This is a most encouraging growth, but the latest figures to hand are even more satisfactory. During March the amount was $74,494, the value of 2,030 packages of goods, and during the first quarter of 1891 the total amount was $190,969, or more than any whole year up to 1888. If the same proportion be maintained throughout 1891, the year's electrical exports to that region will reach not less than $750,000.

We have reason to believe that the figure just named will fall below the mark. There is an active inquiry for electrical apparatus in Spanish America, and our friends to the South look more and more to this country as the place where they can deal best. We have, ourselves, been consulted twice this year in regard to two large electric railway plants for South America, and have the gratification of knowing that part of the apparatus for the first of them has been shipped this month. Other plans of the same nature are maturing, and it seems more than likely that in electric lighting, electric railroading and electric mining a large field is just opening up. In these departments, the contracts run up easily into large figures, and hence the exports of previous years, under the stimulus of closer trade relations, are apt to be doubled and trebled. It is to be borne in mind also that there is a large business to be worked up in miscellaneous articles of a smaller nature, which, when once known in the hot tropics and below the equator, will soon become household necessities.

ELECTRICAL BROOKLYN.

OUR contents this week happen to deal in an especial manner with the electrical interests of Brooklyn. One article illustrates and describes, in the language of a student, Mr. A. C. Boughton, the electrical work now being done so admirably at the Pratt Institute. Another gives an admirable idea of the fine new Excelsior plant just started in the Offerman building; while a third describes a novel and ingenious method of current distributionjust carried out successfully in Brooklyn, for the first time, by the local Edison Company. Evidently the big city across the bridge is well "in the swim" electrically speaking, and we are glad to note also that she is likely to have soon a complete system of electric railways. The old provincial tone of Brooklyn is still heard in the absurd objections and arguments urged by a handful of people, who on the same lines would oppose every single improvement and advance that the century has seen; but the Brooklyn public as a whole, intelligent, alert and full of pride in their beautiful city, appear to be well aware that with electric cars they make a step forward of enormous importance. Brooklyn will find in her new departure much the same benefits that have accrued to other great American cities. Take St. Paul for instance. In a recent editorial on the electric cars, the *Pioneer-Press* says that a return to horse cars would be simply intolerable. "It is an entire revolution in the methods and conveniences of street railway travel, and if ten years ago or even three we could have imagined in effect a system as convenient and as satisfactory as that which is now in full operation, we should have been willing to purchase it at almost any price." The *Pioneer-Press* goes on to show how safe, swift and pleasant electric car riding is, and closes with the remark that the change to it has been worth ten real estate booms to St. Paul.

We hope ere long to be able to quote like testimony from some of our Brooklyn daily contemporaries as to the results in their own wide-reaching city.

THE ECONOMICAL OPERATION OF SUB-STATIONS.

It has come to be recognized as a feature, not only of security but of economy in the operation of central stations that they should be combined by a system or network of conductors, wherever the conditions will permit of it. This is well brought out in the article by Mr. W. S. Barstow, which we print on another page. While the laying down of a large mass of copper such as that employed in the instance cited might, at first sight, appear ill advised, thorough and complete calculation proves the wisdom of this proceeding. The wasteful character of the steam engine operating at light loads, as in this case, showed the economy of operating dynamos of somewhat higher potential at the main station, driven by motors deriving current from the dynamos at the same station; this double transformation having been proved to be more economical on account of the high efficiency of both motor and generator than the operation of steam engines at sub-stations where the load is at present very light.

It is evident that the case cited is practically equivalent to the placing of a motor-generator at the sub-station, so far as the current itself is concerned; but by placing the motor and generator at the main station, the items of operating expenses are reduced to a minimum, and the sub-station is freed from the necessity of attendance inseparable in the operation of moving machinery.

We cannot dwell too strongly upon the necessity of submitting all problems of this nature to a thorough analysis before proceeding to actual work; and we believe the method pursued by Mr. Barstow might be found profitable in many other instances.

Patent Office Reforms.

The interest that electrical inventors take in the patent system is very natural, in view of the fact that but for the protection thus afforded, invention in the electrical field would cease. Hence we are all concerned to know just what the opposition to the patent system amounts to, and first what reforms, if any, are necessary, so that the bulwarks may be strengthened. Mr. T. Ewing Jr. has a clever and thoughtful article on the subject in this issue, and having been not long since himself an examiner in the Patent Office he speaks with fuller knowledge. The suggestions and criticisms he makes should help towards a clearer understanding of the questions involved.

The Underground Situation in Baltimore.

A situation which, as far as we know, is absolutely without parallel, has arisen in Baltimore in regard to placing wires underground. An appropriation of $50,000 having been made by the city council to put the fire alarm wires in the new telephone conduits, Mayor Davidson has opposed the expenditure on the ground that the city should wait until a complete, general system of conduits is available. Mayor Davidson can certainly claim the glory of being the first American mayor who didn't want to put the wires underground "right off," and we can only regret that the point of objection is not a better one. Baltimore or any other city will have to wait a very long time before a general, ramifying system is available, so that every telegraph and telephone wire can go into it, no matter where it runs; and the experience in New York goes to show that the fire alarm telegraph wires work to thorough satisfaction underground. Superintendent Smith is so well pleased that he is extending the underground service all the time with the aid of the telephone conduits, and we cannot but think that the modest outlay proposed in Baltimore would be a good investment for that city.

Protection Against Lightning.

The paper by Mr. N. D. C. Hodges, printed in this issue, on his new system of protection against lightning, adds some details to the description we gave of his ideas and methods two or three months ago. Mr. Hodges, having noticed that certain conditions and results attend a lightning stroke, has come to the conclusion that what is wanted is a protector that will dissipate the charge by means of its own dissipation. Such apparatus as he proposes would evidently be cheap, and there should be no difficulty in finding out whether the Hodges device is a protector that protects.

Electro-Static and Electro-Magnetic Induction.

While the paper by Mr. J. J. Carty, read before the American Institute of Electrical Engineers, based as it was on the results of actual experiments, left little doubt as to the comparatively larger influence of electro-static induction upon telephone circuits, as compared with that of electro-magnetic induction, the exact numerical details of the experiments undertaken to demonstrate this fact were wanting. During the discussion of Mr. Carty's paper, Mr. A. E. Kennelly showed briefly that, on theoretical grounds, Mr. Carty's deductions were well founded. Not satisfied with this, however, Mr. Kennelly has now undertaken the series of experiments which he details in another column, and which prove conclusively the points for which Mr. Carty contended and for which due allowance must now be made in practical telephony.

Alternating Influence Machines.

While the generators of static electricity have now and again undergone some changes in their details of construction, those heretofore employed have been designed only for the production of electric charges of the same polarity. Probably the most efficient static machine thus far designed is that of Mr. Wimshurst, and to his already admirable work, this gentleman has now added a machine which generates alternating static charges and which gives rise to a number of curious phenomena. Our readers will also be interested in the machine described in this issue by Mr. Tesla, who has also sought to obtain alternating current by electro-static induction. Now that this subject has been brought into prominence, we shall doubtless see a variety of methods proposed for accomplishing the same object.

ALTERNATE CURRENT ELECTRO-STATIC INDUCTION APPARATUS.

BY

Nikola Tesla

About a year and a half ago while engaged in the study of alternate currents of short period, it occurred to me that such currents could be obtained by rotating charged surfaces in close proximity to conductors. Accordingly I devised various forms of experimental apparatus of which two are illustrated in the accompanying engravings.

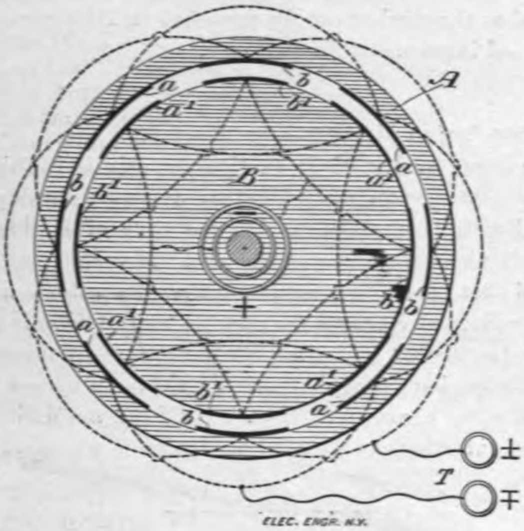

FIG. 1.—TESLA ALTERNATING ELECTROSTATIC INDUCTION APPARATUS.

In the apparatus shown in Fig. 1, A is a ring of dry shellacked hard wood provided on its inside with two sets of tin-foil coatings, *a* and *b*, all the *a* coatings and all the *b* coatings being connected together, respectively, but independent from each other. These two sets of coatings are connected to two terminals, T. For the sake of clearness only a few coatings are shown. Inside of the ring A, and in close proximity to it there is arranged to rotate a cylinder B, likewise of dry, shellacked hard wood, and provided with two similar sets of coatings, a^1 and b^1, all the coatings a^1 being connected to one ring and all the others, b^1, to another marked + and —. These two sets, a^1 and b^1 are charged to a high potential by a Holtz or Wimshurst machine, and may be connected to a jar of some capacity. The inside of ring A is coated with mica in order to increase the induction and also to allow higher potentials to be used.

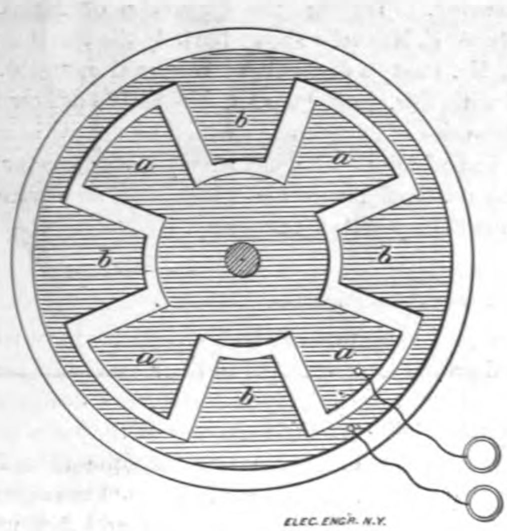

FIG. 2.—TESLA ALTERNATING ELECTROSTATIC INDUCTION APPARATUS.

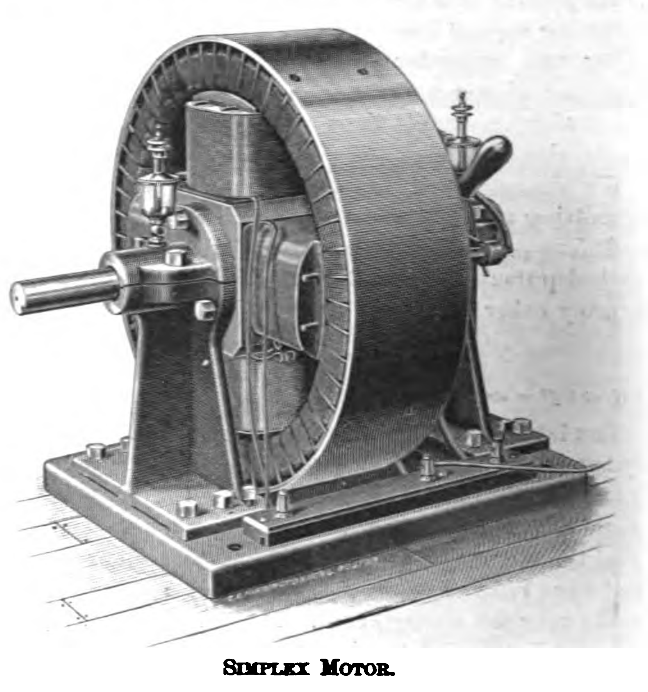
When the cylinder B with the charged coatings is rotated, a circuit connected to the terminals T is traversed by alternating currents. Another form of apparatus is illustrated in Fig. 2. In this apparatus the two sets of tin-foil coatings are glued on a plate of ebonite, and a similar plate which is rotated, and the coatings of which are charged as in Fig. 1, is provided.

The output of such an apparatus is very small, but some of the effects peculiar to alternating currents of short periods may be observed. The effects, however, cannot be compared with those obtainable with an induction coil which is operated by an alternate current machine of high frequency, some of which were described by me a short while ago.

THE SIMPLEX MOTOR.

A new motor presenting in its general appearance a contrast to those now in general use, has recently been brought out by the Simplex Motor Company, of Boston, and is being exhibited at their office at No. 113 Devonshire street, in that city. As will be seen from the accompanying illustration, the armature is placed on the exterior of the field, the coils of which are held in place by pins. The field magnet cores project through the coils to decrease the air space in the magnetic circuit. The armature, being in the form of a ring, can be extended to any diameter, will run at a very slow speed, and, therefore, produces little friction on the bearings.



SIMPLEX MOTOR.

The Simplex motor can be applied to vehicles in several ways, either directly, by making the motor a wheel of the vehicle, or it may be suspended from the vehicle and directly connected to the axle, or it may be mounted in the cab of a locomotive, and connected to the axle by means of side bars, as in the steam locomotive, or by belting, the advantages of this method being that the motor is high from the ground, and is thus protected from moisture and dust, while at the same time, every part is open to view and as accessible as though it were stationary and located in the shop.

The first two of these methods involves no loss whatever in the transmission of power, and the last, only a very slight loss.

THE EXCELSIOR PLANT, OFFERMAN BUILDING, BROOKLYN.

Offerman Building, Brooklyn.

ONE of the most striking and beautiful of the new edifices in Brooklyn is the Offerman Building on Fulton street, just above the City Hall, erected for and now occupied by the enterprising dry goods house of Wechsler & Brother. As those who are familiar with Brooklyn, know, the popular stores there clustered down near the ferry until a few years ago; but the growth and drift of the city has carried trade into higher Fulton street, where palace after palace has risen to ornament and dignify that thoroughfare. While in the old stores now being deserted, the electric light had already secured approval, in the new ones its great value and economy are so thoroughly recognized that nothing but a plant of the utmost perfection and efficiency will satisfy the proprietors of these huge establishments. Thus it happens that in the graceful and harmonious Offerman Building here shown, a plant has been installed which is without question the largest and finest of its kind in the city, and probably for its special purpose the most complete in the country. The owners may well be proud of it, and one need not be surprised to find it taken as a model in other work of this nature about to be attempted.

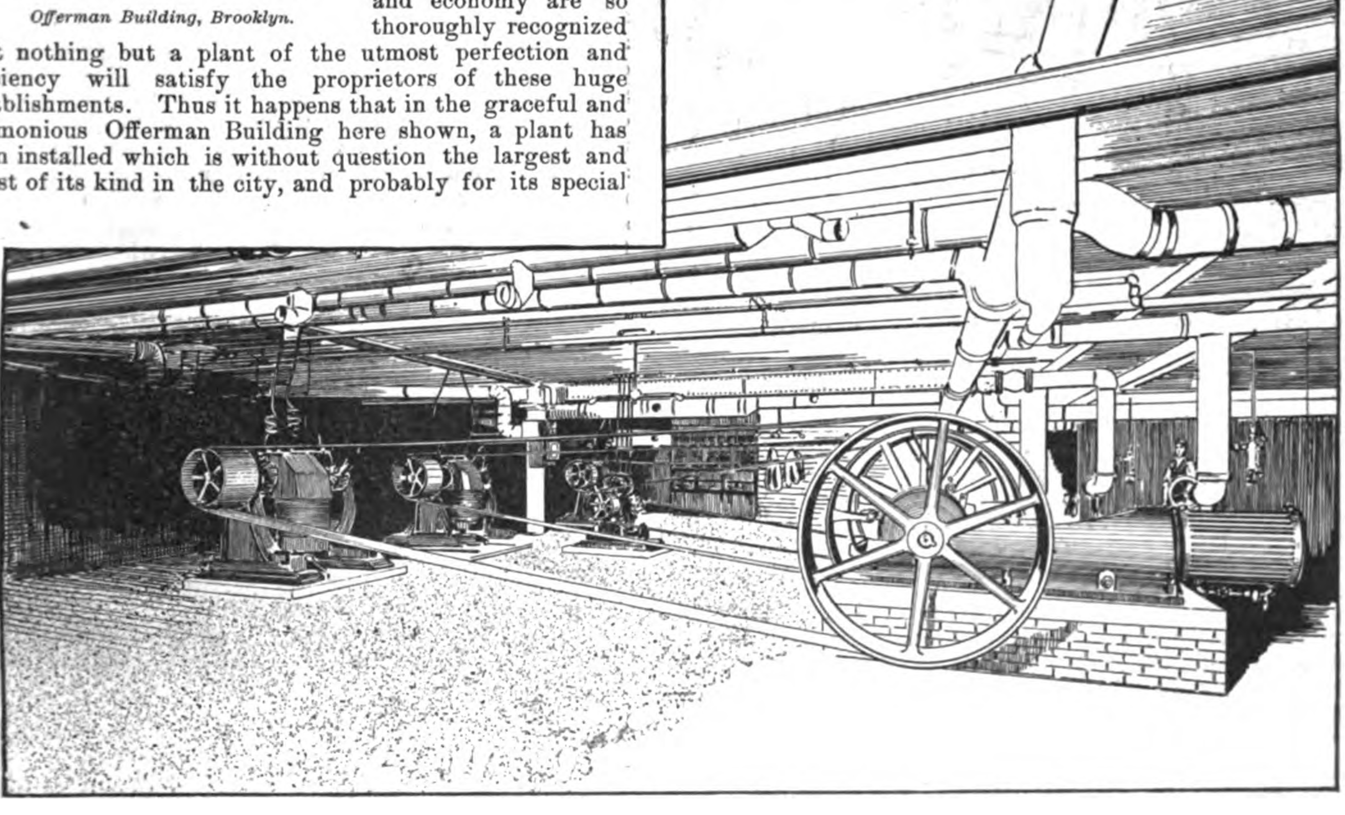


FIG. 1.—DYNAMO ROOM, EXCELSIOR PLANT, OFFERMAN BUILDING, BROOKLYN, N. Y.

This isolated plant has been installed by the Excelsior Electric Light Co., a Brooklyn concern which if it had no other achievements to point to could rest very comfortably on its local laurels, as the building is only the latest of a long series in Talmageville to receive equipments from Mr. Hochhausen. A view of the dynamo room is shown in Fig. 1. It occupies a large portion of the sub-basement, stands on solid masonry, and is so arranged as to admit of extension at any time. There are now installed three Excelsior incandescent machines of 600 lights each, the output being 350 amperes at 110 volts for each dynamo. These machines, and an Excelsior arc machine giving 30 lights of 2,000 c. p. each, are driven by three Ball automatic high speed engines of 65 h. p. each, steam to which is furnished from 4 Vogt Bros., 120 h. p. steel boilers. All the dynamos are thoroughly insulated from the base and ground.

From the dynamos the circuits are carried to the handsome switchboard shown in Fig. 2. Thence the circuits run to a separate switch on each of the 7 main floors. The switchboard has its full complement of ammeters, voltmeters, etc., and all the switches are carbon break, the disposition being extremely convenient and safe.

The building is now wired up for over 2,000 incandescent lights. The wires used for these is Grimshaw white core, laid in the walls. The arc wires are carried on insulators. A very effective disposition has been made of the incandescent lights, some 1,800 of which are grouped on handsome chandeliers distributed liberally on each floor. One very successful effect is obtained in the domed court which occupies the central space of the building, and has at each floor a gallery around it from which one can survey the brilliant, shifting throng below. On the ceiling of each floor, around the gallery rim, are placed some 40 or 50 lamps, and these when burning make a series of glittering concentric rings of light. The scene as one's glance travels through these narrowing constellations up to the sparkling dome that crowns the rotunda, is not easy to surpass in its grouping and color. Elsewhere, as in the glassware department and the boudoirs and salons, a most skillful and charming disposition of the lights has been made, each lamp being utilized to its fullest capacity for effective service in illumination whether of nooks and corners or of broad floor spaces and passages.

It may be added that the utmost care has been exercised in every detail of the installation, no pains or expense being spared by the Excelsior company to sustain its high reputation, and to give the building a plant of the greatest possible economy and efficiency in operation. The plant has already been started well up to its capacity and is running so smoothly and steadily that the soft gleam of the lamps is the only sign of its existence.

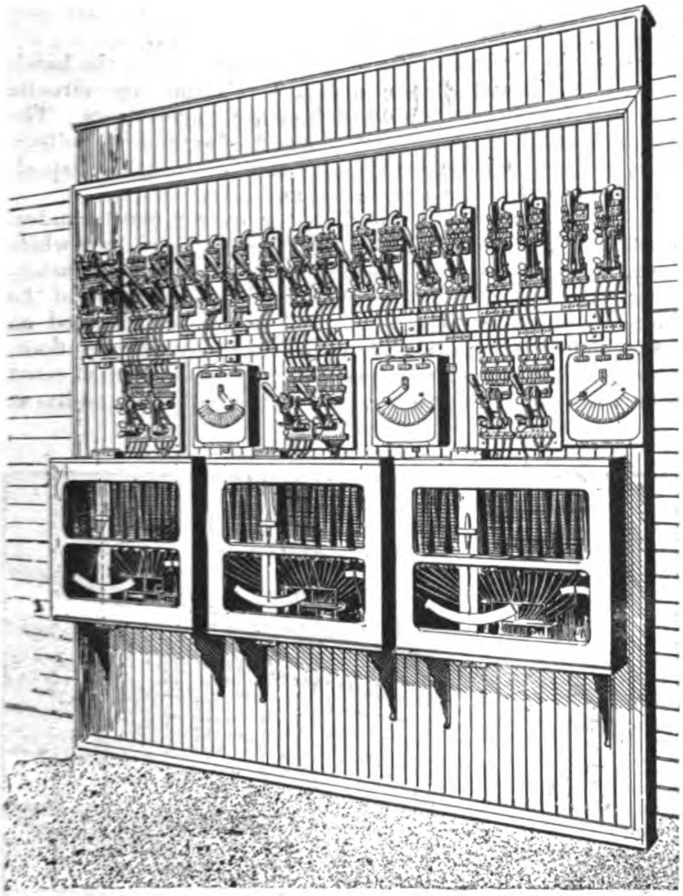

FIG. 2.—SWITCHBOARD, EXCELSIOR PLANT, OFFERMAN BUILDING.

THE WEST END PFINGST MOTOR CAR.

The West End company of Boston, in order to test the relative efficiency and economy of operating their cars by two motors mounted on the truck in the ordinary manner, or of one large motor mounted in an independent car, have had constructed in their own shops an electrical locomotive or motor car which has been put in operation upon their lines.

This new machine was designed and built by Mr. L. Pfingst, master mechanic of the West End company. The car is not designed to carry any passengers.

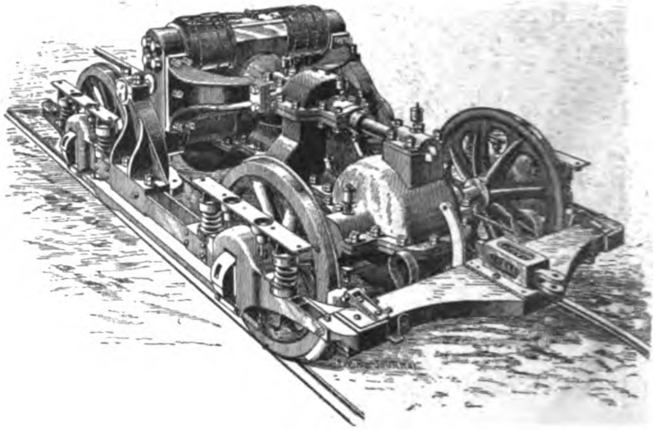
The accompaning engraving shows the method of gearing the armature to the axle, all the parts being unusually heavy in order to secure weight for traction and to insure durability. The motor is of the Siemens type and is calculated to develop normally forty h. p., the armature making from 1,100 to 1,200 revolutions per minute. At a speed of twenty miles per hour the armature makes 1,500. The commutator has seventy-two segments.

The fields are of the best wrought iron and are three feet three inches long, ten inches in diameter at the spools and twelve inches through at the pole. The field bobbins are wound with twelve layers of No. 9 wire, B. & S. gauge three loops being taken off at the sixth, eighth and tenth layer. All field connections are in multiple. The armature is fourteen inches in diameter and is wound with the double No. 8 wire, B. & S. gauge.

The power is transmitted to the intermediate shaft by a spur pinion on the armature shaft which in turn transmits the power to both car axles by bevel pinion and gear. The armature pinion is eleven inches in diameter and the reduction from armature to intermediate shaft is one to two and from the intermediate shaft to car axle one to four.

All the gears and intermediate shafts are entirely enclosed in oil-tight castings made of inch and a-quarter cast iron, none of the working parts being exposed except the commutator, armature and a portion of the armature shaft.

The following account is given of a run made on the evening of April 6, during which the readings were taken by Professor Hooper, of Tufts College, and Mr. Pearson, the electrician of the West End company. The run was made from the Bartlett Street stables of the company to the Tremont House, a distance of two and a half miles, and return, the return being made without a load. The outward trip was made with three cars in tow, each weighing six tons and loaded with thirteen tons of meal, a total load of forty-three tons. The run was made at a busy hour on the usual time of the ordinary cars. The only incident of the outward trip was the blowing out of a fuse while attempting to start on a grade crossing at Boylston Street. The capacity of the fuse was then increased, and the Tremont House reached without further trouble. The average flow of current for the trip with the load was sixty and nine-tenths amperes or thirty-six h. p. The maximum current used during the trial, including the grade, was 240 amperes. With a load of thirty tons the average current consumed, including down grades where train was in motion but had no current, was found to be about eighty-five amperes while the horse power used was 47.6. The maximum current was 350 amperes. This was consumed in starting after the car had stopped on a grade at a crossing. On the return trip, two and a half miles, when the car was running light the average current consumed by motor including down grades when no current was used was thirty amperes or eighteen h. p. A further exhaustive test will be made before it will be decided to operate all the cars in this manner, but another motor is already under construction which will embody such improvements as have been suggested by the operation of the one herewith illustrated.



WEST END PFINGST MOTOR CAR.

THE ELECTRICAL UTILIZATION OF NIAGARA.

The fifth annual report of the Niagara Falls Park Commissioners, presented the Ontario Legislature, in reference to utilising the power of Niagara Falls, says the Commissioners, with the consent of the Government, have made an agreement with a strong syndicate of English capitalists, the owners of large electrical works at Deptford, England, who have deposited $30,000. which is to be forfeited if the operations for the utilization of the power of Niagara Falls are not begun before March 1, 1892.

THE RUSSELL DISC CARBON ARC LAMP.

For some months there has been considerable interest shown in the Russell arc lamp, and as no complete descrip-of the lamp has as yet appeared, we give below the details of construction.

Fig. 1 shows the general appearance of the lamp, showing the disc carbon used for the positive pole.

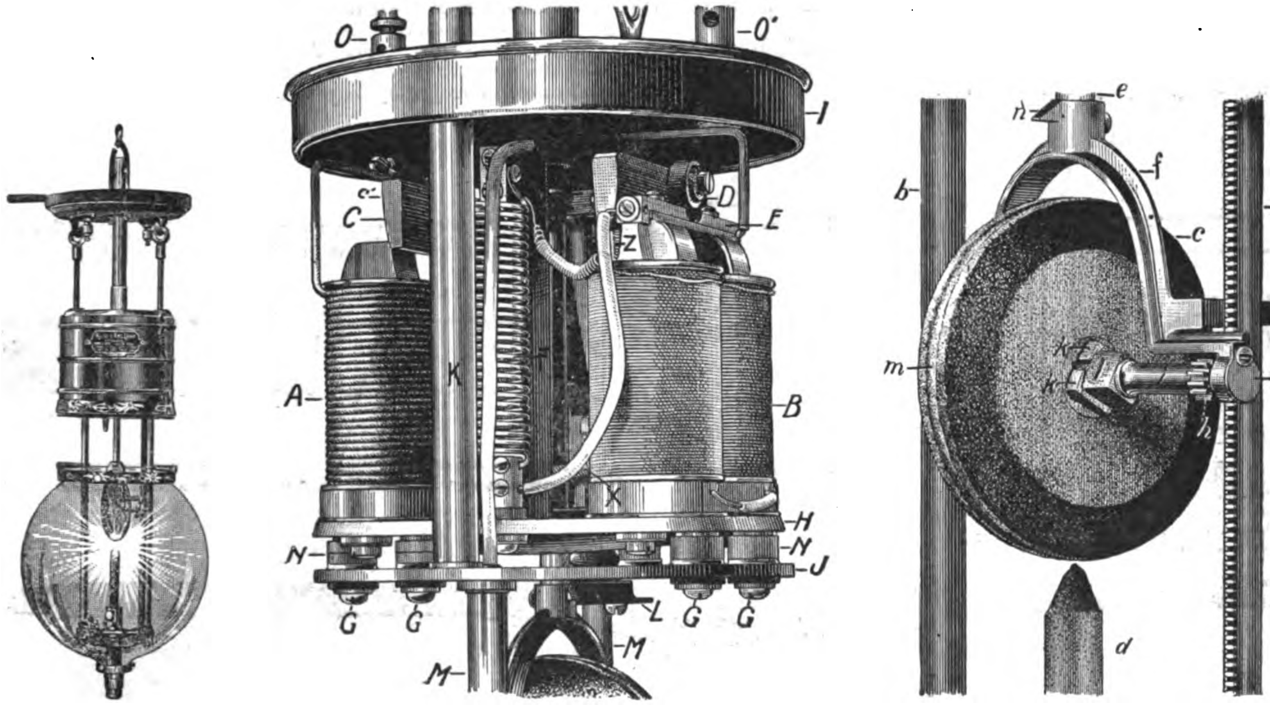
The action of the lamp will be readily understood by reference to Fig. 2. When the current goes through the series magnets, A, the armature C is attracted, which opens the cut-out E, by lifting out the metallic button D, and lifts the carbon rod by a link, and thereby strikes the arc. As the arc lengthens, its resistance is increased, and more current goes through the shunt magnet B, attracting its armature, and thereby allowing the carbon rod to drop a little. It will be seen that thus there is an electrical balance maintained at all times, between the two armatures, C and D, of the series and shunt magnets. The armatures are attached to the rocking lever by a small screw, which can be adjusted to bring the armature more or less into the field of the magnet, and by means of which a most delicate adjustment of the lamp can be obtained

Fig. 3 shows the details of the revolving feed for the disc carbon. The carbon rod *e* enters the socket *n* of the yolk *f*, which carries the spindle *i*, carrying a small pinion *h* gearing into a ratchet on one of the frames of the lamp *a*. The disc carbon is renewed by unscrewing the nut *l* which allows the two parts *k k* to contract, when the disc can easily be slipped off or on. The arc is maintained between the disc and the negative carbon *d*, and as the lamp feeds, the disc drops and is at the same time revolved by the pinion gearing into the rack, the lug *g* always keeping the pinion in close gear with the rack.

The Russell lamps develop 1,200 or 2,000 c. p. by actual photometer test, taking $6\frac{8}{10}$ amperes or $9\frac{6}{10}$ amperes, respectively, with an average voltage of 46 volts. They are made in four different sizes, to burn different periods of time. The lamp calculated to burn 8 hours is $32\frac{1}{2}$ inches long, and uses a disc carbon 3 inches in diameter; the 12 hour lamp is 35 inches long with a 4 inch disc: the 18 hour lamp is 42 inches long with a $4\frac{1}{4}$ inch disc; and the 24 hour lamp is 49 inches long with a $4\frac{1}{2}$ inch disc. The disc carbons are all $\frac{5}{8}$ inch thick, and the negative carbon is $\frac{5}{8}$ inch diameter, although smaller carbons can be used successfully.

The lamp is made of the best material and workmanship, and is all machine made, each part being interchangeable.

The lamp, we may add, is manufactured by the Russell Electric Co., of Boston, Mass.



Figs. 1, 2 and 3.—The Russell Disc Carbon Arc Lamp.

ON FURTHER CONTRIBUTIONS TO DYNAMOMETRY.[1]

The object of Mr. Blakesley's paper was, in the first place, to show what sort of physical quantities could be advantageously evaluated by using electro-dynamometers of two coils of low resistance in circuits conveying electric currents. The meaning of a dynamometer reading was explained to be the mean value of the product of two currents, either steady or alternating, or one steady and the other alternating, undergoing any periodic variations with sufficient rapidity. In mathematical language such an instrument measured $\frac{1}{T}\int_0^T C_1\, C_2\, d\, t$, where C_1 and C_2 were the instantaneous values of the currents in the two coils, including, of course, the common case where these currents are identical.

Any physical quantity whose value was such a product, $C_1\, C_2$, multiplied into something which was independent of the time, and which, therefore, on integration came outside the integrator, was well adapted to have its mean value given by such instruments. Power was such a quantity, being merely $(\text{current})^2 \times$ resistance. The square of an E. M. F. was another such quantity, but he did not wish to restrict the method to such evaluations.

It follows that any quantity whose instantaneous value can be expressed by terms each quadratic in current, and whose other factor was independent of time, could have its mean value expressed in dynamometer readings. In addition, the particular place and mode of coupling of the dynamometers was indicated by the instantaneous equation, as well as the factor to be applied to each reading. *Thus the equations are made to indicate the practical arrangements to be adopted, and the use to be made of the observations in each case.*

Examples were given for the cases of transformers in series and parallel, and special applications of the method were suggested in the measurement of the power employed in such diverse apparatus as voltmeters subject to direct or variable currents of any sort, welding machines, parallel generators, tuning-fork circuits, vacuum discharges and imperfect condensers. For parallel generators, the power of each could be separately estimated, and in the case of electric welders, the power employed in the welding circuit was shown to be measurable without introducing any resistance whatever into that circuit.

[1] Abstract of a paper read before the London Physical Society.

THE MULTIPLE DUCT SYSTEM OF THE INTERIOR CONDUIT AND INSULATION CO.

Our readers will remember the description, in a recent number of THE ELECTRICAL ENGINEER, of the single duct system of the Interior Conduit and Insulation Company. As a result of an elaborate series of experiments, this company has now produced a "multiple duct" system, details of which are shown in the accompanying illustrations. This consists of a series of highly insulating water-proof tubes, which form individual channels for the reception of whatever electrical conductors may be employed, thus providing for the drawing in, or withdrawal of, conductors at any time, and rendering them as accessible for renewal and repairs as if placed on the surface itself.

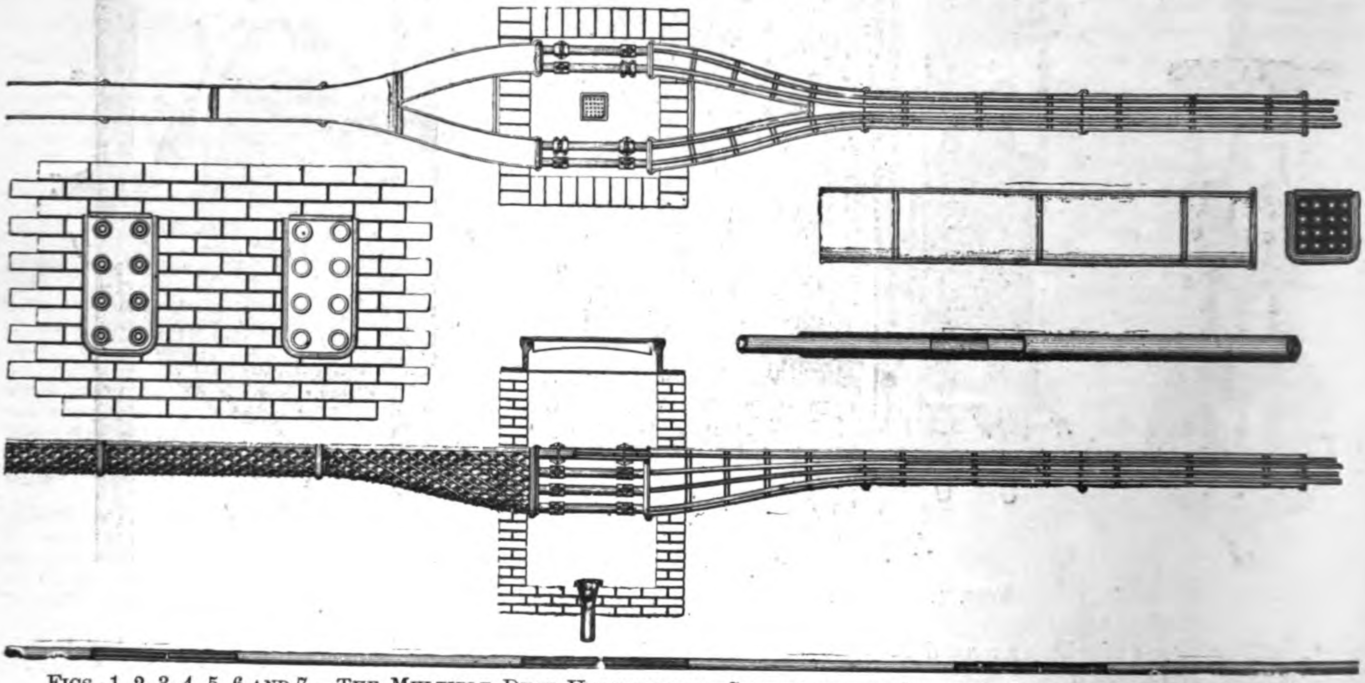
The conduits being composed of highly insulating material throughout their entire length, and being absolutely air tight and moisture proof, it is possible to employ bare copper conductors in place of the lead sheathings commonly used for underground work.

In its physical characteristics the multiple duct system differs from the ordinary iron, wood, cement and other conduits, in that, while they only contemplate ducts of uniform and large diameter, each accommodating a considerable number of wires, these conduits provide an individual duct, for each and every wire and cable employed. In the important element of insulation, however, it differs in a radical degree, as it provides in the conduit itself, without special investment, an insulation ample for all purposes.

The conduit may consist of any desired number of individual tubes or ducts continuous from one manhole to another, no joints or couplings being employed; thus a fruitful cause of leakage and consequent deterioration is eliminated. The method employed to convert the tube sections into continuous unbroken and unjointed ducts constitutes one of the important elements of the system. The general method is as follows:

A light cast-iron interlocking box Fig. 1 and 2, is first laid in the trench and a series of the company's telescopically formed tubes of any given number, length and diameter are then racked together within the iron boxing, so as to be held apart a uniform distance by insulating supports. The interstices between the individual tubes, and the tubes and boxing are then filled in with an insulating compound, composed for the most part of coal tar pitch, Fig. 3. This is poured in a liquid state and quickly solidifies, presenting a substantial body composed of a highly insulating material, through which run the clear straight duct interiors.

The telescopically formed ducts consist of two tubes, Fig. 4, one fitting within the other, the internal diameter of the smaller being just that called for by the requirements of the use to which they are put. At the moment of laying, the inner tube is coated with an insulating compound and then telescoped into the exterior tube to just one-half of its length; thus each duct so formed of two complete tubes cemented with a superior insulating compound, becomes, to all intents and purposes, a continuous unbroken tube, without sleeves or joints and possessed of very high insulating properties.



FIGS. 1, 2, 3, 4, 5, 6 AND 7.—THE MULTIPLE DUCT UNDERGROUND SYSTEM OF THE INTERIOR CONDUIT AND INSULATION CO.

The manhole, Figs. 5 and 6, is a simple construction of brick cemented to protect it, from the exudations of the soil, for the sake of cleanliness. The section of the general containing box or conduit entering the manhole, is expanded in a forked form and also in a vertical line, as shown in the accompanying figures, for the purpose of providing greater space around the duct ends for more convenient manipulation.

The end of each section entering the manhole is provided with a cast-iron head, on the face of which are short pipe projections, which are carried across the manhole to the opposite face plate by sectional iron pipes enclosing a section of the insulating tube. These sectional pipes are adapted for easy and quick removal in order to render the conductors readily accessible. Thus the continuity of each duct is preserved across the manhole, which may therefore be left open with impunity in all kinds of weather.

Lamp posts, feeder posts, elbows and other branch connections are so constructed as to be minor extensions of the system in its every feature. They consist of iron boxing or piping filled with insulating compound and joined to the conduit proper by elbow extensions, thus providing for the drawing in of the conductors from the nearest manhole.

THE ELECTROLYTIC GENERATION OF HYDROGEN AND OXYGEN.

In a paper recently read before the Société Française de Physique, Commander Renard described his investigations on the electrolysis of water on a commercial scale, which he commenced as far back as December, 1887. Taking the back E. M. F. at 1.5 volt, and the total plant efficiency at only 50 per cent., 35.3 cubic feet (one cubic metre) of hydrogen can be produced for every 10 horse power hours; and taking the coal consumption at 2.2 lb. (one kilogramme) per horse power hour, the cost of fuel for every thousand cubic feet at atmospheric pressure of the mixed gases comes out in France at between 45 cents and $1.20, according to the price of coal. To make the electrolytic production of these gases a commercial possibility, it is necessary to avoid the use of costly platinum electrodes and of airtight partitions for collecting the gases. Commander Renard employs an alkaline electrolyte (caustic soda, 13 per cent. solution) and is, therefore, able to substitute cheap cast-iron electrodes for platinum. As to the vessels for the collection of the gases, he finds that so long as they have a *capillary reaction* Δ equal to a few centimetres of water, the hydrogen and oxygen do not mix. Commander Renard employs porous pots of asbestos fibre, which are able to withstand a pressure of from 30 to 50 cms. of water without permitting the passage of the gases. The actual commercial apparatus used at the Chalais works is as follows: A large cylinder of common sheet iron serves at the same time as the containing vessel for the electrolyte and as the negative electrode. The positive electrode is a perforated iron tube, fixed on to an insulated lid, which fits hermetically on to the top of the containing vessel. This electrode is surrounded by a large asbestos bag. Two voltameters of this kind have been in continuous work at Chalais for some six months, and at the end of this period both the electrodes and the asbestos bag were in perfect condition. The gases given off are pure, and there is no ozone. According to Commander Renard a battery of 36 large voltameters could generate about 200 cubic feet of hydrogen and 100 cubic feet of oxygen per hour, which could be compressed to a pressure of from 120 to 200 atmospheres in steel tubes, and utilized for therapeutic, laboratory, metallurgical, and other purposes. The *total* cost of these gases, ready for use in steel bottles at a pressure of 120 atmospheres, when produced on a sufficiently large scale, is estimated at from $2.90 to $3.50 per thousand cubic feet.

THE PACKARD VACUUM PUMP FOR EXHAUSTING INCANDESCENT LAMPS.

WHILE the mercury pump leaves nothing to be desired as a method of obtaining a high vacuum, its employment in completely exhausting vacuum lamps is tedious and expensive. In order, therefore, to expedite and cheapen this important part of lamp manufacture, mechanical vacuum pumps are now extensively employed to remove the larger part of the air contained in the lamps, leaving the mercury pumps to complete the vacuum required. Probably the most extensively used vacuum pump for this class of work is the Packard Vacuum Pump, built by Mr. Norman Hubbard, of 93 Pearl street, Brooklyn, N. Y. Our engraving, Fig. 1, shows the No. 4 pump, and as will be seen, the cylinders are placed vertically in a cast-iron box which serves as a bed plate and water-jacket, and on which the frame and working parts are mounted. Each cylinder is entirely independent of the others and can be used separately or connected up as required. The suction pipes are connected at the bottom of the jacket by means of ground unions which are provided with traps to arrest any mercury or dirt, and the exhausts are piped to a pot which acts as a trap to catch the oil used in lubricating the cylinders, which is saved and may be used over again. No water is used in the cylinders.

The valve motion is on the principle of the well-known Ritchie valve gear, but containing none of its complication. All the valves are opened and closed automatically, not requiring an air pressure below them to do this work. The main valve stem does not pass through the piston head. The clearance in the cylinders is reduced to a minimum, being generally less than $\frac{1}{16}$th of an inch, and no liquid is used other than sufficient oil to insure proper lubrication.

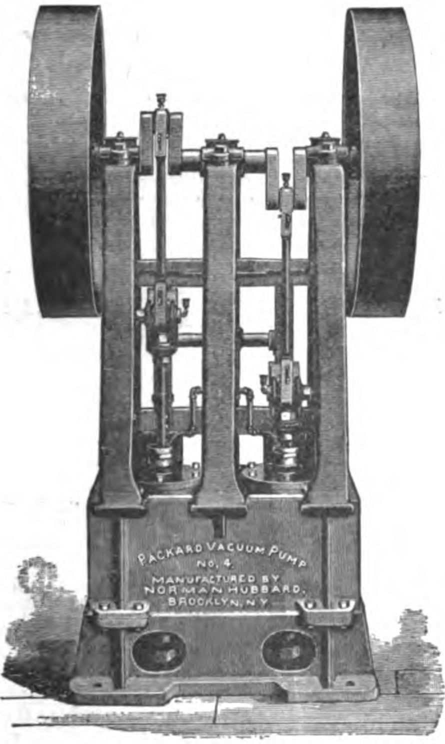


FIG. 1.—THE PACKARD VACUUM PUMP FOR EXHAUSTING INCANDESCENT LAMPS.

The valves in the piston head have their seats close to the bottom, and are entirely inclosed in the body of the piston, rendering impossible the breakage or giving out of the valve. The exhaust valves are contained in a separate bonnet bolted to the cylinder head. This bonnet has a screwed cover, by removing which the valves can be lifted out.

The company claim that (the barometer being at 30 inches) a vacuum exceeding 29½ inches is easily obtained.

The Packard pumps are built in a variety of sizes, the smaller ones being designed for the preliminary exhaustion of the lamps. The larger sizes are designed for the operation of the ordinary automatic Geissler pumps, where the mercury is raised and lowered by alternately admitting the atmospheric pressure and producing a vacuum above the mercury in the lower bulb. The method of connection of the Packard pump with the mercury pump is shown in Fig. 2.

These pumps are in regular use in every incandescent lamp factory in this country, with one exception; among them, in that of the Sawyer-Man Electric Co., where no less than 23 of them are in operation; the Thomson-Houston Electric Co. operate 19; the Perkins Electric Lamp Co., 10, etc. Not a few, also, are in use abroad, where their merits have been recognized.

LIGHTING THE HARLEM TUNNEL.

The New York Central Railroad has begun experiments with a view to lighting the tunnel.

The west-side rock-cut tunnel, through which its north-bound local trains run, has been lighted with incandescent electric lamps of about 40 c. p., placed alternately on either side of the track, about 125 feet apart.

Reflectors placed on the south side of the lamps prevent the glare of light from reaching the eyes of the engineer or fireman of approaching trains, and throw the light forward on the track.

The lamps are placed three and a half feet above the rails, and their light should not interfere in any way with the signal lamps, which are placed much higher.

It has been alleged, and denied, that the New York Central officials have tampered with the arrangements so as to make it appear that the lighting did more harm than good by blinding the engineers. There is not the slightest reason why these small incandescent lights, properly placed, should have the effect of blurring or rendering useless signal lights.

WONDERS OF ELECTRIC TRACTION IN WACO, TEX.

The Waco *Daily News* describes in glowing colors the system upon which the new electric railway in that town will be operated. According to this facetious exponent of the Sunny South, "the cars will run alone except the passengers." Should any one neglect to deposit his fare, an automatic monitor will run along a wire, extending around the car, and touch him gently but firmly on the elbow, while the words "pay your fare" will appear in a frame at the end of the car. If this warning be unheeded, the letters glow more and more fiercely, until they finally disappear in a jet of flame, and the name of the delinquent takes their place. At the same time a fiery ring fastens about his neck, and, despite his struggles, he is dragged to the rear platform and thrown into the street. In case the man is a dead-head, however, the monitor recognizes him at once, and the word "complimentary" appears in the frame.

The cars stop and start themselves automatically, and should anything get out of order, the trolley arm connects with a telephone wire, and explains the difficulty to the one man employed by the company at the central station, who hastes lightly to the scene, and all is well.

MR. MCCARTHY, late of the Thomson-Houston Electric Co's. railway department has joined the Westinghouse Co. as special electric railway agent.

ELECTRICITY IN MILL WORK.[1]

BY O. S. HUSSEY.

The province of this article is not so much the consideration of the subject of long distance transmission as it is to show, if possible, how electric power can be used advantageously in performing some of the work in and about a mill, now done by other means.

This work may be divided under the following heads:—1. Electricity as applied to isolated motors, located in different parts of a mill, and used to drive lines of shafting, separate machines, etc. 2. Electricity as applied to driving tram-cars suitable to handling all classes of goods both in the mill and about the mill yard. 3. Electricity as applied to hoisting machinery of all descriptions, including elevators, whip and drum hoists, etc. 4. Electricity as applied to pumping machinery.

Assuming that there is sufficient power at the mill, either steam or water power, let us then consider what is necessary in the way of generators for supplying power to the different electrical apparatus, wherever located.

For transmitting over distances such as would occur about a mill, both generators and motors should be wound for 500 volts, insuring economy in copper wire without danger to persons handling the apparatus, and each machine should be driven from the existing water or steam powers through the medium of a friction clutch. As a rough approximation, 100 feet of shafting, 3 inches in diameter, and making 120 revolutions per minute, requires 1 h. p. to overcome its friction, under conditions of fairly good alignment and good care. Should this shafting get out of alignment, as is frequently the case, its frictional resistance would be proportionally increased.

It has been estimated that from 30 to 50 per cent. of the power generated in mills and factories is unremunerative, because of the wasteful method of driving in vogue at the present time. Should a judicious arrangement of electrical transmission be employed, on the contrary, fully 85 per cent. of the power developed by the wheels would be expended in useful work. That the transmission and distribution of power by electricity is a profitable investment, is proven by the large number of electric stations scattered throughout the country. Not only can power be saved by electrical transmission, but also a large amount of space is made available for other purposes.

Another point which should be considered by mill men, and which would seem to be a very essential one, is this:—by a subdivision of shafting into small units, a much more complete control is had over it in case of accident or of any breakdown which is liable to occur, and which means, as mills are driven to-day, the shutting down of the entire room, and sometimes of an entire factory, at an immense loss while repairs are being made. On the other hand, should motors in small units be used, simply that portion of the room in which the breakdown occurred would be stopped, the rest of the mill running as before.

As an electric motor has but one running part, the armature, there is very little about the machine to get out of order, but should an accident happen to any part of it, this can, under ordinary circumstances, be quickly repaired.

Automatic regulation of speed of less than 2 per cent. variation is obtained on all first class motors, no matter what the variations of load may be. This feature is of special value, as it permits of the simplest possible construction of the motor, and at the same time secures an automatic regulation of speed well within the range of that which is guaranteed for the best regulated high speed steam engines.

The next head to be considered is the application of electricity for driving tram-cars The electric mill tramway, in its sphere, has operated fully as successfully as the electric street railway, although its adoption has not been so general. A mill tramway is practically a modified electric street railroad, the principle of propulsion being the same. Usually a single overhead trolley system is used, as in street railway work. Where the motor car is to be run inside of buildings, however, two trolley wires are used, in order to have a thoroughly insulated system throughout and to do away with any sparking which might occur between the rails of the track and the revolving car wheels.

The amount of power generally used by motor cars in ordinary tramway work is either of 3 or 6 h. p.; the former easily hauling a load of 5,000 pounds, and the latter a load of 10,000, exclusive of the weight of the car, at a speed of four miles per hour on a level and straight track.

For hauling heavy loads, such as loaded freight cars, electric locomotives of 30 h. p. and over have been designed. All these machines are so constructed that the platform of the machine itself is available for loading, if so desired. The small motor cars are built to operate on any gauge of track from 30 inches to the standard 4 feet 8½ inches.

The third head to be considered is the application of electricity for hoisting apparatus. For hoisting work, machines are now made of almost any size and power, from a 3 h. p. whip, suitable for handling light loads at a high rate of speed, to 80 and 100 h. p. machines for heavy work.

These hoists are particularly desirable for store houses and warehouses, because they can be mounted upon trucks and easily moved from one portion of the building to the other, wherever needed. A Thomson-Houston hoist is in use on one of the large docks in Brooklyn. The wharf is wired in all parts, plugs being inserted at intervals so that the supply of power can be obtained from the main wires at almost any point, and at a moment's notice. On Constitution Wharf, in Boston, a large 45 h. p. motor is used to drive an elevator and also a long line of shafting running the entire length of the building, from which four friction whip hoists are operated for handling light loads rapidly. These small friction whips should receive the approval of mill men for use in cotton, wool, or cloth storehouses. To-day, in a great many places, a dozen or more men are required to do the same amount of work that two men with a whip hoist could perform more quickly and easily.

Within the past year electricity has been applied successfully to elevators, and special machines have been designed for this work. The hoisting drum is mounted upon the same bed plate as the motor, and is driven by means of worm gearing. The worm-shaft is connected directly to the armature shaft by a coupling, insuring positive motion between the motor and hoisting drum.

The fourth and last head to be considered is the application of electricity to power pumps. While this question may not have so much interest to mill men in general as the previous points brought up, still it may be of sufficient interest to warrant the mention of a form of pump which is being used to a great extent by the Thomson-Houston Motor Co. in connection with it motors. This pump is manufactured by the Goulds Manufacturing Co., of Seneca Falls, N. Y., and is of the triplex single acting type. Three single acting plungers, with their cranks hung from the main shaft at 120 degrees, are worked in three vertical cylinders. This arrangement is the best for electric work, as it insures an almost constant load upon the motor at all points of the stroke. The Goulds Manufacturing Co. makes pumps of this design in all sizes from 2x4 inch cylinders for light work to a 12x12 inch in course of design The efficiency of these electric pumps has been shown by actual test to be fully equal to that of a steam pump of corresponding capacity, and working under similar conditions.

Electric pumps are intended to supersede steam pumps of any size, particularly if the location of the pump is any great distance from the source of power. With the efficiency the same, the electric pump can be operated much more economically, owing to the small loss in power in transmitting electricity, as compared with steam at an equal distance.

The electrical system of power distribution in regular work permits of the utilization of water powers situated at distant points, and in the absence of water power, renders a concentration of the steam plants possible.

[1] Extract from paper read April 29th, 1891, before the N. E. Cotton Manufacturers' Association.

NOTES ON THE DESIGN OF MULTIPOLAR DYNAMOS.[1]—I.

BY W. B. ESSON.

PREVENTION OF SPARKING IN MACHINES GENERALLY.

From the data furnished by a large number of examples, some of which were given in the paper which I submitted for your consideration twelve months ago, an expression for the load which could be safely carried by armatures without causing sparking was obtained; this expression, though admittedly of an arbitrary character, having been proved by my own experience and that of my colleagues, to have been of some service. In that paper the term "ampere-turns" was employed to denote the product of the number of conductors on the exterior of the armature and the current carried by each, and I am afraid this may have led to some confusion; at least, so it appears from the discussion. In order that there shall be no misunderstanding in the present case, I shall call this product, quite irrespectively of the number of poles, the *volume* of current carried. The volume is therefore the total current flowing parallel to the armature shaft, independently of direction and whatever the number of poles, and it is obtained by multiplying the conductors on the exterior of the armature by the current flowing in each; or, considering the exterior winding as a copper cylinder, it is the total current flowing in its parallel to the axis.

In his paper on "Armature Reactions," read here last year, Mr. Swinburne had worked out the limiting load from a theoretical point of view, and those who were present will remember that to obtain the results given in his paper the author assumed that the brushes were placed almost close to the polar tips. For the moment, however, it will be assumed that the brushes are somewhere near the pole-tips—in their vicinity, let us say—and that the only conductors concerned in producing the cross field are those covered by the pole-pieces. This is sufficiently near the truth for our purpose. Under these circumstances the magnetizing force in ampere turns producing a cross field is, of course, $\frac{v\,\varphi}{360}$ where v is the volume, and φ the angle embraced by each pole-piece in degrees. Call l the length of the air gap, measured from the surface of the armature core to the polar surface, and I the induction per square centimetre which would be produced in the gap due to the field magnets alone. When a current flows in the armature the field is weakened at the pole-tips nearer the brushes and strengthened at those farther from them. Imagine that the armature is loaded so that the forward induction under the nearer pole-tips is just balanced by the cross induction, and we have $\frac{v\,\varphi}{360} = 2l \times .8\,\mathrm{I}$, assuming that the components of the cross circuit, other than the air gap, have no resistance. According to this equation, with a value $v = \frac{576\,l\,\mathrm{I}}{\varphi}$ the forward and cross induction at the pole-tips would be equal, the field would be *nil* at the brushes, and the machine being unstable, any increase of current would at once cause great sparking.

---

[1] Abstract of a paper read before the Institution of Electrical Engineers.

THE RELATION OF *v* TO THE DIAMETER OF THE ARMATURE.

But besides taking care that the armature load does not approach the sparking limit, we must provide ample surface for getting rid of the heat generated in the conductors. The first thing to be settled in designing a new machine is what this amount of heat shall be; or, in other words, we must fix the ratio which the energy appearing at the terminals shall bear to the total electrical energy produced. Having settled this, sufficient radiating surface must be allowed to prevent too great a rise in temperature—a point to which due consideration has already been given.

The principal factors which determine the relation of the volume to the diameter of the armature are efficiency and temperature. To carry a given volume we must have, consistent with the with the waste of power permissible, a certain section of copper; and this copper should be disposed so that a cooling surface is provided sufficient to keep the rise in temperature within the specified limit, while the gap, being of sufficient length to prevent sparking, should have only the dimensions necessary for accomodating the conductors and allowing of proper clearance.

Though the relation lacks definiteness to some extent, I find in the data of a large number of machines, indications sufficiently pronounced to justify us in regarding the volume carried by the armatures of two-pole dynamos as proportional to the diameter for all sizes. In designing cylinder machines the value of v may be taken as 400 times the diameter of the armature in centimetres, while for drum armatures the volume is obtained by multiplying the diameter by 600. The cylinder armature has for a given volume a large diameter, because of the influence of the interior wires. These being heaped inside to one and a half or twice the depth of the exterior winding, also being longer, a larger diameter is required for a given volume, both from efficiency and temperature considerations. Necessarily, the relations here given are not of a hard and fast character, and may be varied considerably. But whatever the proportion adopted, it is absolutely essential that the sparking limit already considered be not too closely approached.

OUTPUT OF DIRECT CURRENT ARMATURES.

If we call N the total number of lines of force entering the armature from all the poles, however many, and n the number of revolutions per second, the average E. M. F. generated in each conductor is, of course, $\mathrm{N}\,n\,10^{-8}$. If C be the total current flowing, each conductor will carry, with the sections coupled in the ordinary way, $\frac{\mathrm{C}}{p}$ amperes, p being the number of poles. The electrical work due to each conductor is $\frac{\mathrm{C}}{p} \times \frac{\mathrm{N}\,n}{10^8}$; and the total work, $\frac{w\,\mathrm{C}}{p} \times \frac{\mathrm{N}\,n}{10^8}$, where w is the number of conductors, counted all round the exterior of the armature. The quantity $\frac{w\,\mathrm{C}}{p}$ is what we have called the *volume*, and we get for the total electrical output, in watts, the expression

$$\mathrm{W} = \mathrm{N}\,n\,v\,10^{-8},$$

which is quite independent of the manner of coupling up the armature sections. It will be evident, I think, that with the same relation existing between v and d for two, four, and six poles, the output of an armature of given diameter and length, running at the same speed, is quite independent of the number of poles. It matters not whether N be furnished by two poles only, or by four poles of half the angular width, provided its value remains unaltered.

The volume, then, may be expressed in terms of the diameter. The quantity N may be expressed in terms of the diameter × length of the armature. Taking an induction of 5,000 C. G. S. units per square centimetre in the air gap—a very usual figure—and assuming that the fraction of the armature circumference covered by the pole-pieces = 2.25 d, we get, calling L the length of the armature in centimetres, 11,250 $d\,L$ as the total number of lines of force entering the core. Call this, in round numbers, 12,000 $d\,L$. Substituting for N and v their values, the output becomes for cylinder armatures

$$\mathrm{W} = .048\, d^2\, Ln$$

and for drum armatures

$$\mathrm{W} = .072\, d^2\, Ln.$$

This applies to all direct current machines, whether bi-polar or multipolar; though it will be understood, of course, that the induction in the gap may be greater or less than what has been assumed. In that case the co-efficients .048 and .072 would be altered, without changing, however, the form of the expression.

SOME POSSIBLE MODIFICATIONS IN THE METHODS OF PROTECTING BUILDINGS FROM LIGHTNING.[1]

BY N. D. C. HODGES.

Ordinarily a lightning-rod is regarded as a conduit or pipe for conveying electricity from a cloud to the ground. The idea is that a certain quantity of electricity has to get to the ground somehow; that if an easy channel is opened for it, the electricity will pass quietly and safely; but that if obstruction is introduced, violence and damage will result. This being the notion of what is required, a stout copper rod, a wide-branching and deep-reaching system of roots to disperse the charge as fast as the rod brings it down, and a supplement of sharp points at a good elevation to tempt the discharge into this attractive thoroughfare, are naturally guaranties of complete security.

I think Oliver J. Lodge has expressed well the difficulty that has always been present in my mind when I have read detailed descriptions of the effects of lightning. He says, in a paper published in THE ELECTRICAL ENGINEER some time last June, that when, in spite of all precautions, accidents still occured; when it was found that from the best-constructed conductors flashes were apt to spit off in a senseless manner to gun-barrels and bell-ropes, and wire fences and water-butts, it was the custom to more or less ridicule and condemn either the proprietor or the erector, or both, and to hint that if only something different had been done, say, for instance, if glass insulators had not been used, or if the rod had not been stapled too tightly into the wall, or if the rope had not been made of standard wires, or if copper had been used instead of iron, or if the finials had been more sharply pointed, or if the earth plate had been more deeply buried, or if the rainfall had not been so small, or if the testing of the conductor for resistance had been more recent, or if the wall to which the rod was fixed had been kept wet,—then the damage would not have happened. Every one of these excuses has been appealed to as an explanation of a failure; but because the easiest thing to abuse has always been the buried earth connection that has come in for the most frequent blame, and has been held responsilbe for every accident not otherwise explicable.

The ordinary theory of the formation of the high potentials that are manifested in lightning-discharges is simply this, That if, in the cloud, there is a certain quantity of electricity distributed on a given mass of fine mist, it will exist there at a certain potential, depending on the capacity of this finely divided matter. Now, if these mist-particles coalesce into raindrops, the thoeory points out that there would be a decrease in potential of the charge. It occurred to me immediately, that, if this theory had any foundation in fact, it ought to be possible to reverse the operation on the surface of the earth; that is, to receive the lightning-discharge on some large body, which would then be broken up into fine particles of vapor, which would have a considerably greater electrical capacity, and that the potential of the discharge would thereby be materially reduced, and the effects of the lightning mitigated. This was my hypothesis to work upon, and I immediately began to look through the records to see what actually happened in the case of lightning discharges, and to see if there was any support in fact for my hypothesis.

The first book at hand was Sir William Thomson's "Papers on Electricity and Magnetism," and I found that he described in detail the case of a farmhouse in Scotland, which was struck by lightning, and in which this very dissipating effect took place; that is, the bell-wires were dissipated,—an occurrence which, as you know, is extremely common when a lightning-discharge takes place. I went on through the records, and found numberless cases of this, the oldest being that of the dissipation of the metal covering on the wooden shield of some Greek warrior. I mention this case as of interest, as it brings out a very fortunate circumstance, that when thin metal is dissipated against wood or even against plaster, no harm results to the wood or plaster. Of course, you know that it has been somewhat discussed whether this action is a dissipation through the heating of the metal, or whether it is a cold dissipation—a breaking-up into particles, as it were—of the metal. On this point I have nothing to say.

---

[1] Abstract of a paper read before the American Institute of Electrical Engineers, April 21, 1891.

But as I went on through the records I could not make the facts accord satisfactorily with my hypothesis. The dissipating action that I was looking for certainly took place, and is a very common accompaniment of lightning-discharges, but in spite of it, there was damage to the building. It was only after a considerable reading of the records that it gradually dawned on me that I had found no case where damage to the building occurred on the same level with the dissipated conductor.

The author then described in Franklin's own words a typical case of the action of a small conductor dissipated by the discharge.

I would thus formulate what seems to be true,—that a conductor which can be easily dissipated by a lightning-discharge protects the building to which it is attached between two horizontal planes, the one passing through the upper end of the dissipated conductor, and the other through the lower end; and it is this one point that I would urge upon the consideration of the Institute. So far as I know, therefore, a conductor such as I have here—a conductor made of light copper ribbon, so that 75 feet of it will weigh only a pound, and made in sections two feet long, which shall be tacked to the building from its ridge-pole to the foundation, the joints being made of low conductivity by the insertion of insulating washers—will protect the building. The conductor will be destroyed by the discharge. Its destruction can take place even against a plastered wall without injury to the wall; but no other harm will occur so far as the conductor extends in a vertical direction. There is no need of the conductor following the shortest course to the ground. There is no need of providing a good earth connection. I can see no difference between the two ends of the metallic ribbon. You do not attempt to make a good connection at the top with the dielectric, and I do not see why you should attempt to make a good connection at the bottom. In no case on record of the protecting influence of dissipatable conductors has this protecting influence depended upon there being a good earth connection. Of course, the ribbon should not be boarded over. Free gun-powder burns harmlessly enough, but it causes damage when burned in a confined space; and the dissipation of a conductor presents similar phenomena. It would not do to run such a conductor as I suggest here part way down the building, and then make it turn up again before its final descent to the ground, as in such a case there would probably be a line of disaster from the point where the upward turn began.

In order to destroy a building in whole or in part, it is necessary that work should be done; that is, energy is required. Just before the lightning-discharge takes place, the energy capable of doing the damage which we seek to prevent exists mainly in the column of air extending from the cloud to the earth in some form that makes it capable of appearing as what we call electricity. We will therefore call it electrical energy. What this electrical energy is, it is not necessary for us to consider; but that it exists there can be no doubt, as it manifests itself in the destruction of buildings.
